Mendota Pool Bypass and Reach 2B Improvements Project

Draft
Environmental Impact Statement/Report

SAN JOAQUIN RIVER
RESTORATION PROGRAM

State Clearinghouse No. 2009072044

Draft
June 2015

Table of Contents

S. Executive Summary S-1
S.1 Introduction and Background S-1
S.1.1 Stipulation of Settlement S-5
S.1.2 San Joaquin River Restoration Program S-6
S.2 Purpose and Uses of this Project EIS/R S-7
S.3 Scoping and Public Involvement Process S-8
S.4 Purpose and Need for Action and Project Objectives S-9
S.5 Project Study Area S-10
S.6 Alternatives Evaluated in this EIS/R S-11
S.6.1 No-Action/No-Project Alternative S-12
S.6.2 Alternative A S-13
S.6.3 Alternative B S-13
S.6.4 Alternative C S-13
S.6.5 Alternative D S-14
S.6.6 Elements Common to All Action Alternatives S-23
S.7 Environmental Commitments S-26
S.7.1 Conservation Strategy S-26
S.7.2 Minimize Flood Risk from Interim and Restoration Flows S-29
S.7 Areas of Known Controversy and Issues to be Resolved S-30
S.8 Consensus-Based Alternative Selection S-31
S.9 Summary and Comparison of Impacts and Mitigation Measures S-32

1.0 Introduction 1-1
1.1 Background 1-1
1.1.1 Stipulation of Settlement 1-2
1.1.2 San Joaquin River Restoration Program 1-3
1.1.3 Overview of the Mendota Pool Bypass and Reach 2B Improvements 1-4
1.1.4 Scoping and Public Involvement Process 1-7
1.2 Purpose and Uses of this EIS/R 1-8
1.2.1 National Environmental Policy Act 1-8
1.2.2 California Environmental Quality Act 1-9
1.2.3 Type of Environmental Document 1-10
1.2.4 Compliance and Permits Supported by this EIS/R 1-11
1.3 Relationship to Other SJRRP NEPA and CEQA Documents 1-12
1.4 Purpose and Need for Action and Project Objectives 1-13

1.5 Responsibilities of Lead Agencies, Responsible Agency, and Implementing Agencies 1-14
1.6 Project Study Area 1-14
1.6.1 Geographic Area Description 1-14
1.6.2 Description of Existing Conditions within the Study Area 1-15
1.6.3 Description of Local Hydrology 1-21
1.7 Organization of this EIS/R 1-22

2.0 Description of Alternatives 2-1
2.1 Alternatives Formulation Process 2-1
2.1.1 Alternatives Development Process Overview 2-1
2.1.2 Stakeholder Involvement 2-2
2.1.3 Initial Options Formulation 2-7
2.1.4 Alternatives Formulation 2-8
2.1.5 Summary of the Alternatives Evaluation Process 2-9
2.2 Description of Alternatives 2-12
2.2.1 NEPA and CEQA Requirements 2-12
2.2.2 Overview of Alternatives 2-13
2.2.3 No-Action Alternative 2-14
2.2.4 Elements Common to All Action Alternatives 2-15
2.2.5 Alternative A (Compact Bypass with Narrow Floodplain and South Canal) 2-33
2.2.6 Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative 2-47
2.2.7 Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal) 2-63
2.2.8 Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal) 2-76
2.2.9 Alternatives Comparison Tables 2-84
2.2.10 Environmental Commitments 2-85
2.3 Alternatives Considered and Eliminated from Further Consideration 2-107
2.3.1 Pre-Initial Options Analysis 2-108
2.3.2 Pre-Evaluation Screening 2-110
2.3.3 Initial Alternatives Screening 2-113

3.0 Considerations for Describing the Affected Environment and Environmental Consequences 3-1
3.1 Study Area 3-1
3.1.1 Reach 2 3-1

3.1.2 Reach 3 3-2
3.1.3 Chowchilla Bypass 3-2
3.1.4 Delta-Mendota Canal 3-2
3.1.5 Mendota Pool 3-2
3.1.6 Fresno Slough 3-4
3.2 Chapter Contents and Definition of Terms 3-4
3.2.1 NEPA and CEQA Requirements 3-4
3.2.2 Significance Criteria 3-6
3.2.3 Impact Comparisons and Definitions 3-7
3.2.4 Impact Levels 3-8
3.2.5 Mitigation Measures 3-9
3.2.6 Significance After Mitigation 3-9
3.2.7 Relationship between Short-Term Uses of the Environment and Maintenance and Enhancement of Long-Term Productivity 3-10
3.2.8 Irreversible and Irretrievable Commitments of Resources 3-10
3.3 Resources Eliminated from Further Analysis 3-10

4.0 Air Quality 4-1
4.1 Environmental Setting 4-1
4.1.1 Ambient Air Quality 4-1
4.1.2 Sensitive Receptors 4-16
4.2 Regulatory Setting 4-17
4.2.1 Federal 4-17
4.2.2 State of California 4-20
4.2.3 Regional and Local 4-23
4.3 Environmental Consequences and Mitigation Measures 4-28
4.3.1 Impact Assessment Methodology 4-28
4.3.2 Significance Criteria 4-30
4.3.3 Impacts and Mitigation Measures 4-31

5.0 Biological Resources – Fisheries 5-1
5.1 Environmental Setting 5-1
5.1.1 Aquatic Habitat 5-1
5.1.2 Aquatic Foodweb 5-2
5.1.3 Aquatic Species Known to Occur in the Project Area and Vicinity 5-3
5.1.4 Special Status Species 5-5
5.2 Regulatory Setting 5-11

5.2.1 Federal 5-11
5.2.2 State of California 5-13
5.2.3 Regional and Local 5-15
5.3 Environmental Consequences and Mitigation Measures 5-16
5.3.1 Impact Assessment Methodology 5-16
5.3.2 Significance Criteria 5-17
5.3.3 Impacts and Mitigation Measures 5-18

6.0 Biological Resources – Vegetation 6-1
6.1 Environmental Setting 6-1
6.1.1 Regional Setting 6-1
6.1.2 Project Setting 6-2
6.2 Regulatory Setting 6-13
6.2.1 Federal 6-14
6.2.2 State of California 6-14
6.2.3 Regional and Local 6-16
6.3 Environmental Consequences and Mitigation Measures 6-18
6.3.1 Impact Assessment Methodology 6-18
6.3.2 Significance Criteria 6-20
6.3.3 Impacts and Mitigation Measures 6-21

7.0 Biological Resources - Wildlife 7-1
7.1 Environmental Setting 7-1
7.1.1 Regional Setting 7-1
7.1.2 Project Area 7-2
7.1.3 Special-Status Wildlife Species 7-8
7.2 Regulatory Setting 7-17
7.2.1 Federal 7-17
7.2.2 State of California 7-18
7.2.3 Regional and Local 7-20
7.3 Environmental Consequences and Mitigation Measures 7-21
7.3.1 Impact Assessment Methodology 7-21
7.3.2 Significance Criteria 7-23
7.3.3 Impacts and Mitigation Measures 7-24

8.0 Climate Change and Greenhouse Gas Emissions 8-1
8.1 Environmental Setting 8-1
8.1.1 Greenhouse Gases 8-1
8.1.2 Temperature, Precipitation, and Runoff 8-6

8.2 Regulatory Setting 8-11
8.2.1 Federal 8-11
8.2.2 State of California 8-12
8.2.3 Regional and Local 8-15
8.3 Environmental Consequences and Mitigation Measures 8-15
8.3.1 Impact Assessment Methodology 8-15
8.3.2 Significance Criteria 8-16
8.3.3 Impacts and Mitigation Measures 8-17

9.0 Cultural Resources 9-1
9.1 Environmental Setting 9-1
9.1.1 Regional Setting 9-1
9.1.2 Resources in the Project Area 9-8
9.2 Regulatory Setting 9-13
9.2.1 Federal 9-13
9.2.2 State of California 9-16
9.2.3 Local and Regional 9-17
9.3 Environmental Consequences and Mitigation Measures 9-17
9.3.1 Impact Assessment Methodology 9-17
9.3.2 Significance Criteria 9-18
9.3.3 Impacts and Mitigation Measures 9-20

10.0 Environmental Justice 10-1
10.1 Environmental Setting 10-1
10.1.1 Social and Demographic Characteristics 10-3
10.1.2 Long-term Challenges for Agricultural Lands 10-9
10.2 Regulatory Setting 10-9
10.2.1 Federal 10-9
10.2.2 State of California 10-10
10.2.3 Regional and Local 10-10
10.3 Environmental Consequences and Mitigation Measures 10-11
10.3.1 Impact Assessment Methodology 10-11
10.3.2 Disproportionately High and Adverse Criteria 10-11
10.3.3 Impacts and Mitigation Measures 10-12

11.0 Geology and Soils 11-1
11.1 Environmental Setting 11-1
11.1.1 Geology 11-1
11.1.2 Soils 11-4

11.1.3 Erosion and Sedimentation 11-10
11.1.4 Geomorphology 11-13
11.1.5 Soil Hazards 11-16
11.1.6 Mineral Resources 11-16
11.1.7 Seismicity and Neotectonics 11-22
11.2 Regulatory Setting 11-27
11.2.1 Federal 11-27
11.2.2 State of California 11-28
11.2.3 Regional and Local 11-28
11.3 Environmental Consequences and Mitigation Measures 11-29
11.3.1 Impact Assessment Methodology 11-29
11.3.2 Significance Criteria 11-30
11.3.3 Impacts and Mitigation Measures 11-31

11.0 Geology and Soils 11-1
11.1 Environmental Setting 11-1
11.1.1 Geology 11-1
11.1.2 Soils 11-3
11.1.3 Erosion and Sedimentation 11-8
11.1.4 Geomorphology 11-12
11.1.5 Soil Hazards 11-13
11.1.6 Mineral Resources 11-15
11.1.7 Seismicity and Neotectonics 11-17
11.2 Regulatory Setting 11-22
11.2.1 Federal 11-22
11.2.2 State of California 11-23
11.2.3 Regional and Local 11-23
11.3 Environmental Consequences and Mitigation Measures 11-24
11.3.1 Impact Assessment Methodology 11-24
11.3.2 Significance Criteria 11-25
11.3.3 Impacts and Mitigation Measures 11-26

12.0 Hydrology - Flood Management 12-1
12.1 Environmental Setting 12-1
12.1.1 Historical Perspective of Flood Protection in the San Joaquin River Basin 12-1
12.1.2 Flood Management Structures 12-2
12.1.3 Flood Management Operations and Conditions 12-5
12.1.4 Flood Management Agencies 12-9

12.2 Regulatory Setting 12-11
12.2.1 Federal 12-11
12.2.2 State of California 12-12
12.2.3 Regional and Local 12-12
12.3 Environmental Consequences and Mitigation Measures 12-13
12.3.1 Impact Assessment Methodology 12-13
12.3.2 Significance Criteria 12-13
12.3.3 Impacts and Mitigation Measures 12-14

13.0 Hydrology – Groundwater 13-1
13.1 Environmental Setting 13-1
13.1.1 Regional Setting 13-1
13.1.2 Project Setting 13-12
13.2 Regulatory Setting 13-13
13.2.1 Federal 13-13
13.2.2 State of California 13-14
13.2.3 Regional and Local 13-15
13.3 Environmental Consequences and Mitigation Measures 13-15
13.3.1 Impact Assessment Methodology 13-15
13.3.2 Significance Criteria 13-18
13.3.3 Impacts and Mitigation Measures 13-19

14.0 Hydrology - Surface Water Resources and Water Quality 14-1
14.1 Environmental Setting 14-1
14.1.1 Physical Conditions 14-1
14.1.2 Surface Water Resources 14-3
14.1.3 Geomorphology 14-7
14.1.4 Water Quality 14-17
14.2 Regulatory Setting 14-22
14.2.1 Federal 14-23
14.2.2 State of California 14-25
14.2.3 Regional and Local 14-29
14.3 Environmental Consequences and Mitigation Measures 14-30
14.3.1 Impact Assessment Methodology 14-30
14.3.2 Significance Criteria 14-31
14.3.3 Impacts and Mitigation Measures 14-32

15.0 Hydrology - Wetlands and Aquatic Resources 15-1
15.1 Environmental Setting 15-1

15.1.1 Existing Conditions 15-1
15.1.2 Categories for Wetlands and Other Waters of the United States 15-1
15.2 Regulatory Setting 15-4
15.2.1 Federal 15-5
15.2.2 State of California 15-6
15.2.3 Regional and Local 15-7
15.3 Environmental Consequences and Mitigation Measures 15-8
15.3.1 Impact Assessment Methodology 15-8
15.3.2 Significance Criteria 15-9
15.3.3 Impacts and Mitigation Measures 15-10

16.0 Land Use Planning and Agricultural Resources 16-1
16.1 Environmental Setting 16-1
16.1.1 Land Ownership 16-1
16.1.2 Land Use 16-3
16.1.3 Agricultural Production 16-3
16.1.4 Land Use Planning 16-9
16.2 Regulatory Setting 16-10
16.2.1 Federal 16-10
16.2.2 State of California 16-11
16.2.3 Regional and Local 16-15
16.3 Environmental Consequences and Mitigation Measures 16-16
16.3.1 Impact Assessment Methodology 16-16
16.3.2 Significance Criteria 16-17
16.3.3 Impacts and Mitigation Measures 16-18

17.0 Noise and Vibration 17-1
17.1 Environmental Setting 17-1
17.1.1 Fundamentals of Acoustics 17-1
17.1.2 Ambient Noise Measurements 17-5
17.2 Regulatory Setting 17-9
17.2.1 Federal 17-10
17.2.2 State of California 17-11
17.2.3 Regional and Local 17-13
17.3 Environmental Consequences and Mitigation Measures 17-15
17.3.1 Impact Assessment Methodology 17-15
17.3.2 Significance Criteria 17-20
17.3.3 Impacts and Mitigation Measures 17-23

18.0 Paleontological Resources 18-1
18.1 Environmental Setting 18-1
18.1.1 Physiographic Environment 18-1
18.1.2 Geologic Setting 18-1
18.1.3 Local Paleontological Resources 18-2
18.2 Regulatory Setting 18-4
18.2.1 Federal 18-4
18.2.2 State of California 18-5
18.2.3 Regional and Local 18-5
18.3 Environmental Consequences and Mitigation Measures 18-6
18.3.1 Impact Assessment Methodology 18-6
18.3.2 Significance Criteria 18-8
18.3.3 Impacts and Mitigation Measures 18-8

19.0 Public Health and Hazardous Materials 19-1
19.1 Environmental Setting 19-1
19.1.1 Known Hazardous Material Sites 19-2
19.1.2 Exposure to Disease 19-3
19.2 Regulatory Setting 19-4
19.2.1 Federal 19-4
19.2.2 State of California 19-6
19.2.3 Regional and Local 19-9
19.3 Environmental Consequences and Mitigation Measures 19-9
19.3.1 Impact Assessment Methodology 19-10
19.3.2 Significance Criteria 19-10
19.3.3 Impacts and Mitigation Measures 19-11

20.0 Recreation 20-1
20.1 Environmental Setting 20-1
20.1.1 Recreation Uses 20-1
20.1.2 Recreation Facilities and Areas 20-3
20.1.3 Public Access 20-4
20.2 Regulatory Setting 20-5
20.2.1 Federal 20-5
20.2.2 State of California 20-5
20.2.3 Regional and Local 20-6
20.3 Environmental Consequences and Mitigation Measures 20-6
20.3.1 Impact Assessment Methodology 20-6

20.3.2 Significance Criteria 20-7
20.3.3 Impacts and Mitigation Measures 20-8

21.0 Socioeconomics and Economics 21-1
21.1 Environmental Setting 21-1
21.1.1 Population Trends 21-1
21.1.2 Housing 21-3
21.1.3 Economic Base 21-4
21.1.4 Fiscal Resources of Local Governments 21-6
21.1.5 Value of Agricultural Production 21-8
21.1.6 Fiscal Resources of the Levee District 21-11
21.2 Regulatory Setting 21-13
21.2.1 Federal 21-13
21.2.2 State of California 21-13
21.2.3 Regional and Local 21-13
21.3 Environmental Consequences and Mitigation Measures 21-13
21.3.1 Impact Assessment Methodology 21-13
21.3.2 Significance Criteria 21-16
21.3.3 Impacts and Mitigation Measures 21-16

22.0 Transportation and Traffic 22-1
22.1 Environmental Setting 22-1
22.1.1 Roadway Network 22-1
22.1.2 Study Roadway Segments 22-3
22.1.3 Existing Traffic Volume 22-3
22.1.4 Existing Level of Service 22-4
22.2 Regulatory Setting 22-5
22.2.1 Federal 22-5
22.2.2 State of California 22-5
22.2.3 Regional and Local 22-8
22.3 Environmental Consequences and Mitigation Measures 22-8
22.3.1 Impact Assessment Methodology 22-8
22.3.2 Significance Criteria 22-11
22.3.3 Impacts and Mitigation Measures 22-12

23.0 Utilities and Service Systems 23-1
23.1 Environmental Setting 23-1
23.1.1 Wastewater Collection 23-1
23.1.2 Fire Protection Services 23-1

23.1.3 Law Enforcement Services 23-3
23.1.4 Emergency Services 23-4
23.1.5 Solid Waste Management 23-5
23.1.6 Utility Crossings 23-6
23.1.7 Energy 23-8
23.1.8 Water Supply Features 23-8
23.2 Regulatory Setting 23-9
23.2.1 Federal 23-9
23.2.2 State of California 23-10
23.2.3 Regional and Local 23-11
23.3 Environmental Consequences and Mitigation Measures 23-14
23.3.1 Impact Assessment Methodology 23-14
23.3.2 Significance Criteria 23-15
23.3.3 Impacts and Mitigation Measures 23-17

24.0 Visual Resources 24-1
24.1 Environmental Setting 24-1
24.1.1 Critical Public Views 24-1
24.1.2 Existing Visual Conditions 24-6
24.2 Regulatory Setting 24-28
24.2.1 Federal 24-28
24.2.2 State of California 24-28
24.2.3 Regional and Local 24-28
24.3 Environmental Consequences and Mitigation Measures 24-30
24.3.1 Impact Assessment Methodology 24-30
24.3.2 Significance Criteria 24-30
24.3.3 Impacts and Mitigation Measures 24-31

25.0 Cumulative Impacts 25-1
25.1 Definitions of Cumulative Effects 25-1
25.2 Methods and Assumptions 25-2
25.2.1 Past and Present Actions 25-3
25.2.2 Reasonably Foreseeable Probable Future Actions 25-3
25.3 Significance Criteria 25-10
25.4 Mitigation Measures for Significant Cumulative Impacts 25-10

25.0 Cumulative Impacts 25-1
25.1 Definitions of Cumulative Effects 25-1
25.2 Methods and Assumptions 25-2

25.2.1 Past and Present Actions 25-3
25.2.2 Reasonably Foreseeable Probable Future Actions 25-3
25.3 Significance Criteria 25-10
25.4 Mitigation Measures for Significant Cumulative Impacts 25-10
25.5 Cumulative Effects Analysis 25-11
25.5.1 Air Quality 25-12
25.5.2 Biological Resources – Fisheries 25-13
25.5.3 Biological Resources – Vegetation 25-15
25.5.4 Biological Resources – Wildlife 25-16
25.5.5 Climate Change and Greenhouse Gas Emissions 25-17
25.5.6 Cultural Resources 25-18
25.5.7 Environmental Justice 25-19
25.5.8 Geology and Soils 25-19
25.5.9 Hydrology – Flood Management 25-20
25.5.10 Hydrology – Groundwater 25-20
25.5.11 Hydrology – Surface Water Resources and Water Quality 25-22
25.5.12 Hydrology – Wetlands and Aquatic Resources 25-22
25.5.13 Land-Use Planning and Agricultural Resources 25-24
25.5.14 Noise and Vibration 25-25
25.5.15 Paleontological Resources 25-26
25.5.16 Public Health and Hazardous Materials 25-26
25.5.17 Recreation 25-27
25.5.18 Socioeconomics and Economics 25-28
25.5.19 Transportation and Traffic 25-29
25.5.20 Utilities and Service Systems 25-30
25.5.21 Visual Resources 25-30

26.0 Other NEPA and CEQA Considerations 26-1
26.1 Significant and Unavoidable Impacts 26-1
26.1.1 Construction-Related Air Pollutants 26-3
26.1.2 Agricultural Resources 26-3
26.1.3 Emergency Response Times 26-3
26.2 Relationship between Short-Term Uses and Long-Term Productivity 26-4
26.3 Irreversible and Irretrievable Commitments of Resources 26-5
26.4 Growth-Inducing Impacts 26-6
26.5 Preferred Alternative 26-7
26.6 Environmentally Preferable/Superior Alternative 26-8
26.7 Least Environmentally Damaging Practicable Alternative 26-9

26.8 Comparison of Action Alternatives 26-10
26.8.1 Air Quality 26-10
26.8.2 Biological Resources – Fisheries 26-10
26.8.3 Biological Resources – Vegetation 26-14
26.8.4 Biological Resources – Wildlife 26-14
26.8.5 Climate Change and Greenhouse Gas Emissions 26-15
26.8.6 Cultural Resources 26-15
26.8.7 Environmental Justice 26-15
26.8.8 Geology and Soils 26-16
26.8.9 Hydrology – Flood Management 26-16
26.8.10 Hydrology – Groundwater 26-16
26.8.11 Hydrology – Surface Water Resources and Water Quality 26-16
26.8.12 Hydrology – Wetlands and Aquatic Resources 26-17
26.8.13 Land-Use Planning and Agricultural Resources 26-17
26.8.14 Noise and Vibration 26-17
26.8.15 Paleontological Resources 26-17
26.8.16 Public Health and Hazardous Materials 26-17
26.8.17 Recreation 26-18
26.8.18 Socioeconomics and Economics 26-18
26.8.19 Transportation and Traffic 26-18
26.8.20 Utilities and Service Systems 26-18
26.8.21 Visual Resources 26-18
26.9 Mitigation Monitoring and Reporting Program 26-19
26.9.1 Matrix 26-19
26.9.2 Environmental Commitments 26-35

27.0 Consultation, Coordination, and Compliance 27-1
27.1 Compliance with Related Laws, Rules, Regulations, and Executive Orders 27-1
27.1.1 Federal Requirements 27-1
27.1.2 State Requirements 27-18
27.1.3 Local Plans and Policies 27-28
27.2 Consultation and Coordination 27-29
27.2.1 Project Scoping 27-29
27.2.2 Agencies and Organizations Consulted 27-40
27.2.3 Future Public Involvement 27-41
27.3 Distribution List 27-41

28.0 References 28-1
28.1 Chapter 1 – Introduction 28-1
28.2 Chapter 2 – Description of Alternatives 28-3
28.3 Chapter 3 – Considerations for Describing the Affected Environment and Environmental Consequences 28-6
28.4 Chapter 4 – Air Quality 28-6
28.5 Chapter 5 – Biological Resources – Fisheries 28-8
28.6 Chapter 6 – Biological Resources – Vegetation 28-12
28.7 Chapter 7 – Biological Resources – Wildlife 28-14
28.8 Chapter 8 – Climate Change and Greenhouse Gas Emissions 28-16
28.9 Chapter 9 – Cultural Resources 28-19
28.10 Chapter 10 – Environmental Justice 28-22
28.11 Chapter 11 – Geology and Soils 28-23
28.12 Chapter 12 – Hydrology – Flood Management 28-25
28.13 Chapter 13 – Hydrology – Groundwater 28-26
28.14 Chapter 14 – Hydrology – Surface Water Resources and Water Quality 28-28
28.15 Chapter 15 – Hydrology – Wetlands and Aquatic Resources 28-31
28.16 Chapter 16 – Land-Use Planning and Agricultural Resources 28-32
28.17 Chapter 17 – Noise and Vibration 28-34
28.18 Chapter 18 – Paleontological Resources 28-35
28.19 Chapter 19 – Public Health and Hazardous Materials 28-36
28.20 Chapter 20 – Recreation 28-38
28.21 Chapter 21 – Socioeconomics and Economics 28-40
28.22 Chapter 22 – Transportation and Traffic 28-42
28.23 Chapter 23 – Utilities and Service Systems 28-43
28.24 Chapter 24 – Visual Resources 28-45
28.25 Chapter 25 – Cumulative Impacts 28-46
28.26 Chapter 26 – Other NEPA and CEQA Considerations 28-46
28.27 Chapter 27 – Consultation, Coordination, and Compliance 28-46

SAN JOAQUIN RIVER RESTORATION PROGRAM

Draft

Mendota Pool Bypass and Reach 2B Improvements Project Environmental Impact Statement/ Environmental Impact Report

SCH # 2009072044

June 2015

The San Joaquin River Restoration Program is a comprehensive long-term effort to restore flows to the San Joaquin River from Friant Dam to the confluence of Merced River and restore a self-sustaining Chinook salmon fishery in the river while reducing or avoiding adverse water supply impacts from Interim and Restoration flows.

Mission Statements

The mission of the Bureau of Reclamation is to manage, develop and protect water and related resources in an environmentally and economically sound manner in the interest of the American Public.

CALIFORNIA STATE LANDS COMMISSION

The California State Lands Commission serves the people of California by providing stewardship of the lands, waterways, and resources entrusted to its care through economic development, protection, preservation, and restoration.

Executive Summary

Introduction and Background

Mendota Pool

The Mendota Pool Bypass and Reach 2B Improvements Project (Project) includes the construction, operation, and maintenance of the Mendota Pool Bypass and improvements in the San Joaquin River channel in Reach 2B (Figure S-1). The Project consists of a floodplain width that conveys at least 4,500 cubic feet per second (cfs), a method to bypass Restoration Flows around Mendota Pool, and a method to deliver water to Mendota Pool. The Project footprint and vicinity (Figure S-2) extend from approximately 0.3 mile above the Chowchilla Bifurcation Structure to approximately 1.0 mile below the Mendota Dam. The Project footprint comprises the area that could be directly affected by the Project. The Project study area or "Project area" includes areas directly and indirectly affected by the Project. The Project area is in Fresno and Madera counties, near the town of Mendota, California.

The Mendota Pool Bypass and Reach 2B improvements, defined in the Stipulation of Settlement in *Natural Resources Defense Council, et al., v. Kirk Rodgers, et al.* (Settlement), are (Settlement Paragraph 11[a]):

> *(1) Creation of a bypass channel around Mendota Pool to ensure conveyance of at least 4,500 cfs from Reach 2B downstream to Reach 3. This improvement requires construction of a structure capable of directing flow down the bypass and allowing the Secretary [of the Interior] to make deliveries of San Joaquin River water into Mendota Pool when necessary;*
>
> *(2) Modifications in channel capacity (incorporating new floodplain and related riparian habitat) to ensure conveyance of at least 4,500 cfs in Reach 2B between the Chowchilla Bifurcation Structure and the new Mendota Pool bypass channel.*

Because the functions of these channels may be inter-related, the design, environmental compliance, and construction of the two are being addressed as one project. The Project would be implemented consistent with the Settlement and the San Joaquin River Restoration Settlement Act (Act), with implementation dates clarified by the Draft Framework for Implementation (San Joaquin River Restoration Program [SJRRP] 2015).

Mendota Dam

Figure S-1. Overview of the SJRRP Restoration Area and the Project Vicinity

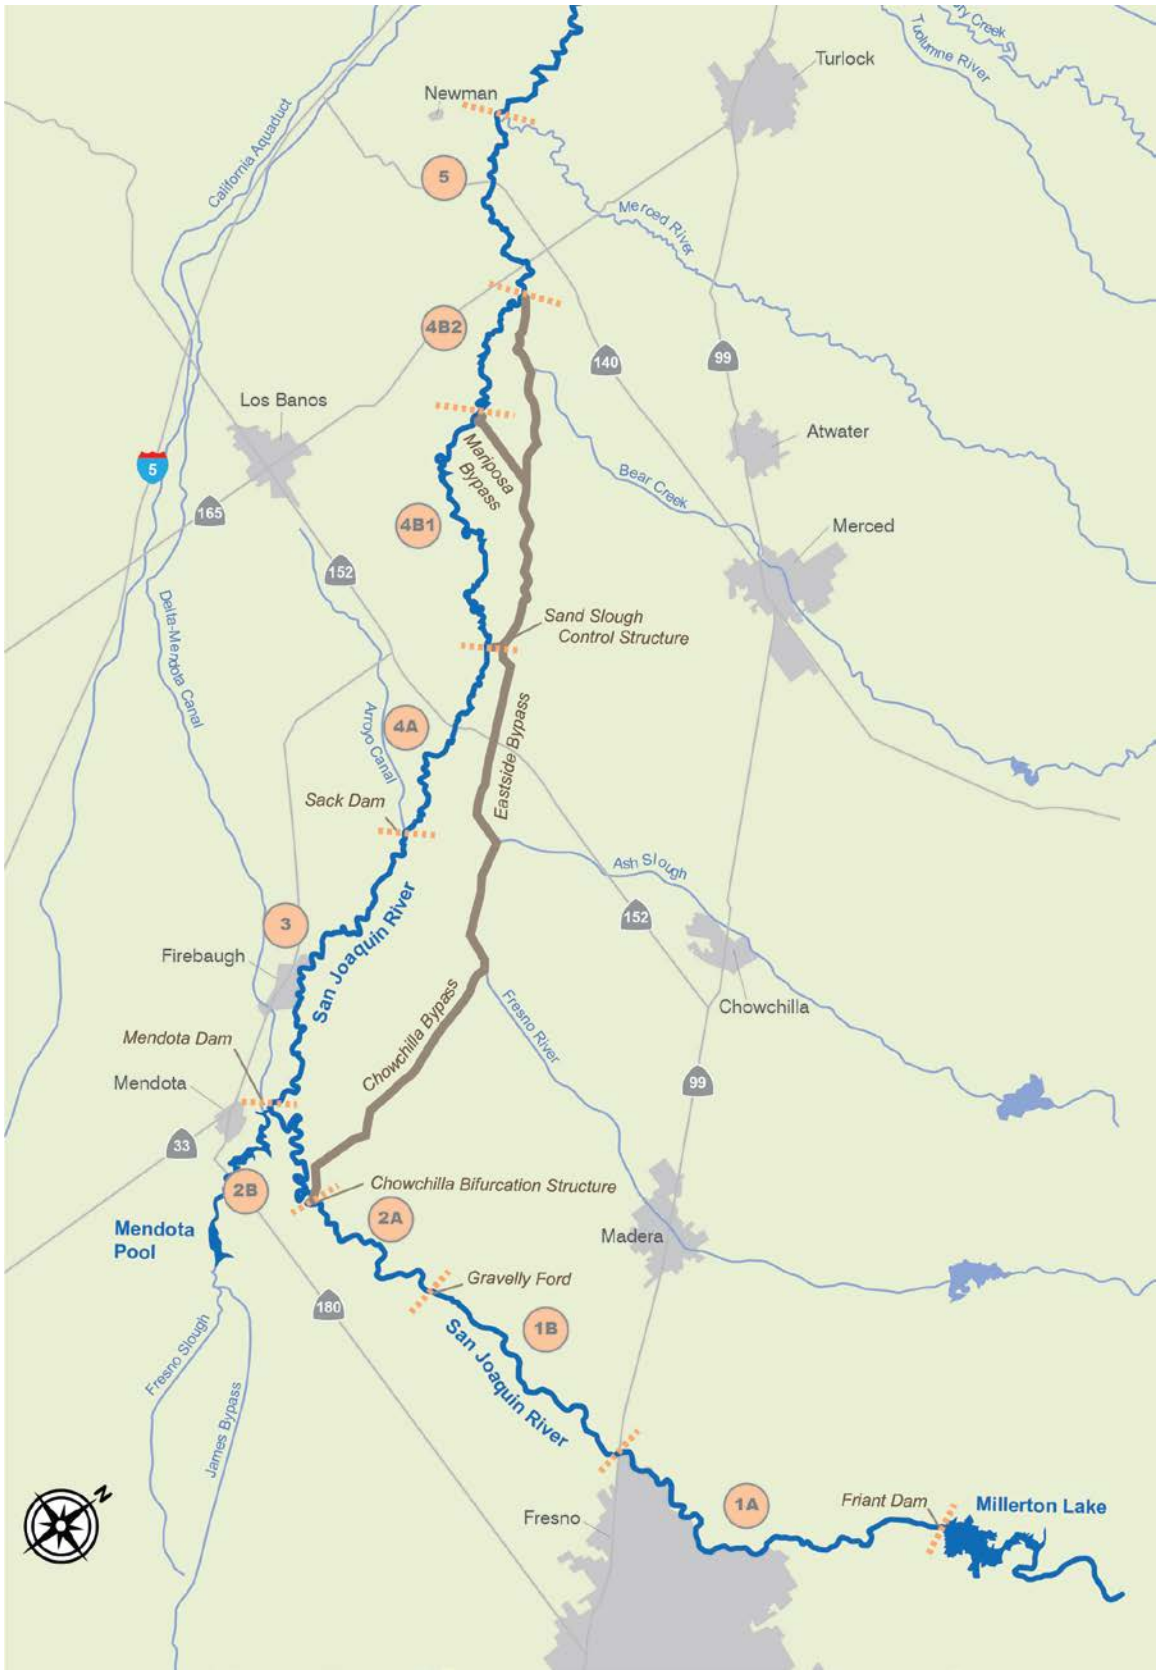

Figure S-2. Project Footprint and Vicinity

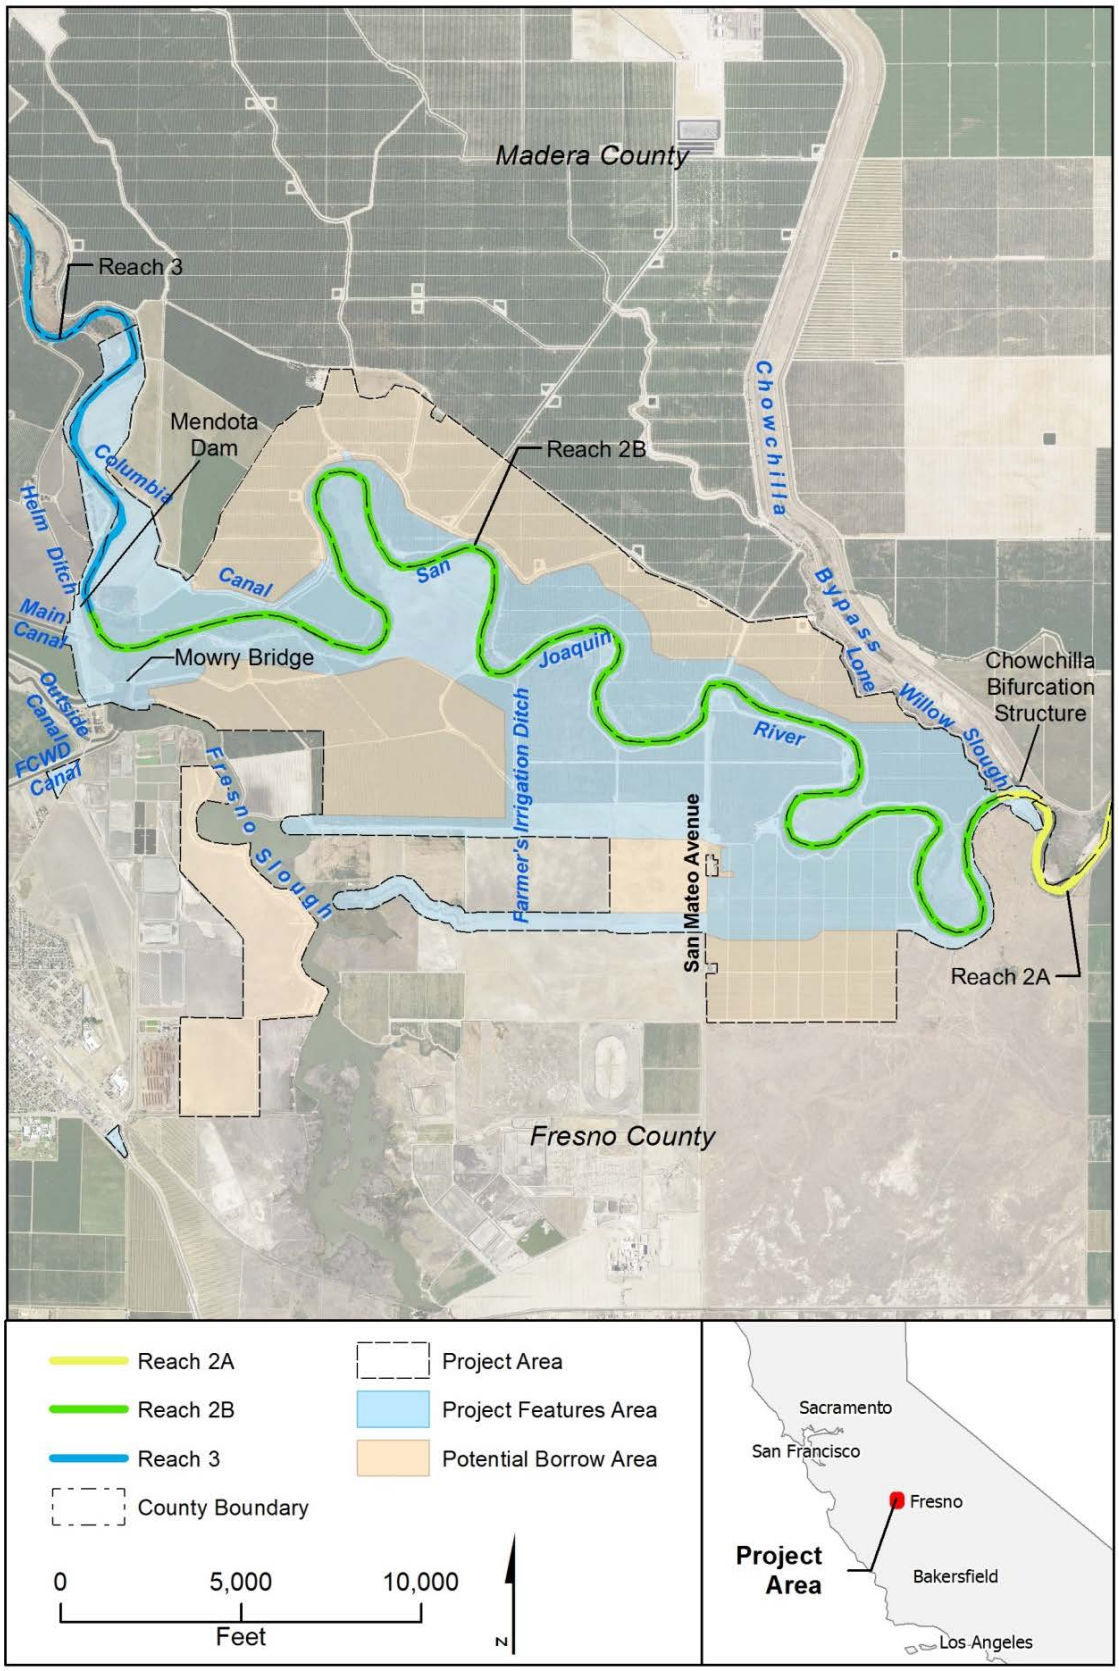


The Mendota Pool Bypass would include conveyance of at least 4,500 cfs around Mendota Pool (or the Pool) from Reach 2B to Reach 3 and a fish barrier, if appropriate, to direct upmigrating adult salmon into the bypass. The bypass could be accomplished by constructing a new channel around Mendota Pool or by limiting Mendota Pool to areas outside of the San Joaquin River. This action would include the ability to divert 2,500 cfs to the Pool if water deliveries are required for the San Joaquin River Exchange Contractors (Exchange Contractors) and may consist of a bifurcation structure in Reach 2B. The bifurcation structure would include a fish passage facility to enable up-migrating salmon to pass the structure and a fish screen, if appropriate, to direct out-migrating fish into the bypass channel and minimize or avoid fish entrainment to the Pool.

Headworks of the Main Canal

Improvements to Reach 2B would include modifications to the San Joaquin River channel from the Chowchilla Bifurcation Structure to the new Mendota Pool Bypass to provide a capacity of at least 4,500 cfs with integrated floodplain habitat. The options under consideration include potential levee setbacks along Reach 2B to increase the channel and floodplain capacity and provide for floodplain habitat. Floodplain habitat is included along the Reach 2B portion of the Project as required by the Settlement; floodplain habitat is being considered along the Mendota Pool Bypass channel because Central Valley floodplains have been shown to be of value to rearing juvenile salmon as they migrate downstream. In addition, the SJRRP Fisheries Management Plan (SJRRP 2010a) and Minimum Floodplain Habitat Area for Spring and Fall-Run Chinook Salmon report (SJRRP 2012) describe that sufficient floodplain habitat is an important feature for meeting salmon population targets.

This Executive Summary provides an overview of the Environmental Impact Statement/Environmental Impact Report (EIS/R) prepared pursuant to the National Environmental Policy Act (NEPA) and California Environmental Quality Act (CEQA). This EIS/R evaluates alternative ways to implement Paragraphs 11(a)(1) and 11(a)(2) of the Settlement, consistent with the Act in Public Law 111-11. U.S. Department of the Interior, Bureau of Reclamation (Reclamation) is the lead NEPA agency and California State Lands Commission (CSLC) is the lead CEQA agency in preparing this EIS/R.

Chowchilla Bifurcation Structure

Stipulation of Settlement

In 1988, a coalition of environmental groups, led by the Natural Resources Defense Council (NRDC), filed a lawsuit, known as *NRDC, et al., v. Kirk Rodgers, et al.*, challenging the renewal of long-term water service contracts between the United States and Central Valley Project (CVP) Friant Division contractors. On September 13, 2006, after more than 18 years of litigation, the Settling Parties, including NRDC, Friant Water Authority (FWA), and the U.S. Departments of the Interior and Commerce, agreed on the terms and conditions of a Settlement subsequently approved by the U.S. Eastern District Court of California on October 23, 2006. The Act, included in Public Law 111-11 and signed into law on March 30, 2009, authorizes and directs the Secretary of the Interior (Secretary) to implement the Settlement. The Settlement establishes two primary goals:

- **Restoration Goal** – To restore and maintain fish populations in "good condition" in the main stem San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally reproducing and self-sustaining populations of salmon and other fish.
- **Water Management Goal** – To reduce or avoid adverse water supply impacts on all of the Friant Division long-term contractors that may result from the Interim and Restoration flows provided for in the Settlement.

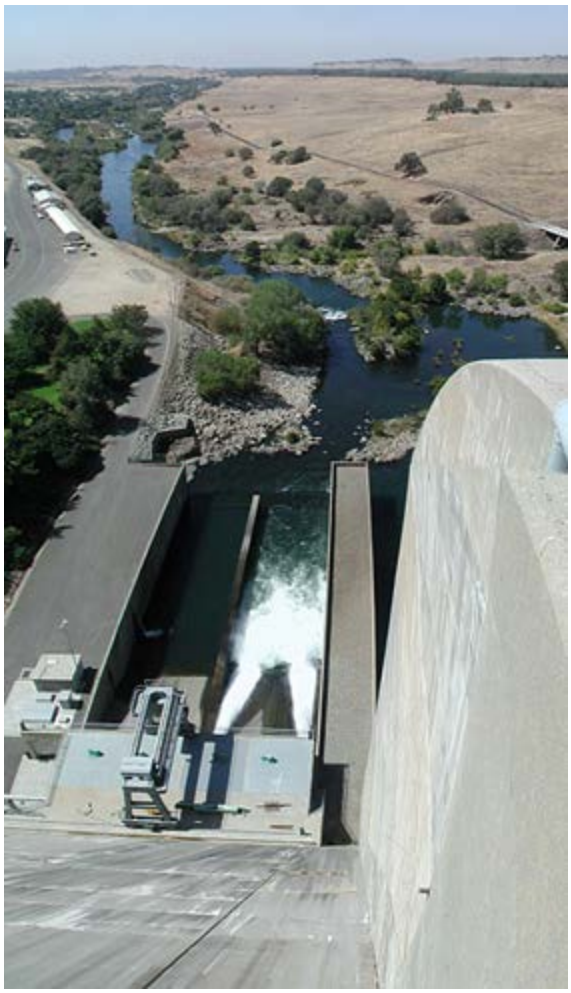
Chinook salmon

To achieve the Restoration Goal, the Settlement calls for releases of water from Friant Dam to the confluence of the Merced River (referred to as Interim and Restoration flows), a combination of channel and structural modifications along the San Joaquin River below Friant Dam, and reintroduction of Chinook salmon. Restoration Flows are specific volumes of water to be released from Friant Dam during different water year types, according to Exhibit B of the Settlement. Interim Flows are experimental flows that began in 2009 and ended December 2013 with the purpose of collecting relevant data concerning flows, temperatures, fish needs, seepage losses, recirculation, recapture, and reuse. Restoration Flows began January 1, 2014.

Orange groves within the Friant Division of the Central Valley Project

San Joaquin River Restoration Program

The SJRRP comprises several Federal and State of California (State) agencies responsible for implementing the Settlement. Implementing Agencies include Reclamation, U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NMFS), California Department of Water Resources (DWR), and California Department of Fish and Wildlife (DFW). In addition, the Settlement stipulates that a Technical Advisory Committee be established, comprising six members appointed by NRDC and FWA. The Settlement also calls for a Restoration Administrator (RA) to provide specific recommendations to the Secretary in coordination with the Technical Advisory Committee. The RA is responsible for consulting with the Secretary on implementing actions under Paragraph 11 of the Settlement, and for identifying and recommending additional actions under Paragraph 12 of the Settlement. In addition, the RA is responsible for consulting with the Secretary on the reintroduction of Chinook salmon under Paragraph 14 of the Settlement and flow releases under Paragraphs 13 and 15.



Releases from Friant Dam

Purpose and Uses of this Project EIS/R

The purpose of this EIS/R is to analyze the project-specific direct, indirect, and short term/long term impacts of implementing the Project as directed by the Act, consistent with NEPA/CEQA requirements. This EIS/R serves as an informational document for decision makers, public agencies, non-government organizations, and the general public regarding the potential direct and indirect environmental consequences of implementing any of the alternatives. This EIS/R supports the needed permits, petitions, and similar compliance, coordination, and consultation efforts for the Project actions.

As previously described, Reclamation is the lead NEPA agency and CSLC is the lead CEQA agency in preparing this EIS/R. The actions identified in this EIS/R include actions to be undertaken by Reclamation, as approved by CSLC. No sooner than 30 days after the final EIS/R is published, Reclamation will prepare a Record of Decision. Similarly, CSLC will take actions on whether to certify the EIR, approve the Project, and file a Notice of Determination.

The Settlement identifies the Secretary as the lead Federal entity responsible for implementation and USFWS as the lead Federal agency responsible for reintroduction of spring-run and fall-run Chinook salmon. The Secretary has designated Reclamation to act as the lead Federal entity responsible for implementation of the Settlement. The Settlement also identifies the Secretary of the U.S. Department of Commerce, through NMFS, as a necessary participant to allow for permitting the reintroduction of spring-run Chinook salmon. The Settlement also anticipated involvement of the California Natural Resources Agency through DWR and DFW. Therefore, the Settlement Implementing Agencies are Reclamation, USFWS, NMFS, DWR, and DFW.

Reclamation and CSLC have coordinated with the Settling Parties and Implementing Agencies in preparation of this EIS/R. In addition, several agencies accepted the invitation to participate as cooperating agencies under NEPA, including U.S. Environmental Protection Agency (EPA), the U.S. Army Corps of Engineers (Corps), NMFS, and Central California Irrigation District. The cooperating agencies have provided input that is being considered in preparation of this EIS/R.

San Joaquin River and Chowchilla Bypass

Scoping and Public Involvement Process

The lead agencies conducted public and stakeholder outreach activities to engage and inform all interested parties of Project activities. Engaging those interested parties helped to inform the process for scoping the Project alternatives and development of this EIS/R. Reclamation initiated the NEPA process by issuing a Notice of Intent on July 13, 2009, and DWR initiated the CEQA process by issuing a Notice of Preparation on the same day, to prepare an EIS/R and hold public scoping meetings. (Although initial CEQA actions were conducted by DWR, subsequent actions during the EIS/R process have been conducted by the CSLC as the State lead agency.)

The EIS/R scoping comment period began the date the Notice of Intent was issued and ended on August 14, 2009. The comments received were summarized in a Public Scoping Report released February 2010 (SJRRP 2010b). The NEPA scoping process also serves as the scoping process for compliance with other Federal laws such as the National Historic Preservation Act, Section 106.

Public involvement and outreach activities have enabled the Implementing Agencies to involve stakeholders and incorporate public and stakeholder input into the development of major Project documents, including this EIS/R. These activities seek to create an open and transparent process through which the general public, stakeholders, affected Third Parties, and other interested parties can track and participate in SJRRP activities, including the formulation of alternatives for this EIS/R. Ongoing public outreach activities conducted in support of the Project include the following:

- Hosting Project-specific landowner meetings as well as participating in SJRRP Technical Feedback Meetings with subject-matter experts, Settling Parties, affected stakeholders, and the general public to obtain information and viewpoints from individual attendees; provide updates on the status of Project work products; keep the Technical Feedback Group up-to-date with the current status of the Project; gather feedback on Project documents; and discuss potential opportunities and constraints that may arise.
- Making available technical memoranda and other milestone Project documents to the general public, stakeholders, affected Third Parties, and other interested parties on the SJRRP website.

Ornamental Palms in the Project Area

Purpose and Need for Action and Project Objectives

The purpose and objective of the Project are to implement portions of the Settlement consistent with the Act. The Act authorizes and directs the Secretary to implement the Settlement. Specifically, this Project is intended to implement Paragraphs 11(a)(1) and 11(a)(2) of the Settlement, which are authorized in Section 10004(a)(1) of the Act.

Paragraph 11(a)(1)

> *Creation of a bypass channel around Mendota Pool to ensure conveyance of at least 4,500 cfs from Reach 2B downstream to Reach 3. This improvement requires construction of a structure capable of directing flow down bypass and allowing the Secretary to make deliveries of San Joaquin River water into Mendota Pool when necessary;*

Paragraph 11(a)(2)

> *Modifications in channel capacity (incorporating new floodplain and related riparian habitat) to ensure conveyance of at least 4,500 cfs in Reach 2B between the Chowchilla Bifurcation Structure and the new Mendota Pool bypass Channel;*

The Settlement specifies the need, which requires modifications to Reach 2B and construction of a bypass around Mendota Pool in support of achieving the Restoration Goal (Settlement Paragraph 2):

> *... a goal of this Settlement is to restore and maintain fish populations in "good condition" in the main stem of the San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally-reproducing and self-sustaining populations of salmon and other fish (the "Restoration Goal").*

The purpose of providing increased channel capacity and floodplain and riparian habitat in Reach 2B responds to the need to restore and maintain fish populations in "good condition" by providing fish passage and rearing habitat which benefit salmon and other native fish. Without the Project in Reach 2B, restoration activities would be unlikely to achieve the Settlement goals.

Reach 2B Channel prior to Interim Flows

Project Study Area

The Project study area or "Project area" includes areas that may be affected directly or indirectly by the Project alternatives. The Project footprint (township 13S, range 15E), shown in Figure S-1, has two major components: Reach 2B and the Mendota Pool Bypass. Reach 2B generally includes the area from the San Joaquin River Control Structure near the Chowchilla Bypass downstream to Mendota Dam. Potential Project improvements in Reach 2B, which vary by alternative, extend from the Chowchilla Bifurcation Structure on the upstream end to the head of the potential Mendota Pool Bypass channel or to Mendota Dam on the downstream end. However, Reach 2B improvements may also include areas just upstream of the Chowchilla Bifurcation Structure and may continue downstream of the head of the Mendota Pool Bypass or Mendota Dam, including the Pool area, as necessary to meet Project goals and objectives. The lateral extent of potential Project Reach 2B improvements, which varies by alternative, includes lands to the north and south of the San Joaquin River in Reach 2B.

San Joaquin River near San Mateo Road

The Mendota Pool Bypass element of the Project alternatives generally includes the area from the downstream end of the Reach 2B improvements to a tie-in location in Reach 3. Improvements for the Mendota Pool Bypass, which vary by alternative, extend from the area south of Mowry Bridge over Fresno Slough to the area north of Mendota Dam where the bypass ties into Reach 3. The Mendota Pool Bypass element of the Project alternatives also includes areas adjacent to and on the west side of Mendota Pool and Fresno Slough and areas to the south of the potential Project Reach 2B improvements. Areas indirectly affected by this Project include portions of Reach 3 downstream and Reach 2A upstream that are outside the direct Project footprint.

The Project area reflects current estimates of areas that may be affected by the Project alternatives. In this EIS/R, the area where direct and indirect effects may occur differs according to resource area; therefore, the geographic range and environmental conditions described herein vary by resource.

Alternatives Evaluated in this EIS/R

This EIS/R presents a No-Action/No-Project Alternative (hereafter called the No-Action Alternative) and four Action Alternatives to implement the Project:

- No-Action Alternative
- Alternative A (Compact Bypass with Narrow Floodplain and South Canal)
- Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative
- Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)
- Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Each Action Alternative includes the actions called for in the Settlement for the Mendota Pool Bypass and Reach 2B. Action Alternatives would be designed to provide:

- Conveyance of at least 4,500 cfs in Reach 2B and through the Mendota Pool Bypass
- Diversion and screening of up to 2,500 cfs from Reach 2B into Mendota Pool

Of the four Action Alternatives, there are two methods of bypassing Restoration Flows around Mendota Pool, two floodplain widths, and four ways to divert water into Mendota Pool (Table S-1).

Reach 2B during Interim Flows

Table S-1. Additional Activities Common or Related to Action Alternatives

ACTIVITY	ACTION ALTERNATIVE			
	A	B	C	D
Constructing a **channel and structures** capable of conveying up to 4,500 cfs of Restoration Flows around the Mendota Pool	♦	♦		
Constructing a **dam** capable of containing Mendota Pool within Fresno Slough so that 4,500 cfs of Restoration Flows can be conveyed around the Mendota Pool			♦	♦
Restoring floodplain habitat an average of approximately 3,000 feet wide to provide benefit to salmonids and other native fishes	♦		♦	
Restoring floodplain habitat an average of approximately 4,200 feet wide to provide benefit to salmonids and other native fishes		♦		♦
Constructing the **South Canal and structures** capable of conveying up to 2,500 cfs from Reach 2B to Mendota Pool	♦			
Constructing the **Bifurcation structure** capable of conveying up to 2,500 cfs from Reach 2B to Mendota Pool		♦		
Constructing the **Short Canal and structures** capable of conveying up to 2,500 cfs from Reach 2B to Mendota Pool			♦	
Constructing the **North Canal and structures** capable of conveying up to 2,500 cfs from Reach 2B to Mendota Pool				♦
Building levees capable of conveying flows up to 4,500 cfs with 3 feet of freeboard	♦	♦	♦	♦
Providing upstream and downstream fish passage for adult salmonids and other native fishes, and downstream fish passage for juvenile salmonids, between Reach 2A and Reach 3	♦	♦	♦	♦

Key:

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)
Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure)
Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)
Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)
cfs = cubic feet per second

No-Action/No-Project Alternative

Under this alternative, the Project would not be implemented. The No-Action Alternative is not consistent with the Settlement.

Existing conditions were developed for each resource area based on the availability of historical data and recent observations. Future conditions were based on reasonably foreseeable actions that would occur without the Project. The conditions under the No-Action Alternative are the conditions that are predicted to exist in the Project area during the planning period if the Project is not implemented. If the Project were not implemented, the components described in the Action Alternatives would not be implemented; however, the No-Action Alternative assumes that other components of the SJRRP, as described in the 2012 Record of Decision, and other reasonably foreseeable actions consistent with current management direction expected to occur in the Project area, would be implemented.

California Kingsnake in Reach 2B

The No-Action Alternative generally assumes no channel or structural improvements would be made in Reach 2B, and Restoration Flows would be reduced to not exceed

the existing Reach 2B capacity. It is assumed for the No-Action condition that agriculture would continue, and cropland would be the dominant cover type, consistent with the existing condition.

Alternative A

Alternative A (Compact Bypass with Narrow Floodplain and South Canal) would construct a channel between Reach 2B and Reach 3, the Compact Bypass channel, in order to bypass the Mendota Pool. Restoration Flows would enter Reach 2B, flow through the reach, then downstream to Reach 3 via the Compact Bypass channel. A canal to convey San Joaquin River water deliveries to Mendota Pool, the South Canal, would be built. The San Joaquin River control structure at the Chowchilla Bifurcation Structure would be removed, and a bifurcation structure would be built at the head of the South Canal to control flood diversions into the Chowchilla Bypass and water delivery diversions into Mendota Pool. Fish passage facilities and a fish screen would be built at the South Canal bifurcation structure to provide passage around the structure and prevent fish being entrained in the diversion. A fish barrier would be built in Reach 3 to direct up-migrating fish into the Compact Bypass channel. A new crossing would be built at the San Mateo Avenue crossing. See Figure S-3 and Figure S-4 for a plan view of the alternative's features.

Leopard Frog in Reach 2B

Alternative B

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the preferred alternative, would construct a channel between Reach 2B and Reach 3, the Compact Bypass channel, in order to bypass the Mendota Pool. Restoration Flows would enter Reach 2B at the Chowchilla Bifurcation Structure, flow through Reach 2B, then downstream to Reach 3 via the Compact Bypass channel. The existing Chowchilla Bifurcation Structure would continue to divert San Joaquin River flows into the Chowchilla Bypass during flood operations, and a fish passage facility and control structure modifications would be included at the San Joaquin River control structure at the Chowchilla Bifurcation Structure. A bifurcation structure would be built at the head of the Compact Bypass channel to control diversions into Mendota Pool. Fish passage facilities would be built at the Compact Bypass bifurcation structure to provide passage around the structure. The existing San Mateo Avenue crossing would be removed. See Figure S-5 and Figure S-6 for a plan view of the alternative's features.

Alternative C

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal) would build a dam across Fresno Slough, the Fresno Slough Dam, to contain the Mendota Pool, and it would utilize the existing river channel in order to bypass the Mendota Pool. Restoration Flows would enter Reach 2B at the Chowchilla Bifurcation Structure, flow through Reach 2B, then downstream to Reach 3 over the sill at Mendota Dam. Mendota Pool would be contained south of the Fresno Slough Dam. The existing Chowchilla Bifurcation Structure would continue to divert San Joaquin River flows into the Chowchilla Bypass during flood operations, and a fish passage facility and control structure modifications would be included at the San Joaquin River control structure at the Chowchilla Bifurcation Structure. A canal to convey San Joaquin River water

deliveries to Mendota Pool, the Short Canal, would be built adjacent to the Fresno Slough Dam. The Mendota Dam along with a control structure built at the head of the Short Canal would be used to control diversions into Mendota Pool through the Short Canal. Fish passage facilities at Mendota Dam and a fish screen on the Short Canal would be built to provide passage around Mendota Dam and prevent fish from being entrained in the diversion. A fish barrier would be built downstream of the Fresno Slough Dam to keep up-migrating fish in Reach 2B. A new crossing would be built at the San Mateo Avenue crossing. See Figure S-7 and Figure S-8 for a plan view of the alternative's features.

Alternative D

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal) would build a dam across Fresno Slough, the Fresno Slough Dam, to contain the Mendota Pool, and it would utilize the existing river channel in order to bypass the Mendota Pool. Restoration Flows would enter Reach 2B, flow through the reach, then downstream to Reach 3 over the sill at Mendota Dam. Mendota Pool would be contained south of the Fresno Slough Dam. A canal to convey San Joaquin River water deliveries to Mendota Pool, the North Canal, would be built. The San Joaquin River control structure at the Chowchilla Bifurcation Structure would be removed, and a bifurcation structure would be built at the head of the North Canal to control flood diversions into the Chowchilla Bypass and water delivery diversions into Mendota Pool. Fish passage facilities and a fish screen would be built at the North Canal bifurcation structure to provide passage around the structure and prevent fish being entrained in the diversion. A fish barrier would be built downstream of the Fresno Slough Dam to keep up-migrating fish in Reach 2B. The existing San Mateo Avenue crossing would be removed. See Figure S-9 and Figure S-10 for a plan view of the alternative's features.

White-faced Ibis

Elements Common to All Action Alternatives

Some constructed elements are common to all Action Alternatives. Those elements are:

- Fish Habitat and Passage – One of the primary focuses of the Action Alternatives is to provide floodplain and riparian habitat to benefit migrating juvenile and adult salmonids and other native fishes. Floodplain and riparian habitats in the Action Alternatives would include a variety of native plant communities suited to the hydrology, soils, and climate of Reach 2B and the San Joaquin Valley. The Action Alternatives also include provision of fish passage at structures for salmonids and other native fish. These structures vary by alternative, but overall include fish screens, fish passage facilities, grade control structures, and bifurcation structures (under certain flows).
- Levees – Levees would be required along the Project area to contain Restoration Flows. While the height and footprint of the levees vary according to their locations along the channel and the ground elevation, the capacity, freeboard, and cross-section would be consistent. Localized backwater and redirection effects at Project structures would be considered during design of levee heights. Levees would be designed to maintain 3 feet of freeboard on the levees at 4,500 cfs. Levee alignments maintain a 300-foot buffer zone, where appropriate, between the levee and river channel to avoid impact to levees over time due to potential channel migration.

Chinook salmon

- Seepage Control Measures – Seepage of river water through or under levees is a concern for levee integrity and adjacent land uses. Through-seepage, water that seeps laterally through the levee section, would be addressed through proper levee design and construction (e.g., selection of low porosity materials and proper compaction). Under-seepage, water that seeps laterally by traveling under the levee section, is primarily controlled by the native soils beneath the levee, and seepage control measures would be included where native soils do not provide sufficient control.
- Borrow – Borrow material (suitable soils) would primarily be required for the construction of the levees, but it may also be used in the construction of other structures for foundation or backfill material. Levees may be constructed entirely of local borrow material, a mix of local and imported borrow material, or just imported borrow material.
- Levee and Structure Protection – Action Alternatives generally provide a minimum 300-foot buffer between the existing channel and the proposed levee, where appropriate and feasible. Locations that require erosion protection in the form of revetment include areas where the 300-foot buffer was not included due to the proximity of existing infrastructure, near the proposed structures, and along river bends less than 300 feet from the levee.

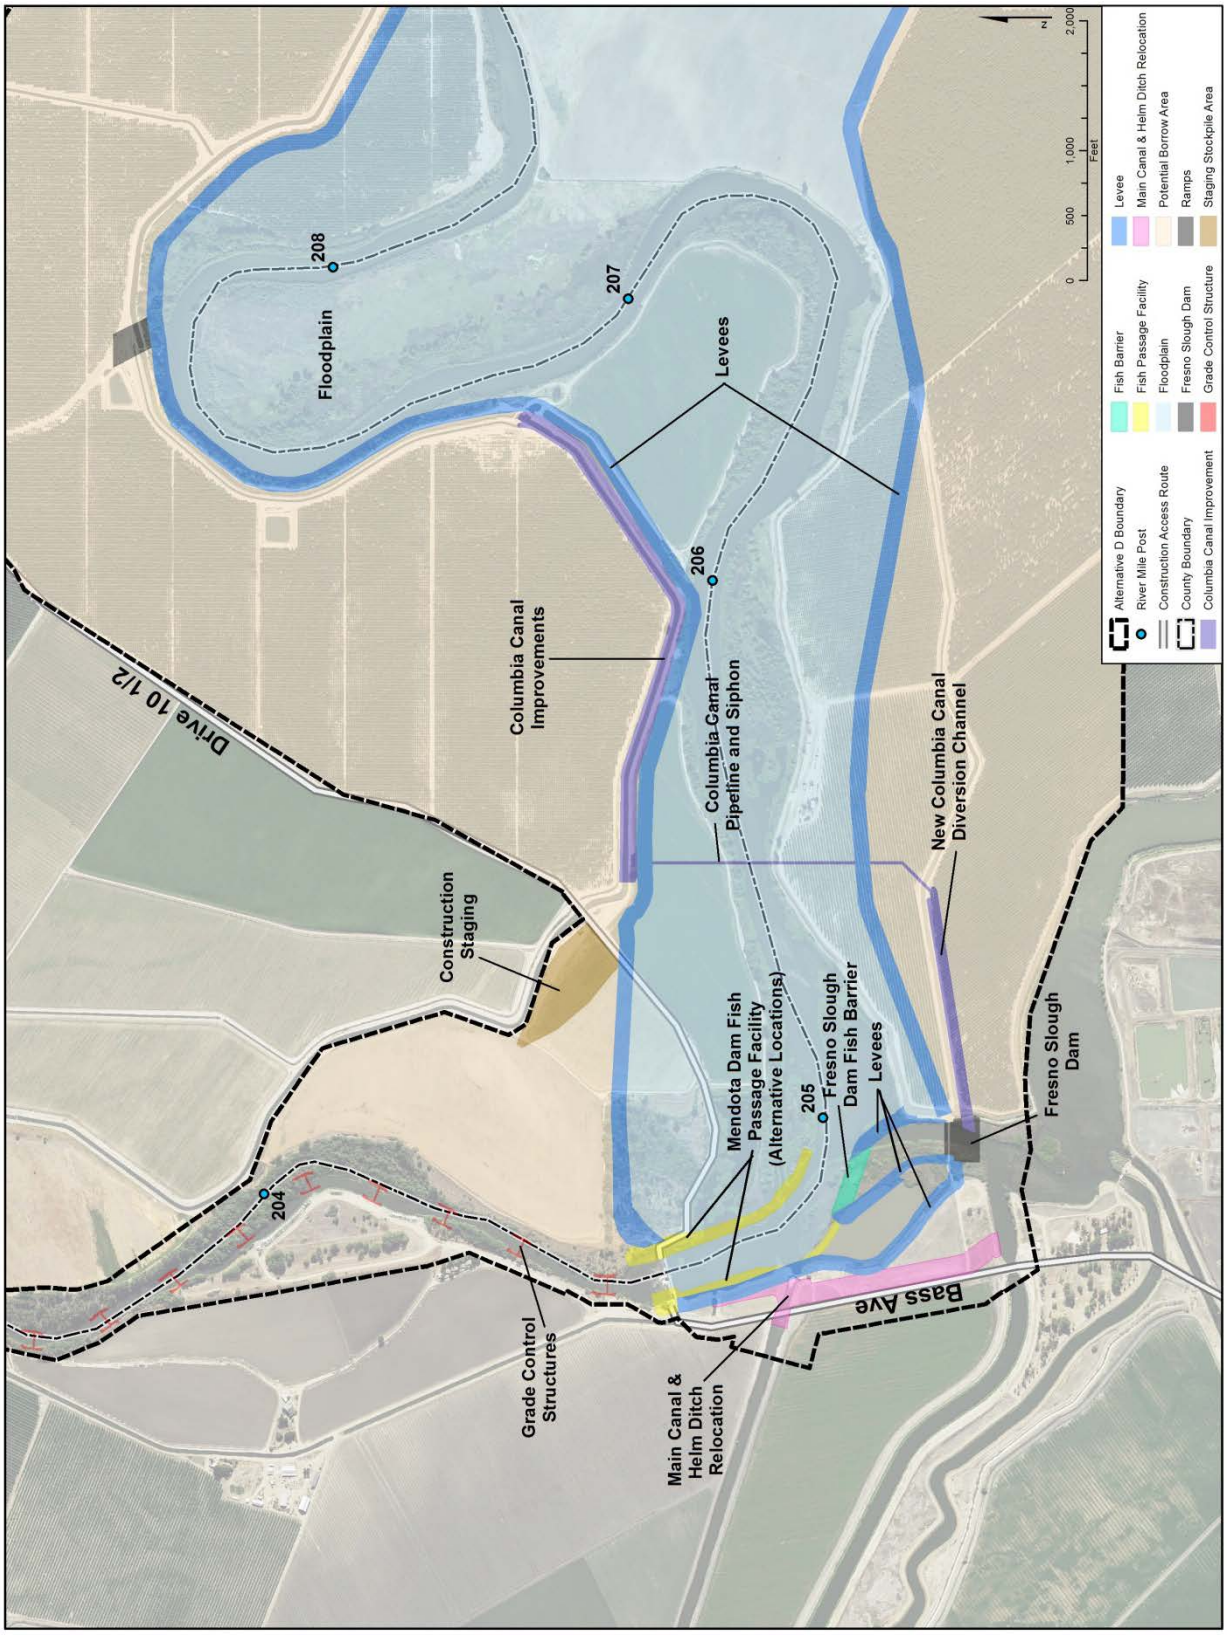
Figure S-10. Inset Map of Alternative D
(Fresno Slough Dam with Wide Floodplain and North Canal)



- Removal of Existing Levees – Removal of portions of the existing levees is included and designed to expand the inundation area of the floodplain out to the proposed levees and improve connectivity between the river channel and proposed floodplain. The locations of existing levee removal would be based upon the hydraulic performance of the channel and floodplain. In certain locations, however, highly desirable existing vegetation (native and sensitive vegetation communities that can serve as seed banks for future vegetation communities) can be found on the existing levees. Where hydraulic performance and connectivity of the floodplain would not be negatively affected, portions of the existing levees with highly desirable vegetation would remain in place.
- Floodplain Grading – Floodplain and channel grading can provide benefits to salmon and other native fish by allowing inundation to occur at lower flows, by distributing suitable rearing habitats further into the floodplain, by connecting rearing habitat to primary production areas (shallow water habitat), by providing escape routes during receding flows, and by confining flows to a deeper, narrower channel to limit temperature increases.
- Infrastructure for Fish Monitoring – The designs for control structures, fish passage facilities, and fish screens include security fences and gates, mounting hardware, and electrical supply in order to conduct fish monitoring activities. The fish monitoring activities themselves are not included in this Project, and will be addressed in subsequent environmental analysis, as appropriate.
- Existing Infrastructure Relocations or Floodproofing – Existing infrastructure such as groundwater wells, pumps, electrical and gas distribution lines, water pipelines, and canals is located in the Project area and would require relocation or floodproofing to protect them from future Restoration Flows and increased floodplain area.
- Construction Access – Access for vehicles carrying materials, equipment, and personnel to and from the construction area would be provided via several existing roadways in the Project vicinity. Improvements may be required to upgrade roadways, pavements, and crossings for anticipated construction traffic and loads, provide adequate turning radii and site distances, and to control dust on non-paved roads.
- Revegetation of Temporary Disturbance Areas – Areas temporarily disturbed during construction would be restored to their previous contours, if feasible, and then seeded with a native vegetation seed mixture to prevent soil erosion. Some areas, such as borrow areas, may not be feasible to restore previous contours, but these areas would be smoothed and seeded.
- Land Acquisition – Additional lands would be acquired to accommodate the floodplain, levees, bypass channel, structures, and borrow. The amount of land acquisition varies with alternative.
- Phased Implementation – The Project may utilize a phased approach to implementation of the selected alternative. Phased implementation would involve building selected components of the Project in separate construction phases, allowing Project funding to be secured over time.

Reach 2B Riparian Corridor

In addition to these elements, the following activities are also common to all Action Alternatives:

- Operations and Maintenance – The Project includes long-term operations and maintenance of the proposed facilities and features.
- Monitoring Activities – Monitoring activities in Reach 2B could include flow monitoring, groundwater level monitoring, aerial and topographic surveys, vegetation surveys, sediment mobilization and monitoring, and passage and screen effectiveness.

Field Surveys in Reach 2B

Vegetation Surveys in Reach 2B

Environmental Commitments

Conservation Strategy

As part of SJRRP implementation, a comprehensive strategy for the conservation of listed and sensitive species and habitats has been prepared, and will be implemented in coordination with USFWS, NMFS, and DFW. The goals of the strategy are as follows:

- Conserve riparian vegetation and waters of the United States, including wetlands
- Control and manage invasive species
- Conserve special-status species

The SJRRP's Conservation Strategy includes conservation measures for biological resources that may be affected by Project actions (listed in Table S-2). These measures are the same as those presented in the PEIS/R (SJRRP 2011a, pages 2-55 to 2-79) and those detailed in Section 2.2.10 of this EIS/R.

Elderberry in Reach 2B

Table S-2. Conservation Measures for Biological Resources

IDENTIFIER	CONSERVATION MEASURE
VELB	**VALLEY ELDERBERRY LONGHORN BEETLE**
VELB-1	Avoid and minimize effects to species
VELB -2	Compensate for temporary or permanent loss of habitat
BNLL	**BLUNT-NOSED LEOPARD LIZARD**
BNLL-1	Avoid and minimize effects to species
BNLL-2	Compensate for temporary or permanent loss of habitat or species
PLANTS	**OTHER SPECIAL-STATUS PLANTS**
PLANTS-1	Avoid and minimize effects to special-status plants
GGS	**GIANT GARTER SNAKE**
GGS-1	Avoid and minimize loss of habitat for giant garter snake
GGS-2	Compensate for temporary or permanent loss of habitat
WPT	**WESTERN POND TURTLE**
WPT-1	Avoid and minimize loss of individuals
EAGLE	**BALD EAGLE AND GOLDEN EAGLE**
EAGLE-1	Avoid and minimize effects to bald and golden eagles (as defined in the Bald and Golden Eagle Protection Act)
SWH	**SWAINSON'S HAWK**
SWH-1	Avoid and minimize impacts to Swainson's Hawk
SWH-2	Compensate for loss of nest trees and foraging habitat
RAPTOR	**OTHER NESTING RAPTORS**
RAPTOR-1	Avoid and minimize loss of individual raptors
RAPTOR-2	Compensate for loss of nest trees
RNB	**RIPARIAN NESTING BIRDS: LEAST BELL'S VIREO**
RNB-1	Avoid effects to species
RNB-2	Avoid, minimize, and compensate for effects to species
MBTA	**OTHER BIRDS PROTECTED BY THE MIGRATORY BIRD TREATY ACT**
MBTA-1	Avoid and minimize effects to species
BRO	**BURROWING OWL**
BRO-1	Avoid loss of species
BRO-2	Minimize impacts to species
BAT	**SPECIAL-STATUS BATS**
BAT-1	Avoid and minimize loss of species
BAT-2	Compensate for loss of habitat
FKR	**FRESNO KANGAROO RAT**
FKR-1	Avoid and minimize effects to species
FKR-3	Compensate for temporary or permanent loss of habitat or species
SJKF	**SAN JOAQUIN KIT FOX**
SJKF-1	Avoid and minimize effects to species
PL	**PACIFIC LAMPREY**
PL-1	Avoid and minimize effects to species
RHSNC	**RIPARIAN HABITAT AND OTHER SENSITIVE NATURAL COMMUNITIES**
RHSNC-1	Avoid and minimize loss of riparian habitat and other sensitive natural communities
RHSNC-2	Compensate for loss of riparian habitat and other sensitive natural communities

Table S-2. Conservation Measures for Biological Resources

IDENTIFIER	CONSERVATION MEASURE
WUS	**WATERS OF THE UNITED STATES/WATERS OF THE STATE**
WUS-1	Identify and quantify wetlands and other waters of the United States
WUS-2	Obtain permits and compensate for any loss of wetlands and other waters of the United States/waters of the State
INV	**INVASIVE PLANTS**
INV-1	Implement the Invasive Vegetation Monitoring and Management Plan
CP	**CONSERVATION PLANS**
CP-1	Remain consistent with approved conservation plans
CP-2	Compensate effects consistent with approved conservation plans
GS	**SOUTHERN DISTINCT POPULATION SEGMENT OF NORTH AMERICAN GREEN STURGEON**
GS-1	Avoid and minimize loss of habitat and individuals
CVS	**CENTRAL VALLEY STEELHEAD**
CVS-1	Avoid loss of habitat and risk of take of species
CVS-2	Minimize loss of habitat and risk of take of species
SRCS	**CENTRAL VALLEY SPRING-RUN CHINOOK SALMON**
SRCS-1	Avoid and minimize loss of habitat and individuals
EFH	**ESSENTIAL FISH HABITAT (PACIFIC SALMONIDS AND STARRY FLOUNDER)**
EFH-1	Avoid loss of habitat and risk of take of species
EFH-2	Minimize loss of habitat and risk of take from implementation of construction activities

Ash-throated Flycatcher in Reach 2B

Minimize Flood Risk from Interim and Restoration Flows

The SJRRP's strategy for minimizing flood risk is to limit the maximum downstream extent and rate of Interim and Restoration flows for the given reach to then-existing channel capacities. This strategy is incorporated by reference from the PEIS/R (SJRRP 2011a, pages 2-22 through 2-28) and summarized in Section 2.2.10 of this EIS/R. These Program-wide commitments are documented in the PEIS/R Record of Decision (ROD), and no new Project-level actions to minimize flood risk from Interim and Restoration flows are being proposed.

Reach 2B during Interim Flows

Areas of Known Controversy and Issues to be Resolved

State CEQA Guidelines section 15123, subdivision (b), requires that an Executive Summary identify "areas of controversy known to the lead agency including issues raised by agencies and the public." The alternatives development process provided opportunities for early stakeholder involvement and input. Primary stakeholders include Federal, State, and local agencies, landowners, the Restoration Administrator and Technical Advisory Committee of the SJRRP, non-governmental organizations, and the public. Comments received during the scoping process include topics related to agriculture, air quality, canal distribution systems, economic development, flood control and levees, groundwater and wells, wells, Interim Flows, surface water, traffic, water quality, wetland and riparian environment, SJRRP actions, and the construction schedule. Areas of known controversy include the potential for groundwater seepage to occur in agricultural areas outside of the floodplain, the potential for future long-term recreational development of the Project area, and the need for a Mendota Pool Fish Screen and Reach 3 Fish Barrier. Groundwater seepage will be addressed during levee design and through the SJRRP's seepage management activities, which are being analyzed in separate environmental analysis, as appropriate (potential groundwater impacts of the Project are analyzed and disclosed in this EIS/R and mitigation measures are discussed as appropriate). Although recreational development is not within the scope of the Project, portage facilities around Project structures would include signage regarding safety and trespass issues. The Mendota Pool Fish Screen and Reach 3 Fish Barrier are analyzed in the Project alternatives; The Record of Decision for this Project will describe the project elements that Reclamation intends to implement as the selected alternative for the Project. There are no remaining issues to be resolved.

Red-tailed Hawk in Reach 2B

Consensus-Based Alternative Selection

A meeting was held on January 29, 2013, in order to introduce the consensus-based alternative concept and approach to the adjacent landowners, canal companies, irrigation districts, levee districts, cities, and the Settling Parties. The consensus-based alternative approach gave these entities the opportunity to provide input on the Project alternatives, and their input was considered during the identification of the preferred alternative. Following several meetings with the individuals and groups listed above, Reclamation and CSLC identified a preferred alternative, Alternative B, based on the input received on the Action Alternatives. The preferred alternative identified in this EIS/R is preliminary, and a final alternative will not be selected for implementation until consideration of comments received on the public draft EIS/R. The alternative selected for implementation will be articulated in the Record of Decision, which will be completed no less than 30 days following the release of the final EIS/R, and in the findings and other documents completed in accordance with CEQA.

Orchard in bloom in the San Joaquin Valley

Summary and Comparison of Impacts and Mitigation Measures

The impact conclusions and associated mitigation measures for the 21 resource topics evaluated in this EIS/R are summarized Tables S-3 and S-4. Impacts with the potential to result in a cumulatively considerable contribution to a significant cumulative impact are shown in Table S-5. Most action alternatives have the same impact level of significance before and after mitigation. For these impacts, Table S-3 below compares the No-Action alternative to the Action Alternatives together.

Table S-5. Impacts of Action Alternatives with the Potential to Result in a Cumulatively Considerable Incremental Contribution to a Significant Cumulative Impact

RESOURCE AREA	IMPACT
Air Quality	Exposure of sensitive receptors to Project inputs and additional industrial sources, construction projects, and vehicles on roadways in the Project area.
Cultural Resources	Disturbance or Destruction of Cultural Resources
Environmental Justice	Regional economic factors that are adversely affecting minority and/or low-income populations
Land Use Planning and Agriculture	Conversion of designated Farmland to nonagricultural uses
Socioeconomics and Economics	Substantial short term economic impacts associated with losses in agricultural production
Transportation and Traffic	Temporary or permanent road closure(s) that could affect emergency access or emergency response times

SAN JOAQUIN RIVER
RESTORATION PROGRAM

1.0 Introduction

This Environmental Impact Statement/Report (EIS/R) documents the assessment of environmental effects of the implementation of the Mendota Pool Bypass and Reach 2B Improvements Project (Project), a component of Phase 1 of the overall San Joaquin River Restoration Program (SJRRP). The SJRRP was established in late 2006 to implement the Stipulation of Settlement (Settlement) in *Natural Resources Defense Council (NRDC), et al., v. Kirk Rodgers, et al*.

The U.S. Department of the Interior, Bureau of Reclamation (Reclamation), as the Federal lead agency under the National Environmental Policy Act (NEPA), and the California State Lands Commission (CSLC), as the State of California (State) lead agency under the California Environmental Quality Act (CEQA), prepared this EIS/R for the Project. Federal authorization for implementing the Settlement is provided in the San Joaquin River Restoration Settlement Act (Act) (Public Law 111-11).

1.1 Background

Originating high in the Sierra Nevada Mountains, the San Joaquin River carries snowmelt from mountain meadows to the valley floor before turning north and becoming the backbone of tributaries draining into the San Joaquin Valley. The San Joaquin River is California's second longest river and discharges to the Sacramento-San Joaquin Delta (Delta) and, ultimately, to the Pacific Ocean through San Francisco Bay.

Historically, the San Joaquin River supported a rich and diverse ecosystem influenced by seasonal runoff patterns. During winter and spring months, runoff from Sierra Nevada streams would spread over the valley floor and slowly drain to the Delta, providing rich habitat supporting numerous aquatic and wildlife species, including Chinook salmon.

Over the past two centuries, development of water resources transformed the San Joaquin River. In the late 1880s, settlers in the Central Valley drained large areas of valley floor lands and put these lands into agricultural production, supported by small and seasonal diversion dams on the river and a series of water conveyance and drainage canals. Hydroelectric project development in the upper portions of the San Joaquin River watershed harnessed power from the river and modified the natural flow patterns.

In 1942, Reclamation completed construction of Friant Dam on the San Joaquin River. With the completion of Madera Canal in 1945 and Friant-Kern Canal in 1951, Friant Dam diverted San Joaquin River water supplies to over 1 million acres of highly productive farmland along the eastern portion of the San Joaquin Valley. Operation of the dam ceased flow in some portions of the river and contributed to the extirpation of salmon runs in the San Joaquin River upstream from the confluence with the Merced River.

1.1.1 Stipulation of Settlement

In 1988, a coalition of environmental groups, led by the Natural Resources Defense Council (NRDC) filed a lawsuit, known as *NRDC, et al., v. Kirk Rodgers, et al.*, challenging the renewal of long-term water service contracts between the United States and the Central Valley Project (CVP) Friant Division contractors. On September 13, 2006, after more than 18 years of litigation, the Settling Parties, including NRDC, Friant Water Authority (FWA), and the U.S. Departments of the Interior and Commerce, agreed on the terms and conditions of a Settlement subsequently approved by the U.S. Eastern District Court of California (Court) on October 23, 2006. Public Law 111-11, signed on March 30, 2009, authorizes and directs the Secretary of the Interior (Secretary) to implement the Settlement. The Settlement establishes two primary goals:

- **Restoration Goal** – To restore and maintain fish populations in "good condition" in the main stem San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally reproducing and self-sustaining populations of salmon and other fish.
- **Water Management Goal** – To reduce or avoid adverse water supply impacts on all of the Friant Division long-term contractors that may result from the Interim and Restoration flows provided for in the Settlement.

To achieve the Restoration Goal, the Settlement calls for releases of water from Friant Dam to the confluence of the Merced River (referred to as Interim and Restoration flows), a combination of channel and structural modifications along the San Joaquin River below Friant Dam, and reintroduction of Chinook salmon. Restoration Flows are specific volumes of water to be released from Friant Dam during different water year types, according to Exhibit B of the Settlement and began on January 1, 2014; Interim Flows were experimental flows that began in 2009 and continued until Restoration Flows were initiated, with the purpose of collecting relevant data concerning flows, temperatures, fish needs, seepage losses, recirculation, recapture, and reuse.

To achieve the Water Management Goal, the Settlement calls for recirculation, recapture, reuse, exchange or transfer of the Interim and Restoration flows to reduce or avoid impacts to water deliveries to all of the Friant Division long-term contractors caused by the Interim and Restoration flows. In addition, the Settlement establishes a Recovered Water Account (RWA) and program to make water available to all of the Friant Division long-term contractors who provide water to meet Interim or Restoration flows to reduce or avoid the impact of the Interim and Restoration flows on such contractors.

The Settlement and the Act authorize and direct specific physical and operational actions that could potentially directly or indirectly affect environmental conditions in the Central Valley. Areas potentially affected by Settlement actions include the San Joaquin River and associated flood bypass system, tributaries to the San Joaquin River, the Delta, and water service areas of the CVP and State Water Project (SWP), including the Friant Division. Settlement Paragraphs 11 through 16 describe physical and operational actions (see Table 1-1).

Table 1-1.
Restoration and Water Management Framework in Key Settlement Paragraphs

Settlement Paragraph	Description of Constraint or Assumption
11	Identifies specific channel and structural improvements considered necessary to achieve the Restoration Goal. Includes a reach-by-reach list of improvements.
12	Acknowledges that additional channel or structural improvements not identified in Paragraph 11 may be needed to achieve the Restoration Goal.
13	Identifies specific volumes of water to be released from Friant Dam during different year-types (Restoration Flows), and provisional water supplies to meet the Restoration Flow targets as provided in Exhibit B of the Settlement. Stipulates the release of Restoration Flows no later than January 1, 2014, subject to then-existing channel capacities.
14	Stipulates that spring-run and fall-run Chinook salmon be reintroduced to the San Joaquin River between Friant Dam and the confluence of the San Joaquin River with the Merced River no later than December 31, 2012, consistent with all applicable law and after commencement of sufficient flows and the issuance of all necessary permits. Assigns priority to wild spring-run Chinook salmon over fall-run Chinook salmon.
15	Specifies that Interim Flows begin no later than October 1, 2009, and continue until Restoration Flows can begin, to collect relevant data concerning flows, temperatures, fish needs, seepage losses, recirculation, recapture, and reuse.
16	Requires that the Secretary of the Interior develop and implement a plan for recirculation, recapture, reuse, exchange, or transfer of the Interim and Restoration flows to reduce or avoid impacts to water deliveries for all Friant Division long-term contractors. This paragraph also calls for establishment of an RWA and program to make water available to the Friant Division long-term contractors who provide water to meet Interim or Restoration flows.

Key:
RWA = Recovered Water Account

1.1.2 San Joaquin River Restoration Program

The SJRRP comprises several Federal and State agencies responsible for implementing the Settlement. Implementing Agencies include: Reclamation, U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NMFS), California Department of Water Resources (DWR), and California Department of Fish and Wildlife (DFW). In addition, the Settlement stipulates that a Technical Advisory Committee be established, comprising six members appointed by NRDC and FWA. The Settlement also calls for a Restoration Administrator (RA) to be appointed by NRDC and FWA, to facilitate the Technical Advisory Committee and provide specific recommendations to the Secretary in coordination with the Technical Advisory Committee. The RA's duties are defined in the Settlement, and include making recommendations to the Secretary on the release of Interim and Restoration flows. The RA is also responsible for consulting with the Secretary on implementing actions under Paragraph 11 of the Settlement, and for identifying and recommending additional actions under Paragraph 12 of the Settlement. In addition, the RA is responsible for consulting with the Secretary on the reintroduction of Chinook salmon under Paragraph 14 of the Settlement and flow releases under Paragraphs 13 and 15. The Secretary will diligently pursue completion of project-specific actions in consultation with the RA.

Exhibit C of the Settlement sets forth milestone dates for the purposes of implementing the Settlement. The Implementing Agencies acknowledge that some of the implementation, including this project, is unavoidably behind schedule and have developed a Draft Framework for Implementation with a revised schedule (SJRRP 2015).

1.1.3 Overview of the Mendota Pool Bypass and Reach 2B Improvements

The Project includes the construction, operation, and maintenance of the Mendota Pool Bypass and improvements in the San Joaquin River channel in Reach 2B (Figure 1-1). The Project consists of a floodplain width which conveys at least 4,500 cubic feet per second (cfs), a method to bypass Restoration Flows around Mendota Pool, and a method to deliver water to Mendota Pool. The Project footprint (Figure 1-2) extends from approximately 0.3 mile above the Chowchilla Bifurcation Structure to approximately 1.7 miles below the Mendota Dam. The Project footprint comprises the area that could be directly affected by the Project. The Project may also indirectly affect nearby portions of Reach 2A and Reach 3. The Project study area or "Project area" includes areas directly and indirectly affected by the Project. The Project area is in Fresno and Madera counties, near the town of Mendota, California.

The Mendota Pool Bypass and Reach 2B improvements defined in the Settlement are (Settlement Paragraph 11[a]):

> *(1) Creation of a bypass channel around Mendota Pool to ensure conveyance of at least 4,500 cfs from Reach 2B downstream to Reach 3. This improvement requires construction of a structure capable of directing flow down the bypass and allowing the Secretary to make deliveries of San Joaquin River water into Mendota Pool when necessary;*
>
> *(2) Modifications in channel capacity (incorporating new floodplain and related riparian habitat) to ensure conveyance of at least 4,500 cfs in Reach 2B between the Chowchilla Bifurcation Structure and the new Mendota Pool bypass channel.*

Because the functions of these channels may be inter-related, the design, environmental compliance, and construction of the two are being addressed as one project. The Project would be implemented consistent with the Settlement and the Act, with implementation dates clarified by the Implementation Framework (SJRRP 2015).

The Mendota Pool Bypass would include conveyance of at least 4,500 cfs around Mendota Pool (or the Pool) from Reach 2B to Reach 3 and a fish barrier, if appropriate, to direct upmigrating adult salmon into the bypass. The bypass could be accomplished by constructing a new channel around Mendota Pool or by limiting Mendota Pool to areas outside of the San Joaquin River. This action would include the ability to divert 2,500 cfs to the Pool if water deliveries are required for the San Joaquin River Exchange Contractors (Exchange Contractors) and may consist of a bifurcation structure in Reach 2B. The bifurcation structure would include a fish passage facility to enable up-migrating salmon to pass the structure and a fish screen, if appropriate, to direct out-migrating fish into the bypass channel and minimize or avoid fish entrainment to the Pool.

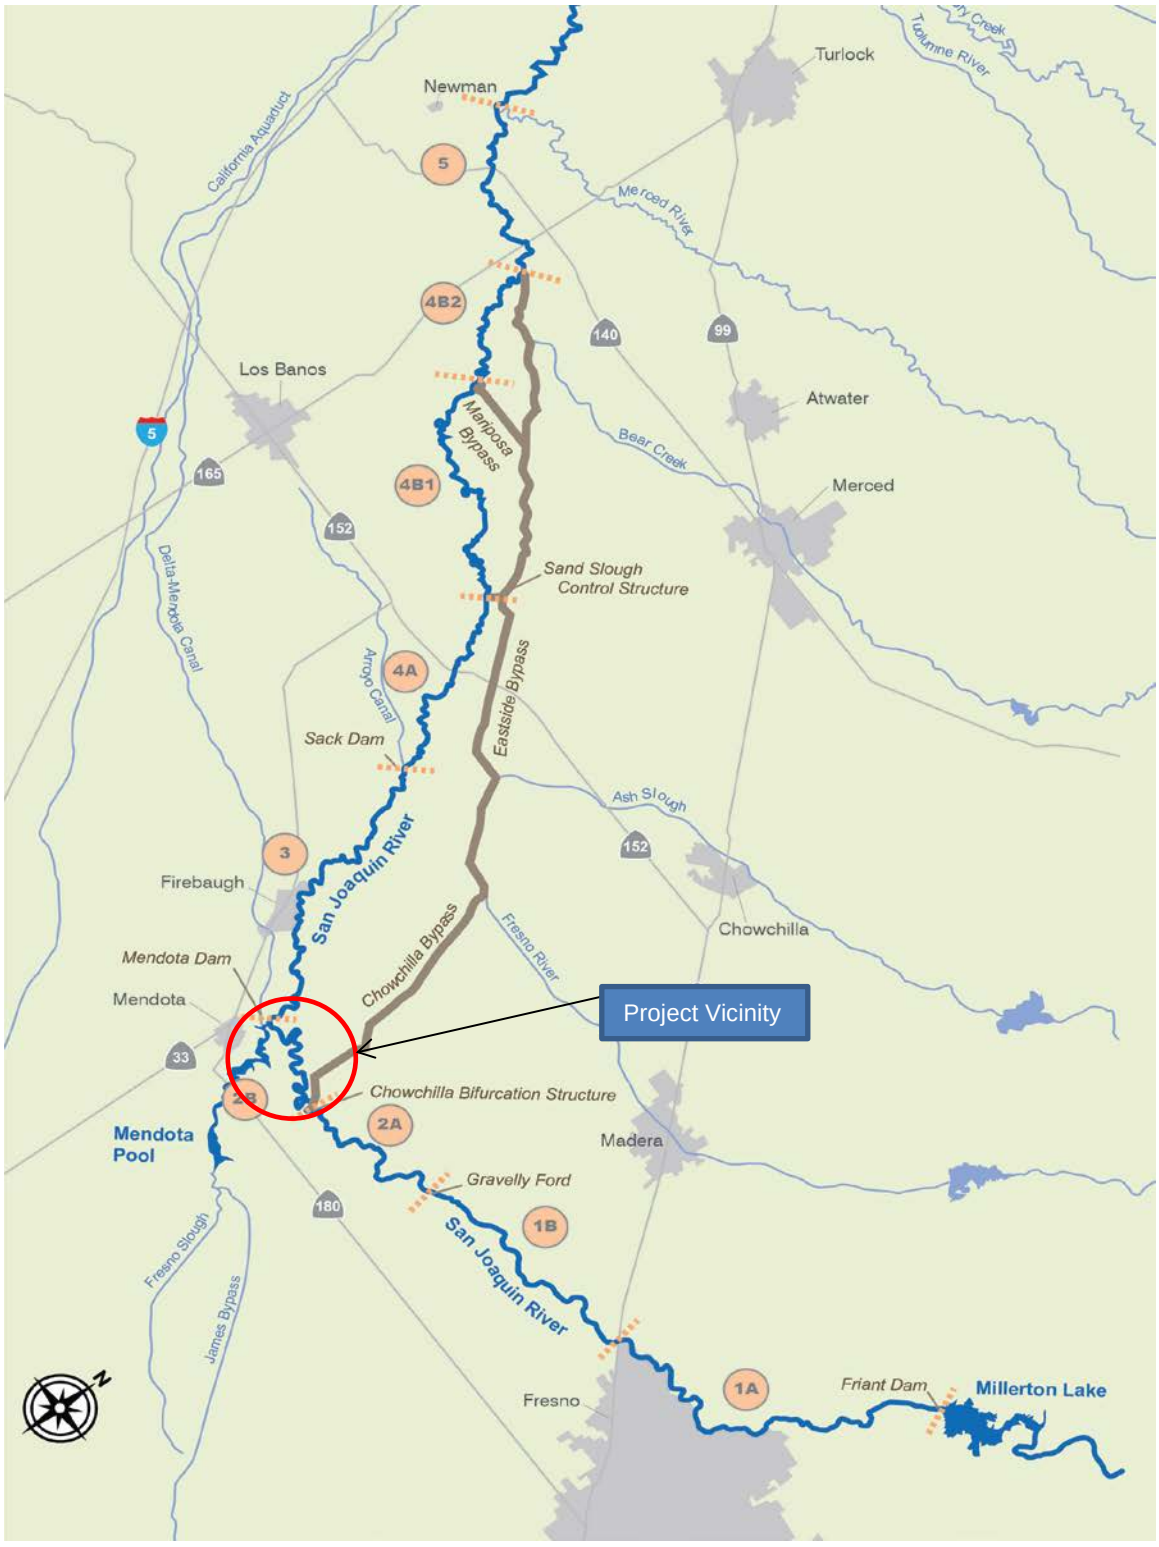

Figure 1-1.
Overview of the SJRRP Restoration Area and the Project Vicinity

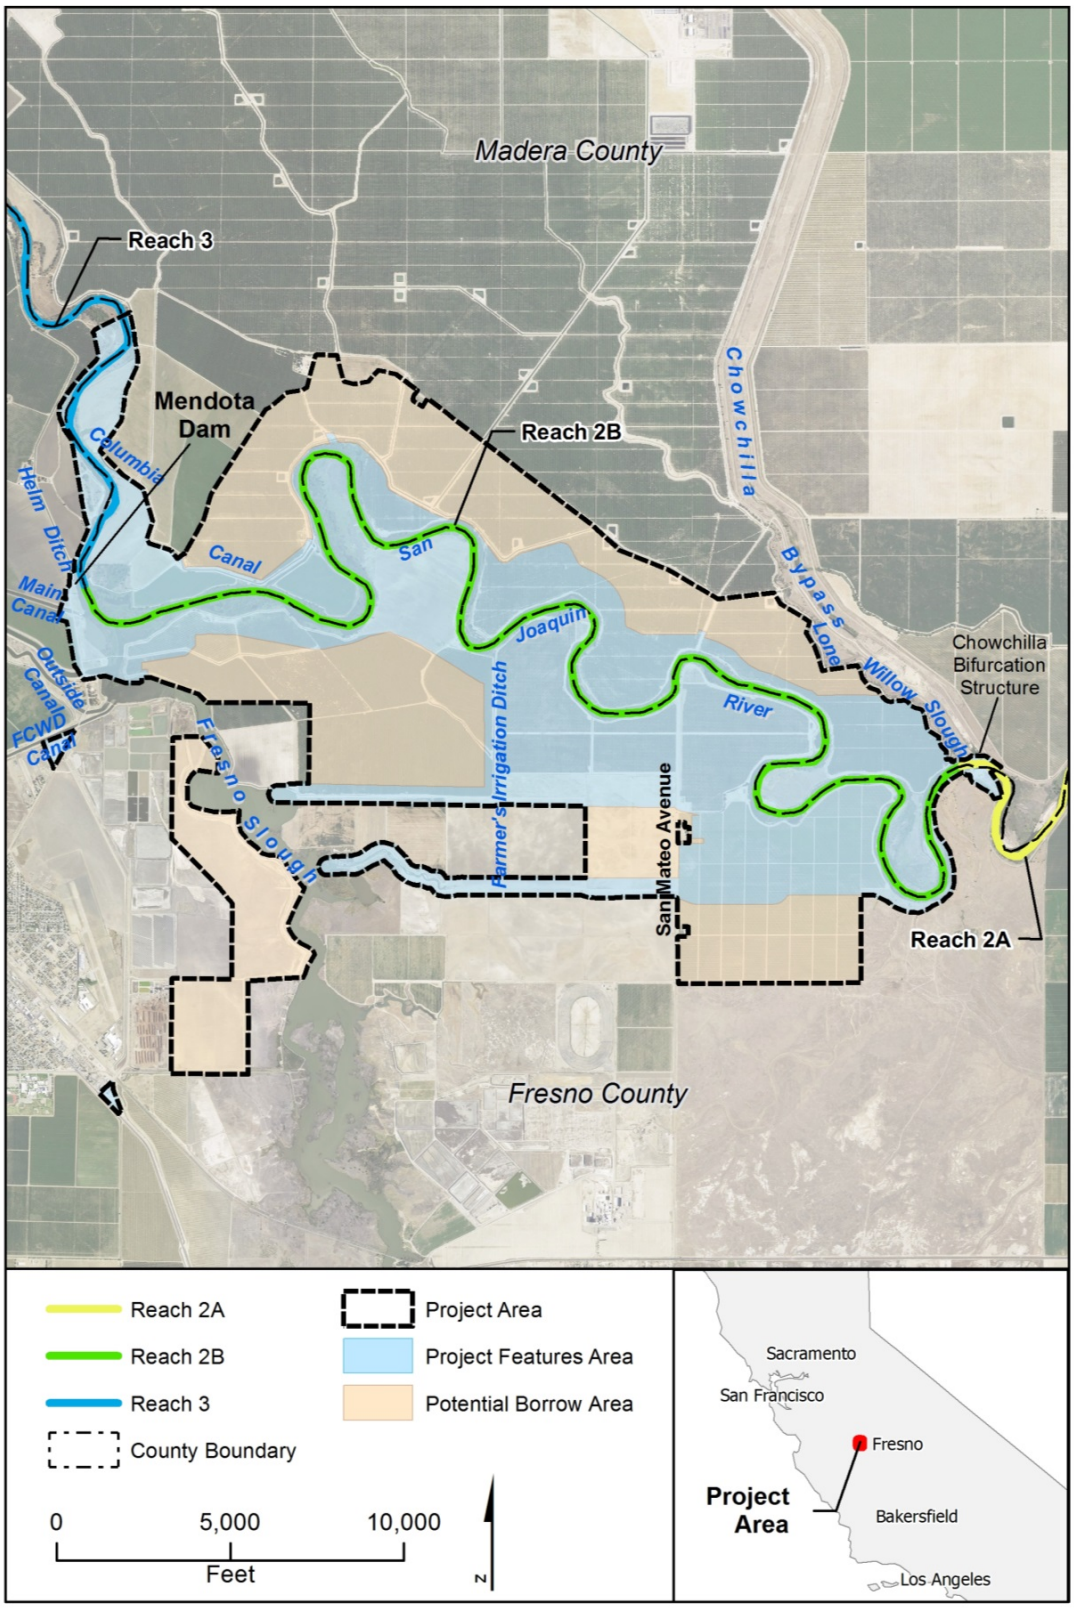

Figure 1-2.
Project Footprint and Vicinity

Improvements to Reach 2B would include modifications to the San Joaquin River channel from the Chowchilla Bifurcation Structure to the new Mendota Pool Bypass to provide a capacity of at least 4,500 cfs with integrated floodplain habitat. The options under consideration include potential levee setbacks along Reach 2B to increase the channel and floodplain capacity and provide for floodplain habitat. Floodplain habitat is included along the Reach 2B portion of the Project as required by the Settlement; floodplain habitat is being considered along the Mendota Pool Bypass channel because Central Valley floodplains have been shown to be of value to rearing juvenile salmon as they migrate downstream (Jeffres 2008, Grosholz 2006, Sommer 2004, Sommer 2001). In addition, the SJRRP *Fisheries Management Plan* (SJRRP 2010a) and *Minimum Floodplain Habitat Area for Spring and Fall-Run Chinook Salmon* report (SJRRP 2012a) describe that sufficient floodplain habitat is an important feature for meeting salmon population targets.

Improvements included in the project could potentially be implemented in a phased approach to facilitate scheduling and funding. Phased implementation is discussed further in Section 2.2.4.

1.1.4 Scoping and Public Involvement Process

The lead agencies conducted public and stakeholder outreach activities to engage and inform all interested parties of Project activities. Engaging those interested parties helped to inform the process for scoping the Project alternatives and development of this EIS/R. Reclamation initiated the NEPA process by issuing a Notice of Intent (NOI) on July 13, 2009, and DWR initiated the CEQA process by issuing a Notice of Preparation (NOP) on the same day, to prepare an EIS/R and hold public scoping meetings. (Although initial CEQA actions were conducted by DWR, subsequent actions during the EIS/R process have been conducted by the CSLC as the State lead agency.)

The EIS/R scoping comment period began the date the NOI was issued and ended on August 14, 2009. The Implementing Agencies convened two public meetings, one each in Fresno (July 28, 2009) and Firebaugh (July 29, 2009), to inform the public and interested stakeholders about the Project, and to solicit comments and input on the scope of the EIS/R. Reclamation and DWR received comments from 29 entities, including Federal and State agencies, local interest groups, local residents, farmers, landowners, public advocacy groups, and individuals. The comments received were summarized in a Public Scoping Report released February 2010 (SJRRP 2010b). The NEPA scoping process also serves as the scoping process for compliance with other Federal laws such as the National Historic Preservation Act, Section 106.

Public involvement and outreach activities have enabled the Implementing Agencies to involve stakeholders and incorporate public and stakeholder input into the development of major Project documents, including this EIS/R. These activities seek to create an open and transparent process through which the general public, stakeholders, affected Third Parties, and other interested parties can track and participate in SJRRP activities, including the formulation of alternatives for this EIS/R. Ongoing public outreach activities conducted in support of the Project include the following:

- Hosting Project-specific landowner meetings as well as participating in SJRRP Technical Feedback Meetings with subject-matter experts, Settling Parties, affected stakeholders, and the general public to obtain information and viewpoints from individual attendees; provide updates on the status of Project work products; keep the Technical Feedback Group up-to-date with the current status of the Project; gather feedback on Project documents; and discuss potential opportunities and constraints that may arise. The format of obtaining and disseminating information through the landowner meetings and Technical Feedback Group meetings is intended to be flexible to address the issues and documents at hand and to accommodate the needs of the SJRRP, Settling Parties, stakeholders, and the general public.
- Making available technical memoranda and other milestone Project documents to the general public, stakeholders, affected Third Parties, and other interested parties on the SJRRP website.

The lead agency must, whenever practicable, use a consensus-based management approach to the NEPA process, as required by 43 Code of Federal Regulations (CFR) 46.110. Consensus-based management "involves outreach to persons, organizations or communities who may be interested in or affected by a proposed action with an assurance that their input will be given consideration by the Responsible Official in selecting a course of action" (43 CFR 46.110 (a)). This EIS/R was developed with a consensus-based management approach. The completed and ongoing activities conducted in support of the Project, as described above, constitute outreach performed in support of this approach.

1.2 Purpose and Uses of this EIS/R

The purpose of this EIS/R is to analyze the project-specific direct, indirect, and short-term/long-term impacts of implementing the Project as directed by the Act, consistent with NEPA/CEQA requirements. This EIS/R serves as an informational document for decision makers, public agencies, non-government organizations, and the general public regarding the potential direct and indirect environmental consequences of implementing any of the alternatives. Consistent with CEQ Regulations, 40 CFR Part 46.425, and State CEQA Guidelines, Alternative B has been identified as the preferred alternative. No sooner than 30 days after the Final EIS/R is published, Reclamation will prepare a Record of Decision (ROD). Similarly, CSLC will take actions on whether to certify the EIR, approve a project, and file a Notice of Determination (NOD).

1.2.1 National Environmental Policy Act

NEPA provides an interdisciplinary framework for Federal agencies to take environmental factors into account during a decision making process (42 United States Code [USC] 4321, 40 CFR 1500.1). NEPA requires an Environmental Impact Statement (EIS) whenever a proposed major Federal action (e.g., a proposal for legislation or an activity financed, assisted, conducted, or approved by a Federal agency with Federal agency control) significantly affects the quality of the human environment. Section

1508.14 of the CEQ Regulations defines the human environment to include "the natural and physical environment and the relationship of people with that environment."

The EIS, in conjunction with other relevant material, is used by the Federal Government to plan actions and make decisions. Section 1502.1 of the CEQ Regulations states that the primary purpose of an EIS is to serve as an action-forcing device to insure that the policies and goals defined in NEPA are infused into the ongoing programs and actions of the Federal Government. As an informational document, an EIS provides a rigorous and objective evaluation of all reasonable alternatives; full and open disclosure of environmental consequences before agency action; an interdisciplinary approach to project evaluation; identification of measures to mitigate impacts; and an avenue for public and agency participation in decision making. NEPA defines mitigation as avoiding, minimizing, rectifying, reducing or eliminating, or compensating for an action (40 CFR 1508.20). NEPA also requires evaluating a proposed action and alternatives at an equal level of analysis.

NEPA requires that a lead agency "include [in an EIS] appropriate mitigation measures not already included in the proposed action or alternatives" (40 CFR 1502.14(f)). An EIS must also include discussions of "means to mitigate adverse environmental impacts (if not fully covered under § 1502.14(f))" (40 CFR 1502.16(h)). In preparing a ROD under 40 CFR 1505.2, a lead agency must "[s]tate whether all practicable means to avoid or minimize environmental harm from the alternative selected have been adopted, and if not, why they were not. A monitoring and enforcement program shall be adopted and summarized where applicable for any mitigation."

1.2.2 California Environmental Quality Act

The State CEQA Guidelines (Cal. Code Regs., tit. 14, § 15064, subd. (f)(1)) require that an EIR be prepared whenever a project may have a significant effect on the environment. Section 15064, subdivision (d) states that "[i]n evaluating the significance of the environmental effect of a project, the lead agency shall consider direct physical changes in the environment which may be caused by the project and reasonably foreseeable indirect physical changes in the environment which may be caused by the project." An EIR is an informational document used to inform public agency decision makers and the general public of the significant environmental effects of a project, identify possible ways to mitigate or avoid the significant effects, and describe a range of reasonable alternatives to the project that could feasibly attain most of the basic objectives of the project while substantially lessening or avoiding any of the significant environmental impacts. When determining whether to approve a project, State and local public agencies are required by CEQA to consider the information presented in the EIR.

State CEQA Guidelines section 15126.6, subdivision (a) also requires that an EIR "describe a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project, and evaluate the comparative merits of the alternatives." A range of reasonable alternatives is analyzed to define issues and provide a clear basis for choice among options. CEQA requires that the lead agency consider alternatives that would avoid or reduce one or more of the

significant impacts identified for a project in an EIR. The State CEQA Guidelines state that the range of alternatives required to be evaluated in an EIR is governed by a "rule of reason;" the EIR needs to set forth only those alternatives necessary to permit a reasoned choice and to select and discuss them in a manner to foster meaningful public participation and informed decision making (§ 15126.6, subd. (f)). Consideration of alternatives focuses on those which are capable of avoiding or substantially lessening any significant effects of the project, even if these alternatives would impede to some degree the attainment of the project objectives, or would be more costly (§ 15126.6, subd (b)). CEQA does not require alternatives to be evaluated in the same level of detail as the proposed project.

CEQA requires that State and local government agencies consider the potential environmental effects of projects over which they have discretionary authority before taking action on those projects (Pub. Resources Code, § 21000 et seq.). CEQA also requires that each public agency avoid or mitigate to less-than-significant levels, wherever feasible, the significant environmental effects of projects it approves or implements. The significant environmental impacts are addressed in written findings that are supported by substantial evidence in the record (State CEQA Guidelines, § 15091). If a project would result in significant and unavoidable environmental impacts that cannot be feasibly mitigated to less-than-significant levels, the project can still be approved, but the lead agency's decision makers must make a "statement of overriding considerations" explaining in writing the specific economic, legal, social, technological, or other considerations that they conclude, based on substantial evidence, make those significant effects "acceptable" (State CEQA Guidelines, § 15093).

1.2.3 Type of Environmental Document

Program-level actions (and some project level actions) were analyzed in the Program Environmental Impact Statement/Environmental Impact Report (PEIS/R) (SJRRP 2011a). The program-level, or first-tier, analysis was performed in accordance with CEQ Regulations (40 CFR 1502.20), and consistent with California Public Resources Code sections 21093 and 21094; California Code of Regulations, Title 14, sections 15152 and 15168; and 40 CFR 1500.4(i), 1502.4(b), and 1502.20, among others. The program-level analysis has considered broad environmental effects of implementing the Settlement and has identified mitigation measures and performance standards that apply to project-level actions implemented as part of the Settlement.

Project-level analyses, such as this EIS/R which analyzes a portion of the Program area, can incorporate the findings of the PEIS/R by reference through "tiering," or incorporating by reference general discussions from the PEIS/R. Incorporation of previous analysis by reference is encouraged for NEPA analysis under the CEQ Regulations (40 CFR §§ 1500.4 and 1502.21).

> *Agencies shall incorporate material into an environmental impact statement by reference when the effect will be to cut down on bulk without impeding agency and public review of the action. The incorporated material shall be cited in the statement and its content briefly described. No material may be incorporated by reference*

> *unless it is reasonably available for inspection by potentially interested persons within the time allowed for comment. Material based on proprietary data which is itself not available for review and comment shall not be incorporated by reference (§ 1502.21).*

The State CEQA Guidelines also allow for incorporation by reference when project-specific analysis is tiered from previous analysis (§§ 15150 and 15152).

This EIS/R presents project-level analyses of the actions described in each alternative (see Chapter 2, "Description of Alternatives"). Other potential actions considered for evaluation but not included in the Action Alternatives (described in the Project Description Technical Memorandum, Attachment A, "Alternatives Evaluation" (SJRRP 2012b)) are not prohibited from future implementation, but would require separate analysis pursuant to NEPA and/or CEQA at a project level of detail.

1.2.4 Compliance and Permits Supported by this EIS/R

The SJRRP will obtain all necessary permits, as required by law. This EIS/R supports the needed permits, petitions, and similar compliance, coordination, and consultation efforts for the Project actions. Permits that may be required are shown in Table 1-2 and described in Chapter 27.0, "Consultation, Coordination, and Compliance."

Table 1-2.
Compliance, Consultation, and Coordination to Be Supported by this EIS/R

Resource Applicable	Laws/Regulations/Permits	Regulating Agency/Agencies
All	San Joaquin River Restoration Settlement Act	Secretary of the Interior
Wetlands and Waters of the United States	Section 10 of the Rivers and Harbors Act – Individual or General Permit	U.S. Army Corps of Engineers
	Section 401 of the Clean Water Act – Water Quality Certification or Waiver	Regional Water Quality Control Board
	Section 402 of the Clean Water Act – National Pollutant Discharge Elimination System permit(s)	State Water Resources Control Board and Regional Water Quality Control Board
	Section 404 of the Clean Water Act – Individual or General Permit	U.S. Army Corps of Engineers
Federally Listed Species	Section 7 of the Federal Endangered Species Act – Section 7 Consultation	U.S. Fish and Wildlife Service and National Marine Fisheries Service
Fish and Wildlife Resources	Magnuson-Stevens Fishery Conservation and Management Act	National Marine Fisheries Service
	Fish and Wildlife Coordination Act report	U.S. Fish and Wildlife Service
	Migratory Bird Treaty Act	U.S. Fish and Wildlife Service
	Bald and Golden Eagle Protection Act	U.S. Fish and Wildlife Service

Table 1-2.
Compliance, Consultation, and Coordination to Be Supported by this EIS/R

Resource Applicable	Laws/Regulations/Permits	Regulating Agency/Agencies
Cultural Resources	National Historic Preservation Act – Section 106 Consultation	State Office of Historic Preservation
Levees and Floodways	Section 14 of the Rivers and Harbors Act ("Section 408") – Permission	U.S. Army Corps of Engineers
	33 Code of Federal Regulations 208.10	U.S. Army Corps of Engineers
Bridges	Section 9 of the Rivers and Harbors Act and General Bridge Act of 1946 permit	U.S. Coast Guard
Water Rights	California Water Code – Water Right Petitions (including petitions for changes to Water Right Permits 11885, 11886, and 11887)	State Water Resources Control Board
State Lands	Land Use Lease	California State Lands Commission
Air Quality	Authority to Construct, Permit to Operate	San Joaquin Valley Air Pollution Control District
State-Owned Roadways	Encroachment Permit	California Department of Transportation

1.3 Relationship to Other SJRRP NEPA and CEQA Documents

Several environmental documents have been prepared previously to facilitate early actions needed to implement the Settlement. Documents include, but are not limited to, the following:

- *Water Year 2010 Interim Flows Project Final Environmental Assessment/Finding of No Significant Impact (EA/FONSI) and Initial Study/Mitigated Negative Declaration (IS/MND)* (SJRRP 2009).
- *Interim Flows Project – Water Year 2011 Supplemental EA/FONSI* (Reclamation 2010).
- *Draft PEIS/R* (SJRRP 2011a).
- *Interim Flows Project – Water Year 2012 Final Supplemental EA/FONSI* (SJRRP 2011b).
- *Mendota Dam Sluice Gates Replacement Project, Final EA/FONSI* (SJRRP 2011c).
- *Recirculation of Recaptured Water Year 2011 San Joaquin River Restoration Program Interim Flows EA/FONSI* (Reclamation 2011).
- *Final PEIS/R* (SJRRP 2012c).

- *Invasive Vegetation Monitoring and Management Final EA/FONSI* (SJRRP 2012d).
- *PEIS/R Record of Decision* (SJRRP 2012e).
- *2014 SJRRP Juvenile Fall-Run Chinook Salmon Trap and Haul Study* (Reclamation 2014).
- *SJRRP: Salmon Conservation and Research Facility and Related Management Actions Project* (DFW 2014).

1.4 Purpose and Need for Action and Project Objectives

NEPA regulations require a statement of "the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action" (40 CFR 1502.13). The State CEQA Guidelines require a clearly written statement of objectives, including the underlying purpose of a project (State CEQA Guidelines, § 15124, subd. (b)).

The purpose and objective of the Project are to implement portions of the Settlement consistent with the Act. The Act authorizes and directs the Secretary to implement the Settlement. Specifically, this Project is intended to implement Paragraphs 11(a)(1) and 11(a)(2) of the Settlement, which are authorized in Section 10004(a)(1) of the Act.

Paragraph 11(a)(1)

> *Creation of a bypass channel around Mendota Pool to ensure conveyance of at least 4,500 cfs from Reach 2B downstream to Reach 3. This improvement requires construction of a structure capable of directing flow down the bypass and allowing the Secretary to make deliveries of San Joaquin River water into Mendota Pool when necessary;*

Paragraph 11(a)(2)

> *Modifications in channel capacity (incorporating new floodplain and related riparian habitat) to ensure conveyance of at least 4,500 cfs in Reach 2B between the Chowchilla Bifurcation Structure and the new Mendota Pool bypass Channel;*

The Settlement specifies the need, which requires modifications to Reach 2B and construction of a bypass around Mendota Pool in support of achieving the Restoration Goal (Settlement Paragraph 2):

> *… a goal of this Settlement is to restore and maintain fish populations in "good condition" in the main stem of the San Joaquin River below Friant Dam to the confluence of the Merced River, including*

naturally-reproducing and self-sustaining populations of salmon and other fish (the "Restoration Goal").

The purpose to provide increased capacity and floodplain and riparian habitat in Reach 2B respond to the need to restore and maintain fish populations in "good condition" by providing fish passage and rearing habitat which benefit salmon and other native fish. Without the Project in Reach 2B, restoration activities would be unlikely to achieve the Settlement goals.

1.5 Responsibilities of Lead Agencies, Responsible Agency, and Implementing Agencies

As previously described, Reclamation is the lead NEPA agency and CSLC is the lead CEQA agency in preparing this EIS/R. The actions identified in this EIS/R include actions to be undertaken by Reclamation and CSLC. The effects of these actions are identified in this EIS/R.

The Settlement identifies the Secretary as the lead Federal entity responsible for implementation and USFWS as the lead Federal agency responsible for reintroduction of spring-run and fall-run Chinook salmon. The Secretary has designated Reclamation to act as the lead Federal entity responsible for implementation of the Settlement. The Settlement also identifies the Secretary of the U.S. Department of Commerce, through NMFS, as a necessary participant to allow for permitting the reintroduction of spring-run Chinook salmon. The Settlement also anticipated involvement of the California Natural Resources Agency through DWR and DFW. Therefore, the Implementing Agencies include Reclamation, USFWS, NMFS, DWR, and DFW.

Reclamation and CSLC have coordinated with the Settling Parties and Implementing Agencies in preparation of this EIS/R. In addition, several agencies accepted the invitation to participate as cooperating agencies under NEPA, including the U.S. Environmental Protection Agency (EPA), the U.S. Army Corps of Engineers (Corps), NMFS, and Central California Irrigation District. The cooperating agencies have provided input that is being considered in preparation of this EIS/R.

Additional information on responsible agencies and permit requirements is provided in Chapter 27.0, "Consultation, Coordination, and Compliance."

1.6 Project Study Area

1.6.1 Geographic Area Description

The Project study area or "Project area" includes areas that may be affected directly or indirectly by the Project alternatives. The Project footprint (township 13S, range 15E), shown in Figure 1-2, has two major components: Reach 2B and the Mendota Pool Bypass. Reach 2B generally includes the area from the San Joaquin River Control Structure near the Chowchilla Bypass downstream to Mendota Dam. Potential Project

improvements in Reach 2B, which vary by alternative, extend from the Chowchilla Bifurcation Structure on the upstream end to the head of the potential Mendota Pool Bypass channel or to Mendota Dam on the downstream end. However, Reach 2B improvements may also include areas just upstream of the Chowchilla Bifurcation Structure and may continue downstream of the head of the Mendota Pool Bypass or Mendota Dam, including the Pool area, as necessary to meet Project goals and objectives. The lateral extent of potential Project Reach 2B improvements, which varies by alternative, includes lands to the north and south of the San Joaquin River in Reach 2B.

The Mendota Pool Bypass element of the Project alternatives generally includes the area from the downstream end of the Reach 2B improvements to a tie-in location in Reach 3. Improvements for the Mendota Pool Bypass, which vary by alternative, extend from the area south of Mowry Bridge over Fresno Slough to the area north of Mendota Dam where the Bypass ties into Reach 3. The Mendota Pool Bypass element of the Project alternatives also includes areas adjacent to and on the west side of Mendota Pool and Fresno Slough and areas to the south of the potential Project Reach 2B improvements. Areas indirectly affected by this Project include portions of Reach 3 downstream and Reach 2A upstream that are outside the direct Project footprint.

The Project area reflects current estimates of areas that may be affected by the Project alternatives. In this EIS/R, the area where direct and indirect effects may occur differs according to resource area; therefore, the geographic range and environmental conditions described herein vary by resource.

1.6.2 Description of Existing Conditions within the Study Area

At the upstream end of the Project, the Chowchilla Bifurcation Structure is used to control and route flood releases from Friant Dam and the upstream watershed into Reach 2B and the Chowchilla Bypass, a flood protection project on the San Joaquin River. Under no-flow conditions, plunge pools (approximately 7 feet deep and 10 feet deep, respectively) can be observed at the downstream base of the Chowchilla Bifurcation Structure in both the San Joaquin River and the Chowchilla Bypass.

Reach 2B ends on the downstream end at the Mendota Dam, which creates Mendota Pool. The Delta-Mendota Canal terminates at the Pool, which distributes water deliveries from the Delta to Exchange Contractors via the Main Canal, Helm Ditch, Columbia Canal, Main Lift Canal, and Outside Canal. The Pool is shallow with little storage volume, and the pool elevation is maintained for the purposes of hydraulic head into Fresno Slough. The Pool provides only minimal transitory storage above the operating elevation and, therefore, does not provide substantial flood control protection. During flood releases, the flashboards are removed at Mendota Dam allowing the backwatered Pool to become part of the flowing river.

Flood flows through Mendota Pool are released from Friant Dam, Pine Flat Dam, or both. Friant Dam flood control releases may be diverted into Reach 2B at the Chowchilla Bifurcation Structure, and Pine Flat Dam flood control releases may be diverted into Mendota Pool via the James Bypass and Fresno Slough. Pine Flat Dam flood control releases have priority over Friant Dam flood control releases, so depending on the

available capacity in Reach 3, a portion or all of the flow from Reach 2A may be diverted into the Chowchilla Bypass. Pine Flat Dam flood control releases into Mendota Pool occur in wet years (approximately 1 in 5 years with the SJRRP). Accordingly during wet years, flow in Reach 2B may be reduced during flood control releases from Pine Flat Dam.

The Project area includes only one existing private crossing, a dip-crossing at San Mateo Avenue, consisting of a culvert to convey low flows and an earthen embankment supporting the roadbed, which is overtopped during higher flows.

The San Mateo Avenue crossing is the approximate limit of the backwater effects of the Pool. Downstream of San Mateo Avenue, the river channel is inundated as a result of the Pool water surface elevation. Upstream of the crossing, the channel is only wetted during Interim Flows or flood releases from Friant Dam. The Pool and associated river channel were drained approximately every 2 years to inspect and perform maintenance on Mendota Dam. Recent repairs at Mendota Dam have reduced this need to dewater the Pool for dam inspections.

Several water diversions (including Lone Willow Slough and the Columbia Canal), canals, lift stations, and groundwater wells exist within the Project area. Additionally, electrical and gas distribution lines and water pipelines lie within the Project area.

Existing Land Use and Habitat

A narrow corridor of riparian and aquatic habitat exists along the river corridor, levees, and at Mendota Pool; otherwise, land use within and surrounding the Project area is primarily agriculture with the exception of the water management facilities at the Pool.

The Pool backwater supports perennial riparian vegetation, predominantly willow riparian and cottonwood riparian forest communities with emergent wetland communities. Upstream of San Mateo Avenue and prior to Interim Flows, the channel exhibited a sandy substrate with little to no in-channel vegetation (Figure 1-3). Existing vegetation along the banks of the channel in these areas consists predominantly of riparian scrub and willow scrub communities.

Existing Fish Population and Habitat Conditions

Prior to the start of Interim Flows in October 2009, Reach 2B upstream of San Mateo Avenue was dry except during flood flows (approximate frequency was every 2 to 3 years), consequently there was very limited in-channel habitat features. The Pool contained mostly introduced fishes and a few native fish. The biennial dewatering of the Pool left the Pool site mostly dry, but some locations held standing water during the several week period the Pool was drained in mid-winter.

Figure 1-3.
Reach 2B Channel without Interim Flows (12/15/09)

The Reach 2B channel bed is composed of unconsolidated fine sand and, prior to Interim Flows, there was little definition of the channel bed, which is typical for sand bed systems. No pool-bar structure or bed features occurred which would typically be used in gravel bed or coarser systems to classify and evaluate fish habitat features (pools, riffles, runs) or conditions (instream cover, overhead cover, etc.). Aquatic habitat in Reach 2B upstream of San Mateo Avenue was limited because there is a long history of the channel being dry prior to the start of Interim Flows. Riparian vegetation was limited to the levees along the channel banks. In the lower portion of Reach 2B, the channel was defined where vegetation had been established along the backwatered portion from the Pool between Mendota Dam and San Mateo Avenue. The Pool was bordered by emergent, wetland and riparian vegetation including mature cottonwood trees. Aquatic habitat in this section of river was affected by the backwatering of Mendota Dam and sedimentation in the Pool.

Since the start of Interim and Restoration flows, Reach 2B has increased inundation and establishment of hydrophilic vegetation. Aquatic habitat between the Chowchilla Bifurcation Structure and San Mateo Avenue has developed into a series of low gradient riffles, flatwater glides, and mid-channel pools and the San Joaquin River arm of Mendota Pool continues to hold water year-round. With the exception of biennial dewatering, Pool elevations are maintained near capacity.

Existing Structures

Chowchilla Bifurcation Structure

The most upstream structure is the Chowchilla Bifurcation Structure (Figure 1-2 and Figure 1-4). This structure is used to route flood flows down the Chowchilla Bypass. The bifurcation has two structural components: the river control structure, which spans the

San Joaquin River, and the bypass control structure, located at the head of the Chowchilla Bypass. The bifurcation structure has wingwalls bounding four gated bays on each channel. The bays are essentially 20-foot-wide by 18-foot-high box culverts containing a trash rack on the upstream side (Figure 1-5). The four bays discharge across a row of energy dissipaters (dragons teeth) then over a concrete slab that is bounded on the downstream end by a 2-foot-high concrete weir. Immediately below the concrete weir is a row of riprap sitting against the concrete weir and above the sand bed of Reach 2B (Figure 1-6). Upstream and downstream of the structure is the sand bed of Reach 2A and 2B, respectively.

San Mateo Avenue Crossing

The present crossing of Reach 2B is a dip crossing or low-water crossing (Figure 1-7, Figure 1-8). Flows less than approximately 150 cfs are routed through a culvert beneath the road. At flows above approximately 150 cfs, the road is inundated (Houk 2009). The north (Madera County) portion of the crossing is within public right-of-way, but the south (Fresno County) portion of the crossing is on private land, essentially rendering it a private river crossing.

Mendota Dam and Mendota Pool

Mendota Dam (Figure 1-2 and Figure 1-9), at the downstream end of Reach 2B, forms a pool approximately 7 miles long to San Mateo Avenue. The downstream 2 to 3 miles of the channel is bordered by mature trees along the north bank. Typically, the Pool receives water from the Delta-Mendota Canal which supplies water to the Helm Ditch, Main Canal, Outside Canal, Main Lift Canal, Fresno Slough, and Columbia Canal. The Pool is shallow and was drained about every 2 years for dam inspection and maintenance. Recent repairs at Mendota Dam have reduced this need to dewater the Pool for dam inspections.

1.6.3 Description of Local Hydrology

As part of the SJRRP, Restoration Flows are released from Friant Dam based on water year type and other factors, as described in the *Restoration Flow Guidelines* (SJRRP 2013), and conveyed to Reach 2B (see Figure 1-10). Flows conveyed into or diverted from Reach 2B and the Mendota Pool include:

- Restoration (and Interim flows prior to 1/1/2014).
- Exchange Contractor deliveries to Mendota Pool from the San Joaquin River.
- Exchange Contractor deliveries to Mendota Pool from the Delta-Mendota Canal.
- Millerton Lake flood releases.
- Pine Flat Reservoir flood releases.
- Diversions to Mendota Pool via groundwater pump-ins.
- Diversions from Mendota Pool via the Columbia Canal, Mendota Dam (for Arroyo Canal in Reach 3), Helm Ditch, Main Canal, Outside Canal, Fresno County Waterworks District Canal, Fresno Slough, and Mowry pumps.
- Diversions from the river via Lone Willow Slough and other pumps for riparian rights diversions.

There are three basic flow scenarios involving Restoration Flows, flood flows, and water deliveries that would typically occur in Reach 2B:

- Restoration Flows would proceed through Reach 2B and irrigation deliveries and diversions would occur in Mendota Pool with no interaction between the Restoration Flows in Reach 2B and Mendota Pool. This would typically occur in critical-low to normal-wet water year types.
- Flood releases from Millerton Lake may be diverted from Reach 2B into the Chowchilla Bypass as well as to Mendota Pool where they can be used to fulfill water contracts or by legal water rights holders while alleviating pressure on the flood system. This would occur primarily in normal-wet to wet water year types. Some portion of these flows is anticipated to perform as Restoration Flows in Reach 2B, but the flood management agencies will have ultimate discretion in directing flood flows.
- Flood releases from Pine Flat Reservoir may be bypassed to the San Joaquin River via Fresno Slough and Mendota Pool, typically in wet water year types. Due to capacity restrictions downstream of Reach 2B, the addition of these flows further restricts the amount of flow that can enter Reach 2B, and more San Joaquin River flows will be diverted into the Chowchilla Bypass to compensate. Some portion of the San Joaquin River flows are anticipated to perform as Restoration Flows in Reach 2B, but the flood management agencies will have ultimate discretion in directing flood flows.

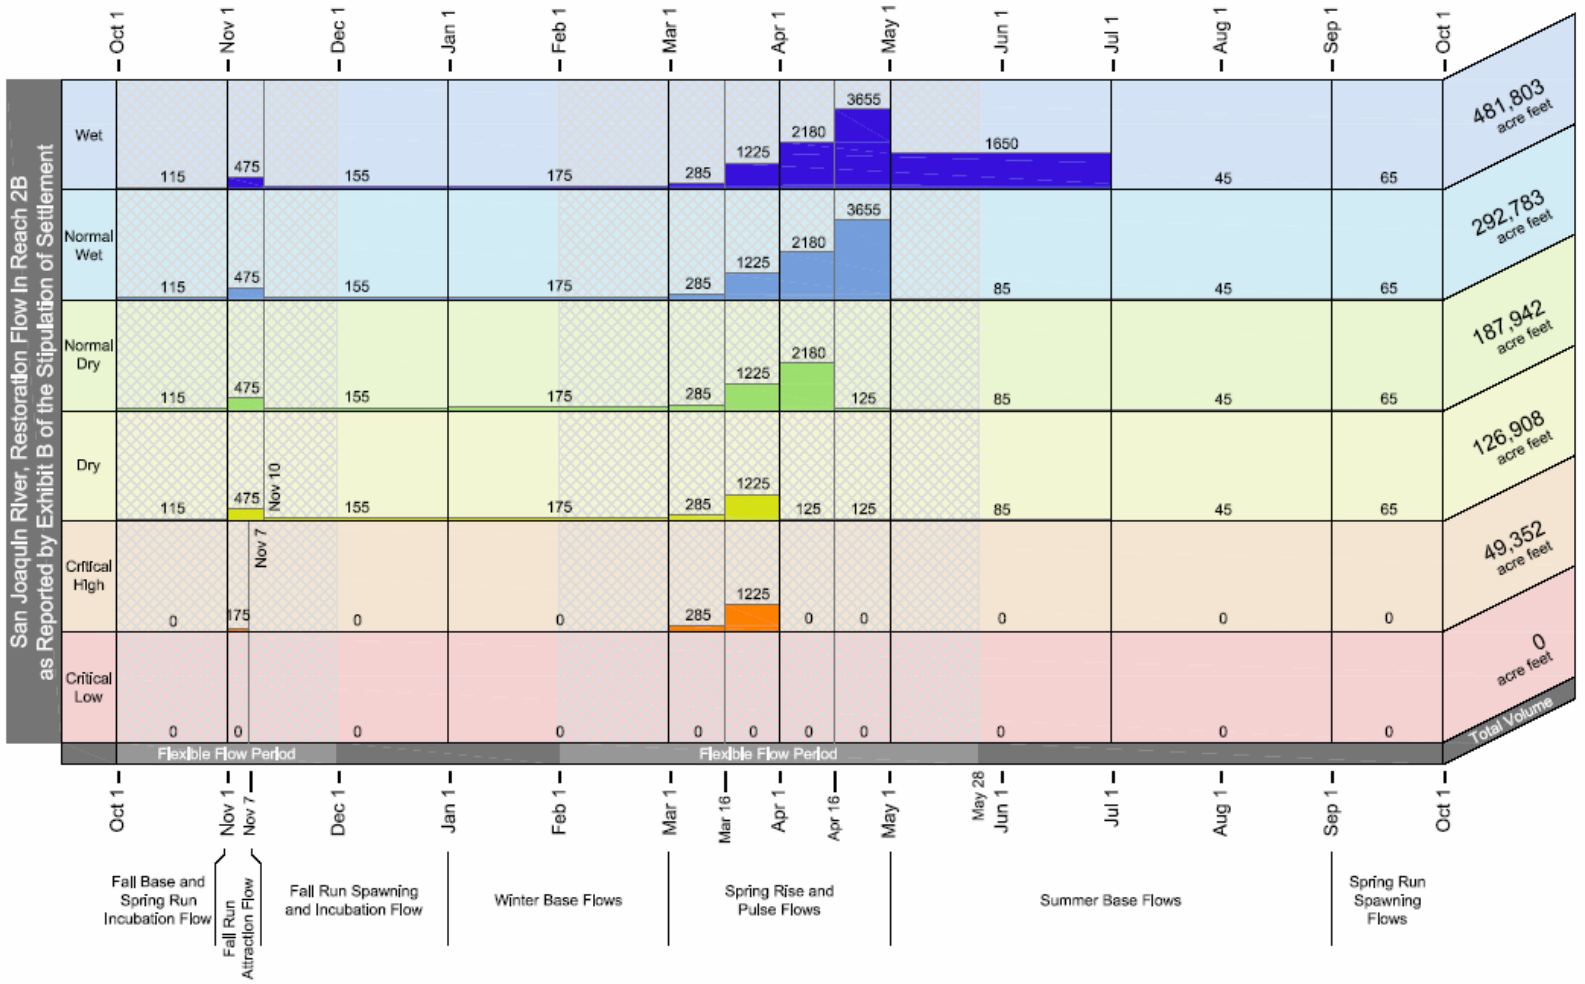
In addition to the above flow scenarios, the Restoration Administrator has the ability to manage Restoration Flows shown in Figure 1-10 to meet the Program's goals and objectives. These management strategies include reshaping the flow block by moving it earlier in the schedule, later in the schedule, compressing the flow block, or extending it consistent with the provisions in the Settlement.

1.7 Organization of this EIS/R

This EIS/R is organized as shown below.

Executive Summary presents the purpose and intended uses of this EIS/R, describes lead agencies, Project location, Project background and future actions, need for action, and Project purpose/objectives, provides an overview of the alternatives under consideration and major conclusions of the environmental analysis, documents the known areas of controversy and issues to be resolved, and summarizes in a table the environmental impacts, mitigation measures, and significance conclusions for the alternatives under consideration. It also presents a comparison of the four Action Alternatives.

Chapter 1.0, "Introduction" summarizes Project background and context, scope of this EIS/R, Project purpose and need for action and objectives, Project area, and EIS/R organization.



1

2 1 Hydrographs reflect assumptions about seepage losses and tributary inflows which are specified in the Settlement.
3 2 Reach 2B hydrographs are labeled as Reach 3 in Settlement Exhibit B.

4 **Figure 1-10.**
5 **Restoration Flow hydrographs by restoration year type (Reach 2B)**

Chapter 2.0, "Description of Alternatives" summarizes the process that was implemented to develop, evaluate, and select the alternatives, describes the alternatives including the No-Action/No-Project Alternative, describes options and alternatives that were considered throughout the alternatives formulation process but were eliminated from further consideration and the reasons for their elimination, and describes the State, Federal, and other agency actions (permits and approvals) required in order to implement the Project.

Chapter 3.0, "Considerations for Describing the Affected Environment and Environmental Consequences," describes the Project area, and the approach and terms used to describe the environmental and regulatory setting and environmental consequences for the resource topics presented in Chapters 4.0 through 24.0.

Chapters 4.0 through 24.0 include the environmental and regulatory settings for 21 resource topics, and discussions of methods, significance criteria, environmental impacts, and mitigation measures for potential direct and indirect impacts.

Chapter 25.0, "Cumulative Impacts," provides an analysis of overall cumulative effects of the Project alternatives, including the No-Action/No-Project Alternative, together with other past, present, and reasonably foreseeable future plans and projects to supplement information contained in the PEIS/R (SJRRP 2011a).

Chapter 26.0, "Other NEPA and CEQA Considerations," describes potential significant and unavoidable impacts, the relationship of short-term uses and long-term productivity, irreversible and irretrievable commitments of resources, and growth-inducing impacts of implementing the Project. It also describes the Preferred Alternative, compares the Action Alternatives to each other, and describes the Mitigation Monitoring and Reporting Program (MMRP).

Chapter 27.0, "Consultation, Coordination, and Compliance," summarizes public involvement activities under NEPA and CEQA; consultation and coordination with Federal, State, regional, and local agencies; agencies and organizations consulted; and areas of controversy and unresolved issues. This chapter also describes Federal and State laws and regulations that apply to project-level compliance. In addition, this chapter lists potential permits, regulatory approvals, and needed authorizations.

Chapter 28.0, "References," provides a bibliography of sources cited throughout this EIS/R.

Chapter 29.0, "List of Preparers," lists individuals who participated in preparing this EIS/R and provides qualifications for those individuals.

Chapter 30.0, "Index," lists key terms and topics discussed throughout this EIS/R, and the location of the most relevant discussion or definition of the terms and topics.

Appendices contain background information that supports this EIS/R. The appendices include technical information relevant to the resource topics described in Chapters 4.0 through 24.0.

2.0 Description of Alternatives

As part of implementation of the Stipulation of Settlement (Settlement), U.S. Department of the Interior, Bureau of Reclamation (Reclamation) and California State Lands Commission (CSLC) have prepared this project-level Environmental Impact Statement/Environmental Impact Report (EIS/R) for the Mendota Pool Bypass and Reach 2B Improvements Project (Project). This EIS/R presents a No-Action/No-Project Alternative (hereafter called the No-Action Alternative) and four Action Alternatives to implement the Project. Of the four Action Alternatives, there are two methods of bypassing Restoration Flows around Mendota Pool, two floodplain widths, and four ways to divert water into Mendota Pool. Project alternatives include the following:

- No-Action Alternative.
- Alternative A (Compact Bypass with Narrow Floodplain and South Canal).
- Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative.
- Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal).
- Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal).

2.1 Alternatives Formulation Process

An early step in producing this EIS/R was the formulation of the alternatives that are evaluated in this document. This section presents an overview of the development of the Action Alternatives. Each of the four Action Alternatives developed for the Project consists of a floodplain width which passes 4,500 cubic feet per second (cfs), a method to bypass Restoration Flows around Mendota Pool, and a method to deliver water to Mendota Pool. These objectives are consistent with the Project's purpose and need.

2.1.1 Alternatives Development Process Overview

Alternatives development progressed through several stages. The process began with the Initial Options Technical Memorandum (TM) (San Joaquin River Restoration Program [SJRRP] 2010a) which presented initial options for meeting Project goals and objectives. Input from Program Work Groups, stakeholders, and the public was collected. Subsequently, the initial options were refined based on impact evaluations, additional engineering analyses (appraisal level design), additional data collection, screening criteria, and public input to produce initial alternatives. These initial alternatives were evaluated (SJRRP 2012, Attachment A, "Alternatives Evaluation") using a set of evaluation and screening criteria developed pursuant to National Environmental Policy Act (NEPA) and California Environmental Quality Act (CEQA) requirements, and developed in coordination with Project proponents, to produce the range of reasonable alternatives presented here.

Using information obtained through evaluation and refinement, the final set of bypass, floodplain, and structure options were combined to create the Action Alternatives for the EIS/R. These Project alternatives provide a range of approaches to meet the Project purpose and need, and allows for an assessment of environmental effects.

Opportunities for stakeholder involvement were integrated throughout the alternatives formulation process. Figure 2-1 presents a graphical view of the process.

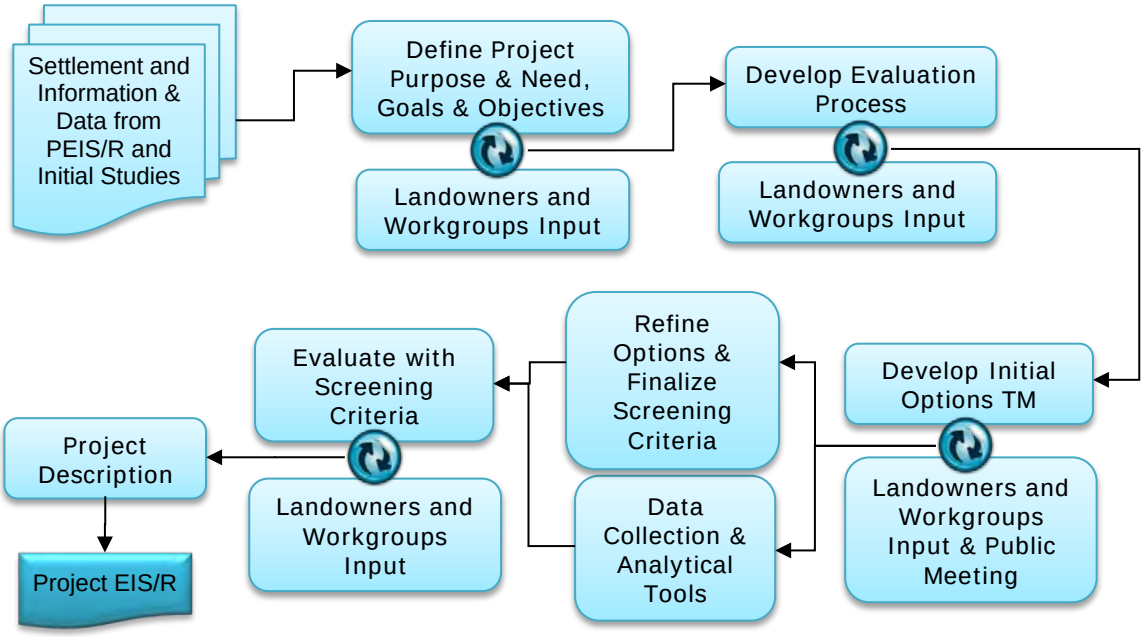


Figure 2-1.
Alternatives Formulation Process

2.1.2 Stakeholder Involvement

The alternatives development process provided opportunities for early stakeholder involvement and input. Primary stakeholders include Federal, State, and local agencies, landowners, the Technical Advisory Committee (TAC), non-governmental organizations (NGOs) and the public. The following sections describe the level of involvement of the various stakeholder groups in the alternatives formulation.

Federal, State, & Local Agencies

Federal and State Implementing Agencies involved in the SJRRP have representatives in the Technical Work Groups and Subgroups. These groups provide support for the development, evaluation, and refinement of concepts. The following groups had input during the alternatives formulation:

Fisheries Management Workgroup:

- California Department of Water Resources (DWR) presented the initial options for the Reach 2B floodplain and Mendota Pool Bypass alignment at the November 10, 2009, meeting.
- Refinement of initial options criteria and requirements related to fisheries was discussed during the December 11, 2009, Fisheries/Alternatives Subgroup.
- The design flow for fish screening was discussed on February 3, 2010.
- Further refinements to the floodplain and Mendota Pool bypass designs were presented and discussed on June 17, 2010, and passage requirements for non-salmonid native fish were also discussed.
- Passage at structures and passage design criteria were presented and discussed on August 19, 2010, and a recommendation was made to present to the Anadromous Fish Screen Program for feedback on fish screen designs.
- A special subgroup was convened twice, on October 27, 2010, and February 24, 2011, with members of the workgroup and other agency staff with expertise in fish passage structure design to discuss technical and engineering issues related to the design of the fish passage structures.
- A workshop was held on June 28, 2011, to discuss alternatives formulation.
- Criteria for fish passage at structures were discussed at a meeting on July 29, 2011.
- A meeting was held on October 25, 2011, to discuss the potential for rock ramp type fish passage facilities.
- A workshop was held on January 10, 2012, to provide an overview of the Ecosystem Diagnosis and Treatment modeling process.
- Members of the workgroup participated in several calls with the Project team to discuss technical issues, approaches to resolving issues, and on-going analyses related to fisheries management.
- The workgroup was involved in the review and comment of some Project-specific documents: the Initial Options TM, Analytical Tools TM, the Project Description TM, and this EIS/R.
- In addition, many calls and emails were exchanged with individuals in the workgroup to discuss specific issues.

Environmental Compliance and Permitting Workgroup:

- The Reach 2B consultant presented the initial options for the Reach 2B floodplain and Mendota Pool Bypass alignment at the December 1, 2009, meeting.
- The approach and use of analytical tools in the alternatives evaluation was presented and discussed at the meeting on May 18, 2010.
- DWR presented the Reach 2B draft borrow areas investigation plan at the meeting on February 15, 2011.

- The workgroup was involved in the review and comment of all Project-specific documents: the Initial Options TM, Environmental Data Needs TM, Analytical Tools TM, Environmental Survey Results TM, and this EIS/R.
- In addition, the Project team has regularly attended the workgroup's meetings to provide Project updates and answer questions.

Engineering and Design Workgroup:

- Engineering and Design Workgroup members developed pre-appraisal level structural options descriptions that addressed channel and floodplain conveyance given the site boundary conditions and a range of potential floodplain and channel characteristics.
- Coordination with the workgroup has resulted in completion of an informal technical review by Reclamation's Technical Service Center in Denver, a Design, Engineering, and Construction review, and completion of a Value Planning Study organized by Reclamation.
- In addition, the Project team has regularly attended the workgroup's weekly conference calls to provide Project updates and answer questions.

Water Management Workgroup:

- The Water Management Workgroup developed flow hydrographs for the purpose of evaluating site-specific alternatives under a range of potential flow schedules. Additionally, the group coordinated with Reclamation and other stakeholders on Program operational guidelines.

Members of all the workgroups were invited to a presentation on the alternatives evaluation to provide input on the mechanism for evaluating the alternatives at a meeting on February 18, 2011.

Fresno and Madera counties:

- Representatives from DWR spoke on the phone (July 27, 2010) and met with the Madera County Road Department (October 5, 2010) to describe the purpose of the Project and its effects on the San Mateo Avenue crossing and Drive 10 ½. DWR solicited input on the use and need for the crossing, as well as desired improvements.
- A representative of DWR spoke on the phone with the Fresno County Road Maintenance Department on July 27, 2010, to describe the purpose of the Project and its effects on the San Mateo Avenue crossing. DWR solicited input on the use and need for the crossing, as well as desired improvements, but Fresno County did not desire to provide input because the crossing is not located within their right-of-way.

Landowners

Meetings are held periodically with the landowners and representatives who have a stake in the Project or are located along the channel in the Project area to provide updates on Project status and collect input on alternatives development.

- Initial landowner consultation began prior to July 2009.
- The Reach 2B floodplain pre-appraisal level themes and Mendota Pool Bypass alignments were presented by DWR at the November 17, 2009, meeting.
- Project status updates, overview of the publically available project-specific documents, concept refinement of the San Mateo Avenue crossing design and use of Little San Joaquin Slough, and the alternatives development process were presented and discussed, and comments were accepted at the May 27, 2010, meeting.
- Project status updates, overview of new publically available project-specific documents, CSLC preliminary findings regarding sovereign and public trust lands, and DWR's land acquisitions process were presented and discussed, and comments were accepted at the March 24, 2011, meeting.
- The CSLC draft administrative sovereign and public trust land maps for Reach 2B, a brief Program update, and a Reach 2B Project update were presented at the October 3, 2011, meeting.
- The Project effects on Mendota Pool and other operations, details of Project components, and effects on infrastructure using large-scale maps were presented at the November 14, 2011, workshop.
- Overview of borrow material needs and the status of geotechnical explorations were presented during the December 16, 2011, conference call.
- Project overview, status, and a brief review of the alternatives were presented to stakeholders associated with Fresno Slough at the May 31, 2012, meeting.
- A meeting was held on January 29, 2013, to introduce the consensus-based alternative concept and approach to the adjacent landowners, canal companies, irrigation districts, levee districts, cities, and the Settling Parties. The consensus-based alternative approach gives these entities the opportunity to provide input on the Project course of action, and their input has been considered during the selection of a preferred alternative.
- Program status updates, Project EIR/S process and schedule, the landowner consensus-based alternative, flood management considerations, and geotechnical investigations techniques, strategy, and schedule were presented and discussed with stakeholders at the August 26, 2013, meeting.
- Program and Project status updates, geotechnical investigation updates, Reach 2B and Mendota Pool operations, levee and structure designs were presented and discussed with stakeholders at the December 20, 2013, workshop.
- Program and Project status updates including review of the landowner consensus-based preferred alternative, and design and field investigations were discussed with stakeholders at the October 15, 2014, meeting.

- In addition, in-person meetings were held with individual landowners and many calls and emails were exchanged with individual landowners to discuss specific issues.

Technical Advisory Committee

The TAC consists of six voting members selected by the Settling Parties to assist the Restoration Administrator regarding areas outlined in the Settlement. Coordination and information sharing between the TAC and the Implementing Agencies is ensured by two non-voting members representing the State agencies (DWR and California Department of Fish and Wildlife [DFW]) and three liaisons from the Federal agencies (Reclamation, National Marine Fisheries Service [NMFS], and U.S. Fish and Wildlife Service [USFWS]). The TAC holds regular meetings as part of its mission on many aspects for the Restoration Administrator, including some meetings that have focused on the Project.

- A meeting was held on September 22, 2010, to review the Project background, fish passage approaches, and fisheries habitat approaches.
- A meeting was held on April 14, 2011, to present the initial alternatives and alternatives evaluation results.
- A meeting was held on January 11, 2012, to present a conceptual habitat assessment approach.
- A meeting was held on January 28, 2013, to discuss the TAC's approach to evaluating the floodplain habitat in the Project alternatives.
- A meeting was held on March 20, 2013, to discuss the results of the TAC's approach to evaluating the floodplain habitat in the Project alternatives.
- A meeting was held on September 17, 2014, to discuss the preferred alternative for the Project.

Non-Governmental Organizations

Several meetings between the Program and NGOs have been held. NGOs typically in attendance at these meetings include: the San Joaquin River Partnership (Audubon California, Defenders of Wildlife, Ducks Unlimited, Natural Resources Defense Council [NRDC], Point Blue Conservation Science, Revive the San Joaquin, River Partners, Sierra Foothill Conservancy, San Joaquin River Parkway and Conservation Trust, the Bay Institute, the Nature Conservancy, the Trust for Public Land, Trout Unlimited, Tuolumne River Trust), Resources Legacy Fund, Proteus, the Environmental Opportunities Group (the Trust for Public Land, American Rivers, San Joaquin River Parkway and Conservation Trust, River Partners, the Nature Conservancy, Audubon California, NRDC, and Trout Unlimited), and others.

- A meeting was held with the San Joaquin River Partnership on March 19, 2013, to provide a status update on the Project and to present and discuss the Project alternatives.
- A meeting was held with Resources Legacy Fund, Proteus, and the Mayor of Mendota on December 10, 2013, to provide a status update on the Project and to present and discuss the Project alternatives.

- Meetings were held with the Environmental Opportunities Group on December 16, 2013, January 17, 2014, and August 14, 2014, to provide a status update on the Project and to present and discuss the Project alternatives.
- Meetings were held with the Resources Legacy Fund and Proteus on May 2, 2014, and September 30, 2014, to provide a status update on the Project and to present and discuss the Project alternatives.
- A meeting was held with Pete Dangermond (formerly with California State Parks, now under contract with the Resources Legacy Fund) and Dave Koehler (Executive Director of San Joaquin River Parkway and Conservation Trust) on August 6, 2014, to provide a status update on the Project and to present and discuss the Project alternatives.
- In addition, representatives of various NGOs attend the Program's Technical Feedback Group meetings as well as other meetings with the Program and agencies (e.g., DWR Upper San Joaquin River Regional Flood Management Plan process meetings).

Public

Reclamation and DWR held two public scoping meetings in July 2009, for the purpose of initiating the NEPA and CEQA public input processes on the Project. During the scoping meetings and throughout the public comment period, Reclamation and DWR accepted comments on the Project regarding the range of alternatives, the environmental effects, and the mitigation measures to be considered in this EIS/R. Suggestions regarding the pre-appraisal level themes were documented in the Scoping Report (SJRRP 2010b) and have been considered in this EIS/R.

The SJRRP organized and held several public outreach meetings in the form of Technical Feedback Groups. The Project proponents participated in the April 28, 2010, Restoration Goal Technical Feedback Group meeting by providing an overview and discussion of the Initial Options TM and Analytical Tools TM and in the May 17, 2012, Restoration Goal Technical Feedback Group meeting by providing a status update on the Project and an overview of technical challenges the team worked on during alternatives formulation.

The SJRRP also organized and held a Spanish-speaking community meeting on December 9, 2014. An overview of the SJRRP was presented, the Project and Project alternatives were discussed, input from the community was requested, and discussion and feedback from the community was facilitated through small group discussion.

2.1.3 Initial Options Formulation

The initial options were formulated based on existing information and data, preliminary engineering analyses and screening, as well as input from Program Work Groups, stakeholders, and the public. Individual and group landowner meetings were held to present and obtain input on the initial options presented. One of the guiding Project objectives and subsequent analyses pertain to flow conveyance. A one-dimensional hydraulic model was completed during the development of initial channel/floodplain options to examine the largest range of practical and feasible floodplain widths given a reasonable range of management and habitat restoration strategies. Initial screening

involved reviewing the options for consistency with the Settlement requirements and for technical feasibility. Any option deemed technically infeasible or beyond the scope of the Settlement or contrary to its requirements were not carried forward for further consideration.

2.1.4 Alternatives Formulation

An early step in developing this EIS/R was the formulation of the Action Alternatives addressed by this document. The process diagram shown in Figure 2-2 depicts the steps in the formulation process.

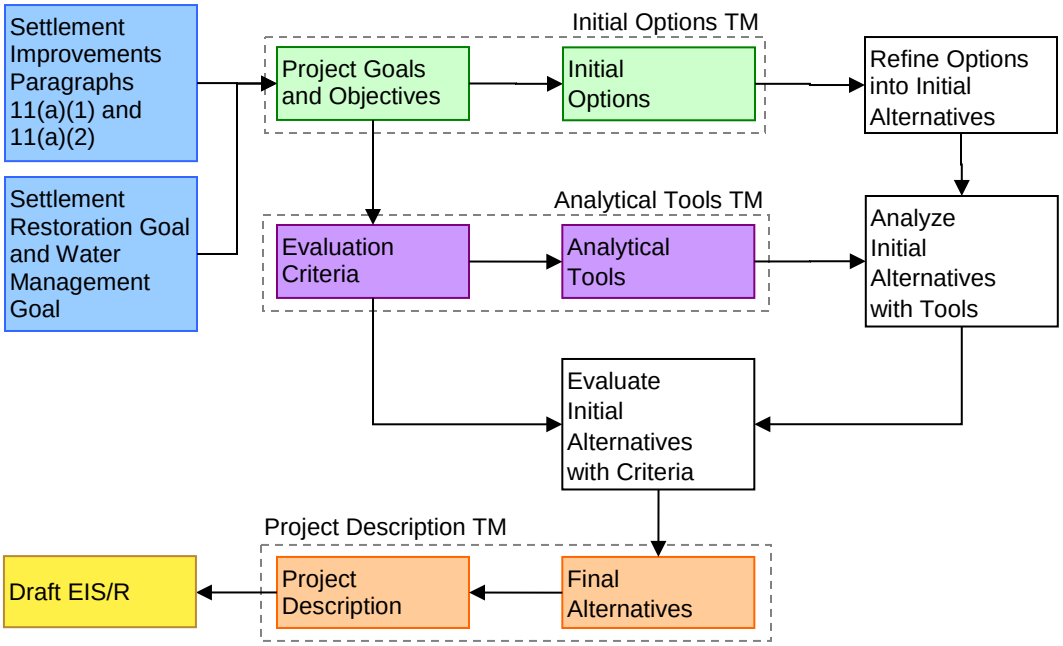

Figure 2-2.
Alternatives Formulation Process Diagram

The initial guidance for developing the Project comes from language in the Settlement, specifically the Settlement's goals and the Settlement defined improvements. These goals and improvements are consistent with the Project's purpose and need (see Section 1.4). The Settlement goals are:

The Restoration Goal (Settlement Paragraph 2):

> *… a goal of this Settlement is to restore and maintain fish populations in "good condition" in the main stem of the San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally-reproducing and self-sustaining populations of salmon and other fish (the "Restoration Goal").*

The Water Management Goal (Settlement Paragraph 2):

> *…a goal of this Settlement is to reduce or avoid adverse water supply impacts to all of the Friant Division long-term contractors that may result from the Interim Flows and Restoration Flows provided for in this Settlement (the "Water Management Goal").*

The Mendota Pool Bypass and Reach 2B improvements defined in the Settlement are (Settlement Paragraph 11[a]):

> *(1) Creation of a bypass channel around Mendota Pool to ensure conveyance of at least 4,500 cfs from Reach 2B downstream to Reach 3. This improvement requires construction of a structure capable of directing flow down the bypass and allowing the Secretary to make deliveries of San Joaquin River water into Mendota Pool when necessary;*
>
> *(2) Modifications in channel capacity (incorporating new floodplain and related riparian habitat) to ensure conveyance of at least 4,500 cfs in Reach 2B between the Chowchilla Bifurcation Structure and the new Mendota Pool bypass channel.*

Alternatives formulation builds on the Settlement goals and project-specific improvements and progresses through three stages: initial options, initial alternatives, and final alternatives.

- Initial options represent the preliminary concepts and the basic components for project implementation. They were developed based on existing information and data, studies undertaken for the Program Environmental Impact Statement/ Environmental Impact Report (PEIS/R) process, pre-appraisal level analyses and screening, as well as input from Program Work Groups, stakeholders, and the public. The initial options are described in the Initial Options TM (SJRRP 2010a).
- The initial options were refined into initial alternatives based on additional concept refinement and engineering analyses, preliminary cost-benefit analyses, additional data collection, and input from the Program, Program Work Groups, stakeholders, and the public. The initial alternatives represent a range of feasible implementation strategies incorporating appraisal-level design and analysis.
- The initial alternatives were evaluated based on the evaluation criteria and with the tools described in the Analytical Tools TM (SJRRP 2010c). The Project Description TM Attachment A – Initial Alternatives Evaluation (SJRRP 2012) documents the methods and results of the evaluation and makes recommendations for final alternatives.

2.1.5 Summary of the Alternatives Evaluation Process

A set of evaluation criteria were proposed in the Analytical Tools TM with which to evaluate the initial alternatives on the basis of flow conveyance and operations, fish habitat and passage, habitat restoration, geomorphology and sediment, groundwater, land

use, economics, and socioeconomics, and costs. The criteria were developed based on the Project goals and objectives as a means of determining whether the initial alternatives meet those goals and objectives. During the appraisal-level design, additional detail was developed for each component and structure, new and refined modeling of the river channel and floodplains was conducted, and new data from field surveys became available. The criteria were further refined based on the available data, analyses, and the level of design, and the criteria were grouped into various factors, categories, and finally implementation feasibility, benefits, and impacts perspectives.[1]

Data representing the performance of the initial alternatives according to each applicable criterion were generated and input into an evaluation matrix spreadsheet. The evaluation process leveraged concurrent data collection efforts, engineering analyses and modeling, as well as stakeholder and public input. Using the evaluation matrix, the initial alternatives were scored according to their performance at the factor, category, perspective, and overall levels allowing for an understanding of the initial alternatives with respect to the goals and objectives of the Project.

Below is a summary of the evaluation criteria. The criteria are explained in-depth in the Project Description TM, Attachment A – Initial Alternatives Evaluation, Section 6.0 (SJRRP 2012).

Objectives/Benefits Achievement

Fish Habitat and Passage

- Rearing habitat: total acres of floodplain with a depth greater than 1.0 feet at 2,500 cfs.
- Shallow Water Habitat Quality: a rating based on the proportion of very shallow water habitat (less than 0.5 feet) to the amount of rearing habitat (greater than 1.0 feet).
- Artificial structures in the migratory path: number of structures that adult salmon would need to pass. Each grade control structure, dam sill, fish passage facility (or bifurcation structure), and crossing is considered as an individual structure.
- Total number of steps at structures: the number of steps an adult salmon would need to jump or swim through. Each grade control structure, dam sill, and fish passage facility step is considered as an individual step.
- Fish screens along the migratory path: the number of fish screens with large diversion rates (greater than 100 cfs) that juvenile salmon may encounter along the migratory path.
- Potential predation sites at structures: the number of potential predation sites that juvenile salmon may encounter along the migration path. Each grade control structure, dam sill, fish passage facility (or bifurcation structure), fish screen outlet, and crossing is considered a potential predation site.

[1] Factors, categories, and perspectives are tiered groupings of the evaluation criteria. Factors are groupings of criteria, categories are groupings of factors, and perspectives are groupings of categories.

Habitat Restoration

- Wetlands and other waters of the U.S. area: the acreage of restored habitat with hydrophytic vegetation and on hydric soils.
- Sensitive vegetation alliance extent: the acreage of potential future sensitive vegetation alliances based on the Preliminary Planting Plans.
- Wildlife habitat extent: the acreage of potential future wildlife habitat types resulting from the restoration.
- Special status species habitat extent: the acreage of potential future habitat for special status wildlife species based on the wildlife habitat types.

Geomorphology

- Potential for lateral migration to impact levees: The estimated cost of providing erosion protection (revetment) on levees that may be impacted by lateral erosion.

Impacts

Groundwater

- Acres of land in which groundwater levels rise above 5-foot monitoring threshold: The acreage of land outside the proposed levee alignments that is anticipated to have shallow groundwater elevations above the 5-foot monitoring threshold and is thus subject to mitigation measures to prevent waterlogging.
- Acres of land in which groundwater levels rise above 7-foot monitoring threshold: The acreage of land outside the proposed levee alignments that is anticipated to have shallow groundwater elevations above the 7-foot monitoring threshold and is thus subject to mitigation measures to prevent waterlogging.

Land Use

- Acres of farmland removed from production: The total acres of alfalfa, almond, grapes, other row crops (grouped), palm, and pistachio that would be permanently removed from production due to the construction and long-term operation of the initial alternatives.

Socioeconomics and Economics

- Reduction in annual agricultural production values: The total production value based on unit production values and the acreage permanently removed from production due to the construction and long-term operation of the initial alternatives.

Environmental

- Wetland impacts: The estimated acreage of direct impacts to wetlands resulting from the initial alternatives.

- Sensitive vegetation alliance direct impacts: The estimated acreage of direct impacts to sensitive vegetation alliances resulting from the initial alternatives.
- Special status wildlife habitat impacts: The estimated acreage of direct impacts to special status wildlife habitat resulting from the initial alternatives.
- Historic properties potentially effected: The number of recorded historic properties identified within the extents of the initial alternatives.
- Buried deposits sensitivity: The highest buried deposits sensitivity within the extents of the initial alternatives based on the landform age scale.

2.2 Description of Alternatives

This section describes the alternatives developed for the Project. Each of the Action Alternatives consists of a floodplain width which passes 4,500 cfs, a method to bypass Restoration Flows around Mendota Pool, and a method to deliver water to Mendota Pool. Action Alternatives are considered to comply with the terms of the Settlement, substantially meet the Project goals and objectives, and have benefits potentially offsetting their impacts. Alternatives have been assessed for environmental impacts to the various resource areas (see Chapters 4.0 to 24.0).

2.2.1 NEPA and CEQA Requirements

NEPA Requirements

Reclamation, as the Project proponent and Federal lead agency, is responsible for the development of alternatives that meet NEPA requirements. For the Project alternatives, including the proposed action, NEPA requires that Federal government agencies shall (40 CFR Section 1502.14):

> *(a) Rigorously explore and objectively evaluate all reasonable alternatives, and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated.*
>
> *(b) Devote substantial treatment to each alternative considered in detail including the proposed action so that reviewers may evaluate their comparative merits.*
>
> *(c) Include reasonable alternatives not within the jurisdiction of the lead agency.*
>
> *(d) Include the alternative of no action.*
>
> *(e) Identify the agency's preferred alternative or alternatives, if one or more exists, in the draft statement and identify such alternative in the final statement unless another law prohibits the expression of such a preference.*
>
> *(f) Include appropriate mitigation measures not already included in the proposed action or alternatives.*

CEQA Requirements

CSLC, as the State lead agency, is responsible for the development of alternatives that meet CEQA requirements. Section 15126.6 of the State CEQA Guidelines requires that:

- An EIR shall describe a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project, and evaluate the comparative merits of the alternatives. An EIR need not consider every conceivable alternative to a project. Rather, it must consider a reasonable range of potentially feasible alternatives that will foster informed decision-making and public participation. An EIR is not required to consider alternatives which are infeasible.
- The range of potential alternatives to the proposed project shall include those that could feasibly accomplish most of the basic objectives of the project and could avoid or substantially lessen one or more of the significant effects.
- The specific alternative of "no project" shall also be evaluated along with its impact.
- The EIR should briefly discuss the rationale for selecting the alternatives to be discussed. The EIR should also identify any alternatives that were considered by the lead agency but were rejected as infeasible during the scoping process and briefly explain the reasons underlying the lead agency's determination…. Among the factors that may be used to eliminate alternatives from detailed consideration in an EIR are:
  - (i) Failure to meet most of the basic project objectives.
  - (ii) Infeasibility.
  - (iii) Inability to avoid significant environmental impacts.

This joint EIS/R is prepared in accordance with both NEPA and CEQA, with the Action Alternatives analyzed at an equal level of analysis (consistent with NEPA standards).

2.2.2 Overview of Alternatives

This EIS/R presents the No-Action Alternative and four Action Alternatives to implement the Project. Each Action Alternative includes the actions called for in the Settlement for the Mendota Pool Bypass and Reach 2B. Project alternatives include the following:

- No-Action Alternative.
- Alternative A (Compact Bypass with Narrow Floodplain and South Canal).
- Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative.
- Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal).
- Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal).

2.2.3 No-Action Alternative

The No-Action Alternative is required for the analysis of environmental effects according to NEPA and CEQA. Under this alternative, the Project would not be implemented. The No-Action Alternative is not consistent with the Settlement.

Existing conditions were developed for each resource area based on the availability of historical data and recent observations. Future conditions were based on reasonably foreseeable actions that would occur without the Project. The planning period for the future condition evaluation would vary depending on the resource area. The conditions under the No-Action Alternative are the conditions that are predicted to exist in the Project area during the planning period if the Project is not implemented.

No-Action Conditions

If the Project were not implemented, the components described in the Action Alternatives would not be implemented; however, the No Action Alternative assumes that other components of the SJRRP, as described in the 2012 Record of Decision, and other reasonably foreseeable actions consistent with current management direction expected to occur in the Project area, would be implemented.

The No-Action Alternative generally assumes no channel or structural improvements would be made in Reach 2B, and Restoration Flows would be reduced to not exceed the existing Reach 2B capacity. It is assumed for the No-Action condition that agriculture would continue and cropland would be the dominant cover type, consistent with the existing condition. The following assumptions about No-Action have been evaluated in the resource sections of the Project EIS/R.

Fisheries

In the No-Action Alternative, the maximum channel conveyance would be limited to the existing capacity. Fish passage improvements would not be provided at structures (Chowchilla Bifurcation Structure, San Mateo Avenue, and Mendota Dam). However, the remainder of the SJRRP would proceed, and salmon would be reintroduced into the San Joaquin River. Each spring during their outmigration, downstream migrating juveniles would be entrained in diversions from Mendota Pool and succumb to high rates of predation by non-native fish present in Mendota Pool. Adult salmon would be blocked on their upstream migration at Mendota Dam in all years except wet year types. Blocked adult salmon would be exposed to poaching in the river below Mendota Dam and poor water quality later in the year. There is no spawning substrate in Reach 3, downstream of the dam, so blocked adult fish would require alternative efforts (e.g., trap and haul) to reach spawning grounds or would not spawn successfully.

Habitat

Under the No-Action Alternative, habitat conditions in the Project area may change to the extent that Restoration Flows may recruit new vegetation in some areas. In this alternative, if Restoration Flows were to enter Reach 2B, the condition of the narrow strips of native riparian vegetation along the channel banks downstream of the San Mateo Avenue crossing would be maintained by the relatively stable water level held by

Mendota Dam. Upstream of San Mateo Avenue, riparian vegetation may recruit along the wetted channel banks unless vegetation removal is employed.

Seepage

The No-Action Alternative would maintain the existing levee alignments and heights and maximum conveyance would continue to be limited to the existing capacity. If Restoration Flows enter the existing Reach 2B, there would probably be a minimal increase in seepage from the river channel but since capacity would remain unchanged, this may be similar to the seepage experienced during Interim Flows under existing conditions. However, the SJRRP Seepage Management Plan would be implemented, and actions could be taken as part of that plan to reduce seepage effects from Restoration Flows.

Land Use, Agriculture, Economics & Socioeconomics

Under No-Action conditions, future land use in the area is unlikely to change. Reach 2B is in the unincorporated areas of both Fresno and Madera Counties. The nearest incorporated cities are Firebaugh and Mendota, both in Fresno County Population is expected to increase annually, compounded, by 1.1 percent and 1.3 percent in Fresno and Madera Counties, respectively, between 2010 and 2060 (California Department of Finance 2014). Most of that growth would likely occur in areas near the main cities in each of the counties. While population and economic projection data for specific unincorporated subareas of the counties are unavailable, neither agricultural nor non-agricultural activity is likely to expand substantially in the Mendota area.

If the Reach 2B Project is not implemented, future socioeconomic conditions in the pertinent Fresno and Madera County areas relative to conditions in other areas in the two counties would be expected to be similar. It is expected that the Reach 2B area would remain in agriculture and that most of the working population in the area would remain employed in agriculture and related industries.

Geomorphology

The No-Action Alternative would maintain the existing levee alignments and heights and maximum conveyance would continue to be limited to the existing capacity. If Restoration Flows enter the existing Reach 2B, sand transport would likely increase; however, recent sediment continuity studies have predicted that sand inputs from Reach 2A under Restoration Flows will likely result in net deposition in the upper segment of Reach 2B and potentially down to the Mendota Pool. The No-Action Alternative would not likely change the existing geomorphic conditions in Reach 2B.

2.2.4 Elements Common to All Action Alternatives

Action Alternatives would be designed to provide:

- Conveyance of at least 4,500 cfs in Reach 2B and through the Mendota Pool Bypass.
- Diversion of up to 2,500 cfs from Reach 2B into Mendota Pool.

Additionally, some constructed elements are also common to all Action Alternatives. Those elements are described below.

Fish Habitat and Passage

The amounts of fish habitat and the number of structures fish would need to pass vary among the Action Alternatives; however, some conditions and criteria are consistent across alternatives and warrant discussion here.

One of the primary focuses of the Action Alternatives is to provide floodplain and riparian habitat to provide benefit to migrating juvenile and adult salmonids and other native fishes. Floodplain and riparian habitats in the Action Alternatives would include a variety of native plant communities suited to the hydrology, soils, and climate of Reach 2B and the San Joaquin Valley.

The Action Alternatives also include provision of fish passage at structures for salmonids and other native fish. These structures vary by alternative but overall include fish screens, fish passage facilities, grade control structures, and bifurcation structures (under certain flows). The designs for structures with fish passage components would be based on criteria in *Anadromous Salmonid Passage Facility Design* (NMFS 2008) and *Guidelines for Salmonid Passage at Stream Crossings* (NMFS 2001). Specifically, the Action Alternatives would provide suitable hydraulic conditions for passage of up-migrating adult salmonids, out-migrating juvenile salmonids, and inter-reach migration of other native fish between Reach 2A and Reach 3. Suitable hydraulic conditions include those conditions which the species is physically capable of passing and do not cause undue stress on the animal. The passage features would be designed to cause no physical harm to fish. The design criteria are structured around the life stages of the target anadromous species and the timing of the runs for upstream movement of adult fall and spring run Chinook and winter steelhead and the downstream movement of juvenile life stages spawned from these runs. Recommended criteria are based on a combination of swimming ability of the fish species as reported in scientific papers and criteria in agency design guidelines. Recommended design criteria to provide for successful fish passage (depth of flow, suitable velocity ranges and jump height) are provided in Table 2-1. The design criteria for a particular species would be met over the associated flow range (minimum flow to maximum flow).

Table 2-1.
Fish Passage Design Criteria

Species	Life-stage	Migration Timeframe	Frequency	Minimum Flow	Maximum Flow	Maximum Velocity [1]	Minimum Water Depth [2]	Maximum Jump Height [3]	Minimum Pool Depth
			years	cfs	cfs	fps	feet	feet	feet
Chinook salmon	Adult	Spring and fall pulse	All years except CL	115 [4]	4,500	4.0	1.2	1.0	[5]
	Juvenile (downstream)	Nov-May	All years except CL	85 [7]	n/a	n/a	1.0	n/a	[5]
Steelhead	Adult	Spring and fall pulse	All years except CL	115 [4]	4,500	4.0	1.2	1.0	[5]
	Juvenile (downstream)	Nov-May	All years except CL	85 [7]	n/a	n/a	1.0	n/a	[5]
Sturgeon	Adult	Spring pulse	W and NW years	1,138 [8]	4,500	6.6	3.3	None – swim through	n/a
Lamprey	Adult	Spring pulse	All years except CL	125 [6]	4,500	[9]	[9]	[9]	n/a
Other native fish	Adult	Spring pulse	W, NW, and ND years	543 [10]	4,500	2.5	1.0	None – swim through	n/a

W = wet; NW = normal wet; ND = normal dry; CL = critical low

[1] Recommended maximum velocities shown are for grade control structures or structures with short longitudinal lengths based on *Anadromous Salmonid Passage Facility Design* (NMFS 2008) and *Guidelines for Salmonid Passage at Stream Crossings* (NMFS 2001). For structures with longer lengths (e.g., culverts and bifurcation structures under certain conditions), maximum velocities would be developed based on criteria in *Anadromous Salmonid Passage Facility Design* (NMFS 2008) and *Guidelines for Salmonid Passage at Stream Crossings* (NMFS 2001).

[2] Minimum water depth criteria based on 1.5 times body depth or 1 foot depth, whichever is greater based on *Anadromous Salmonid Passage Facility Design* (NMFS 2008) and *Guidelines for Salmonid Passage at Stream Crossings* (NMFS 2001).

[3] Maximum jump height criteria based on criteria in *Anadromous Salmonid Passage Facility Design* (NMFS 2008) and *Guidelines for Salmonid Passage at Stream Crossings* (NMFS 2001).

[4] Based on Exhibit B lowest flow in the fall spawning period (starts Oct 1) for the desired frequency; all Spring Pulse Flows are higher.

[5] Pool depths to be based on criteria in *Anadromous Salmonid Passage Facility Design* (NMFS 2008) and *Guidelines for Salmonid Passage at Stream Crossings* (NMFS 2001).

[6] Based on lowest flow within Exhibit B Spring Pulse Flow period for the desired frequency.

[7] Based on lowest flow within desired migration period for the desired frequency.

[8] Wet and normal wet years constitute 50% of years in the historical record. Based on an analysis of varying Restoration Flows management strategies (SJRRP 2010d); flows with a 50% exceedance could range from 1,138 to 4,500 cfs.

[9] Lamprey designs to be based on criteria in *Best Management Practices for Pacific Lamprey* (USFWS 2010)

[10] Wet, normal wet, and normal dry years constitute 80% of years in the historical record. Based on an analysis of varying Restoration Flows management strategies (SJRRP 2010d); flows with an 80% exceedance could range from 543 to 4,500 cfs.

The Action Alternatives include facilities that fish would encounter or need to pass to migrate between Reach 3 and Reach 2A (from downstream to upstream). The need for fish screens at diversion facilities will be further evaluated as Project planning and design continues. The following fish screens are included in the Action Alternatives in the event that they are determined necessary: the Lone Willow Slough fish screen (see Section 2.2.4), Big and Little Bertha pumps screens, and screens on other smaller diversions. Each alternative includes other facilities specific to that alternative. Each structure represents a potential stressor for adult salmon and potential predation site for juvenile salmon. However, each structure would be designed to perform according to fish passage and screening design criteria. In addition, the channel and floodplain elements of the Action Alternatives incorporate riparian areas to provide cover, woody material, and velocity variability, while the design footprint allows sufficient space to accommodate channel structure variability, all of which may help to reduce stress and predation.

During construction, impacts to fish would be minimized by including some or all of the following measures:

- Temporary bypass facilities around construction areas that meet fish passage criteria.
- Construction in the dry (i.e., not in active flows).
- Phased construction that would allow passage to continue in the channel or in the completed portions of structures while other portions are built.
- Fish rescue and relocation.

Levees

The location, length, and height of the levees vary among the Action Alternatives; however, some design criteria and features would be consistent across alternatives and warrant discussion here.

Levees would be required along the Project area to contain Restoration Flows. While the height and footprint of the levees vary according to their location along the channel and the ground elevation, the capacity, freeboard, and cross-section would be consistent. Localized backwater and redirection effects at Project structures would be considered during design of levee heights. Levees would be designed to maintain at least 3 feet of freeboard on the levees at 4,500 cfs. Levee design would be based on the U.S. Army Corps of Engineers (Corps) *Engineer Manual 1110-2-1913-Design and Construction of Levees* guidelines (Corps 2000a) and *Engineer Manual 1110-2-301 Guidelines for Landscape Planting and Vegetation Management at Floodwalls, Levees, & Embankment Dams* (Corps 2000b). The design includes seepage control measures, inspection trenches, maintenances roads, and drainage trenches to direct off-site drainage.

Levee alignments maintain a 300-foot buffer zone, where appropriate, between the levee and river channel to avoid impact to levees over time due to potential channel migration. In areas where a minimum 300-foot buffer zone between the main river channel and levee cannot be maintained, bank revetment would be incorporated in the design.

New levees would be designed to have sideslopes of 3 horizontal to 1 vertical (3H to 1V) on the waterside and landside. A maintenance road and surface drainage ditch would also be included. Surface drainage ditches would only be intended to capture and direct runoff; they are not intended to address groundwater seepage or through-levee seepage. By following the Corps standards, all levees would have an inspection trench. Additional data collection and analysis would be required to verify the groundwater conductivity rates of the *in situ* and borrow soils and to finalize the design of seepage control measures.

The levee alignments shown on the plan views of the Action Alternatives may be adjusted during final design. Adjustments may be made for several reasons, including to improve flow conditions on the floodplain, to improve habitat conditions on the floodplain, to reduce potential erosion, to accommodate adverse soil conditions, and to avoid existing infrastructure among others. The final levee alignments will be within the impact areas evaluated in this document.

Seepage Control Measures

Seepage of river water through or under levees is a concern for levee integrity and adjacent land uses. Through-seepage, water that seeps laterally through the levee section, would be addressed through proper levee design and construction (e.g., selection of low porosity materials and proper compaction). Under-seepage, water that seeps laterally by travelling under the levee section, is primarily controlled by the native soils beneath the levee and seepage control measures would be included where native soils do not provide sufficient control. Seepage control measures would be included, as necessary, in the Project in areas where under-seepage is likely to affect adjacent land uses. Seepage control measures could include: cut-off walls, interceptor drains or ditches, seepage wells, seepage berms, land acquisition (fee title or seepage easements) and other measures that can be implemented within the Project area.[2]

Borrow

Borrow material would primarily be required for the construction of the levees, but it may also be used in the construction of other structures for foundation or backfill material. Levees may be constructed entirely of local borrow material, a mix of local and imported borrow material, or just imported borrow material. Borrow locations will be determined after a geotechnical exploration of the local borrow areas is complete; the exploration will determine the suitability of local soils for use as borrow material. Until the exploration can be complete, it is assumed that all levee fill will come from local borrow sites. Investigation and analysis of potential borrow sites is ongoing by SJRRP, and the borrow area information will be updated as new information becomes available.

[2] A cut-off wall is a construction technique to reinforce areas of soft earth that are near open water or a high groundwater table with a mixture of soil, bentonite, and cement. Interceptor drains are buried perforated pipes and interceptor ditches are surface ditches, both of which intercept groundwater and redirect it to a discharge point. Because the drains and ditches have lower resistance to flow, the groundwater table can be kept artificially low in areas near the pipe or ditch. The discharge point could include a lift pump to move drained water over the levees, or it could be discharged directly to a surface water body (e.g., agricultural canal). Seepage wells are groundwater wells that are used to pump and draw down the water table where seepage is occurring. Seepage berms are berms placed on the landside of a levee to add additional weight and width to the levee to counteract seepage.

Topsoil from local borrow areas would be stockpiled for reuse at the borrow site or within the Project area.

The locations of borrow areas are dependent on the locations of suitable materials. To the extent that suitable materials and the locations for floodplain grading coincide, borrow from those areas may be preferred. Borrow from within the Project levees will be designed to be compatible with native fish habitat and uses by either reconnecting to the river channel or by restoring to an appropriate elevation to prevent stranding.

It is estimated that up to 350 acres of land total will be needed for borrow areas. This includes borrow locations inside and outside the Project levees (identified as Potential Borrow Area on Figure 1-2). Borrow areas will avoid sensitive biological resources to the extent practicable.

Levee and Structure Protection

Action Alternatives generally provide a minimum 300-foot buffer between the existing channel and the proposed levee, where appropriate and feasible. For locations where the 300-foot buffer was not included, erosion protection for the levee in the form of revetment would be included. The revetment would be riprap material covered by soil and then planted to provide a vegetated surface. However, softer approaches, such as bioengineering or dense planting, may be considered during design depending on velocities and scour potential. Locations that require revetment include areas where the 300-foot buffer was not included due to the proximity of existing infrastructure, near the proposed structures, and along river bends less than 300 feet from the levee in areas that have the potential to erode, as determined in the design process.

Channel Bank Protection

Action Alternatives could include riparian vegetation, rock vanes, woody materials, revetment, or other measures designed to protect channel banks from erosion. Bank protection measures would be installed in locations susceptible to and likely to experience bank erosion.

Removal of Existing Levees

Removal of portions of the existing levees is included and designed to expand the inundation area of the floodplain out to the proposed levees and improve connectivity between the river channel and proposed floodplain. The locations of existing levee removal would be based upon the hydraulic performance of the channel and floodplain. In certain locations, however, highly desirable existing vegetation (native and sensitive vegetation communities that can serve as seed banks for future vegetation communities) can be found on the existing levees. Where hydraulic performance and connectivity of the floodplain would not be negatively affected, portions of the existing levees with highly desirable vegetation would remain in place. Materials that are removed from the existing levees would likely be reused within the Project area.

Floodplain and Channel Grading

Floodplain and channel grading would be included with the Action Alternatives. Floodplain and channel grading would include any or all of the following at locations to be determined during design:

- Creating high-flow channels through the floodplain to increase the inundation extent at lower flows.
- Connecting low-lying areas on the floodplain to the river to prevent stranding.
- Removing high areas where flow connectivity would be impeded (e.g., farm road grades).
- Excavating floodplain benches adjacent to the river channel to increase the frequency of inundation.
- Creating greater inundation depth diversity on the floodplain.
- Excavating channels in portions of the Project area to tie into existing elevations upstream and downstream of the Project or to create desirable sediment transport conditions.

Floodplain and channel grading can provide benefits to salmon and other native fish by allowing inundation to occur at lower flows, by distributing suitable rearing habitats further into the floodplain, by connecting rearing habitat to primary production areas (shallow water habitat), by providing escape routes during receding flows, and by confining flows to a deeper, narrower channel to limit temperature increases.

Figure 2-3 provides an example of how various floodplain grading approaches can be used to expand inundation on the floodplain. The Existing Channel graphic shows an example of how inundation would occur without floodplain grading. The Lowered Floodplain example shows an example of how floodplain benches, lowered areas to either side of the channel, could be used to inundate floodplain areas at lesser flows. This graphic also shows how lowered floodplains could affect inundation at moderate flows. The High Flow Channels graphic shows an example of how high flow channels, side channels that initiate at larger flows than the main channel, could be used to expand floodplain inundation.

Lone Willow Slough Fish and Riparian Diversions Screens

Lone Willow Slough connects to the river at approximately River Mile (RM) 215.9 just downstream of the Chowchilla Bifurcation Structure. Some Action Alternatives include construction of a fish screen at this diversion, if determined necessary. During flood control releases from Friant Dam and when the Exchange Contractors are exercising their water rights on the San Joaquin River, in lieu of taking substitute water from the Delta-Mendota Canal, up to 125 cfs of water may be diverted for irrigation from Reach 2B into the Lone Willow Slough. A screen would prevent fish from entering the canal when flows are being diverted. The fish screen structure would consist of a 15-foot by 21-foot concrete hollow box, with the river side of the box open to river flows and the back of the box fitted with a board guide to control diversion into the irrigation canal. The opening at the riverside would include an automated cleaner system, trash rack and a fish screen to

prevent migrating fish from entering the intake. The screen would be designed to meet *Anadromous Salmonid Passage Facility Design* (NMFS 2008) criteria.

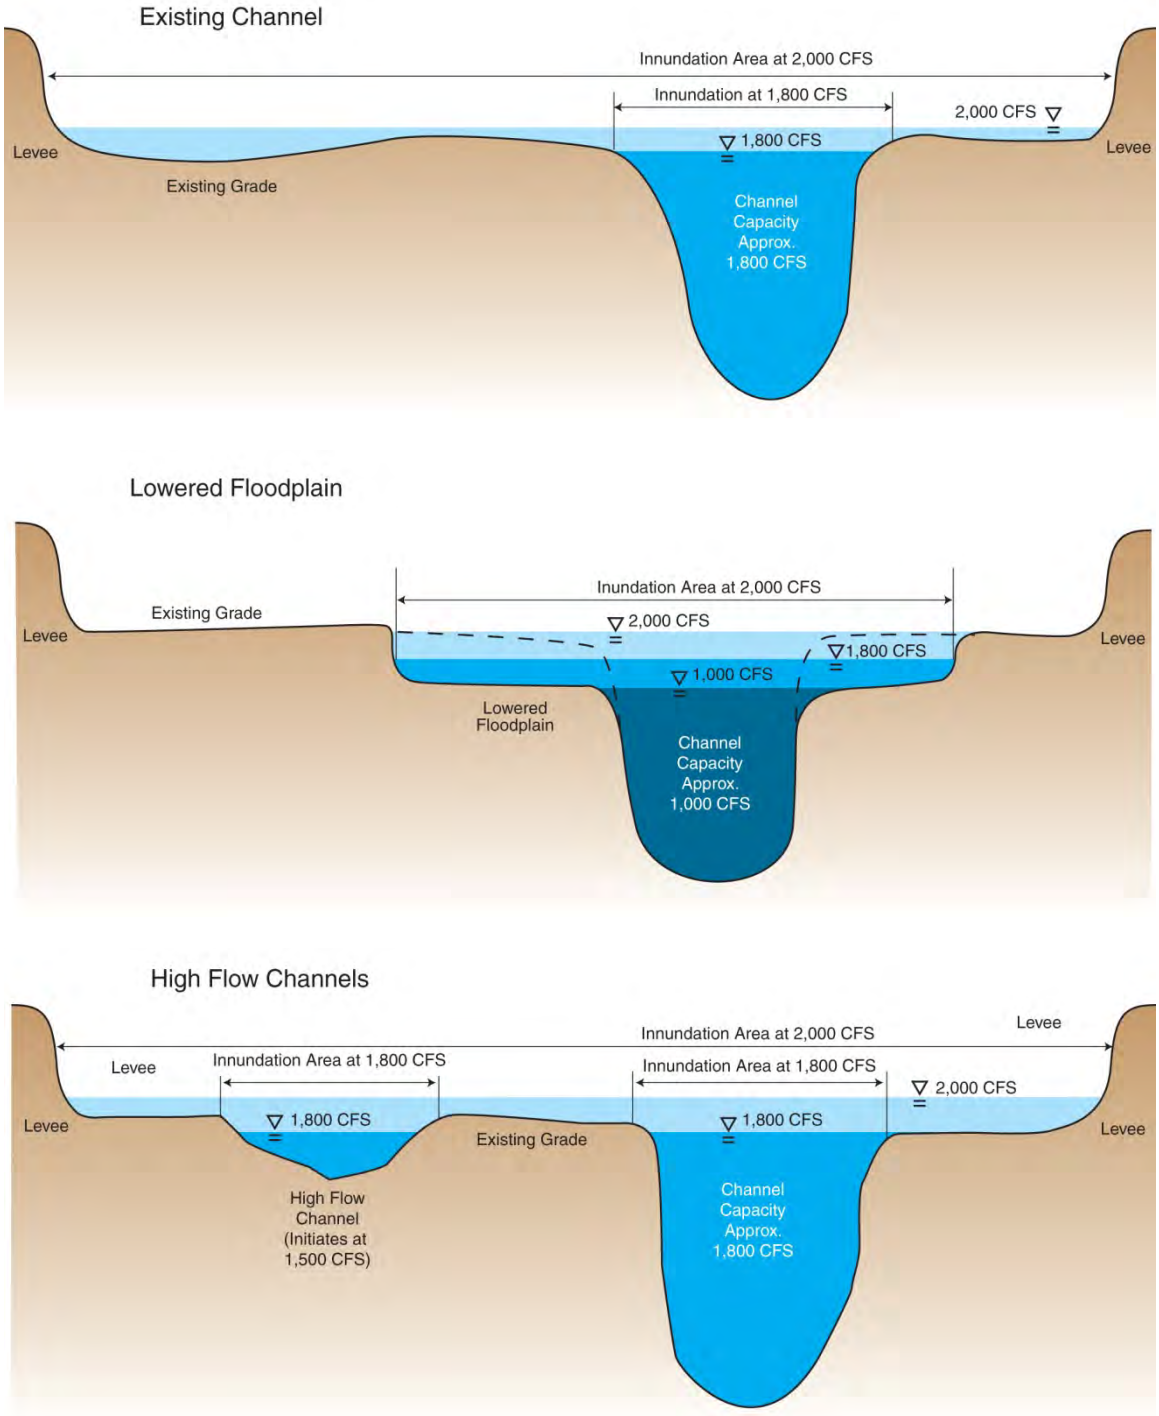

Figure 2-3.
Example Floodplain Grading Approaches

There are existing diversion pumps located along Reach 2B (e.g., Big and Little Bertha pumps). These pumps would be retrofitted with fish screens, where required, to prevent migrating fish from entering the intakes. The screens would be designed to meet *Anadromous Salmonid Passage Facility Design* (NMFS 2008) criteria.

Infrastructure for Fish Monitoring

The designs for control structures, fish passage facilities, and fish screens include security fences and gates, mounting hardware, and electrical supply in order to conduct fish monitoring activities. Construction, operations, and maintenance of the fish monitoring infrastructure are included as part of this Project. The fish monitoring activities themselves are not included in this Project, and will be addressed in subsequent environmental analysis, as appropriate.

Existing Infrastructure Relocations or Floodproofing

Existing infrastructure (see Figure 2-4) such as groundwater wells, pumps, electrical and gas distribution lines, water pipelines, and canals is located in the Project area and would require relocation, retrofitting, or floodproofing to protect the structures from future Restoration Flows and increased floodplain area. Although the relocations, retrofits, and floodproofing would be included as part of the Project; the actual relocation, retrofit, or floodproofing work may be performed by others. As a result of the Project, some existing infrastructure may be unnecessary in the future (e.g., power lines that service pumps relocated to outside the Project area). In these cases, infrastructure may be demolished or abandoned in place.

Electrical and Gas Distribution

The length of electrical and gas distribution line identified for possible relocation was evaluated for the Action Alternatives. Information from Pacific Gas & Electric (PG&E) was available for portions of the area in GIS shapefile format and was supplemented by field data. At the current level of design, it was assumed that the length of existing electrical and gas distribution line found within the Project area would need to be replaced.

Canals and Drains

The length of canals identified for possible relocation was evaluated for the Action Alternatives. On-farm canals and drains visible on the LiDAR imagery (Central Valley Floodplain Evaluation and Delineation [CVFED] 2009) and identified during on-site field meetings with landowners were quantified. No canal and drains outside the Project footprint have yet been identified for redesign. Some portions of canals and drains could be discontinued in the future; the extent of discontinued and replaced canals will be considered during landowner negotiations. No subsurface drains were able to be quantified; however, some are believed to exist within the area.

Lift Pumps

The number of lift pumps identified for possible relocation was evaluated for the Action Alternatives. Lift pumps visible on the LiDAR imagery (CVFED 2009) or noted in the CalFish Passage Assessment Database (CalFish 2014) were assumed to require relocation to new facilities on the edge of the proposed levees. A pilot channel dug from the low

flow river channel to the intake of the relocated pumps was also assumed. Locations in the CalFish Passage Assessment database were confirmed using the LiDAR imagery when possible.

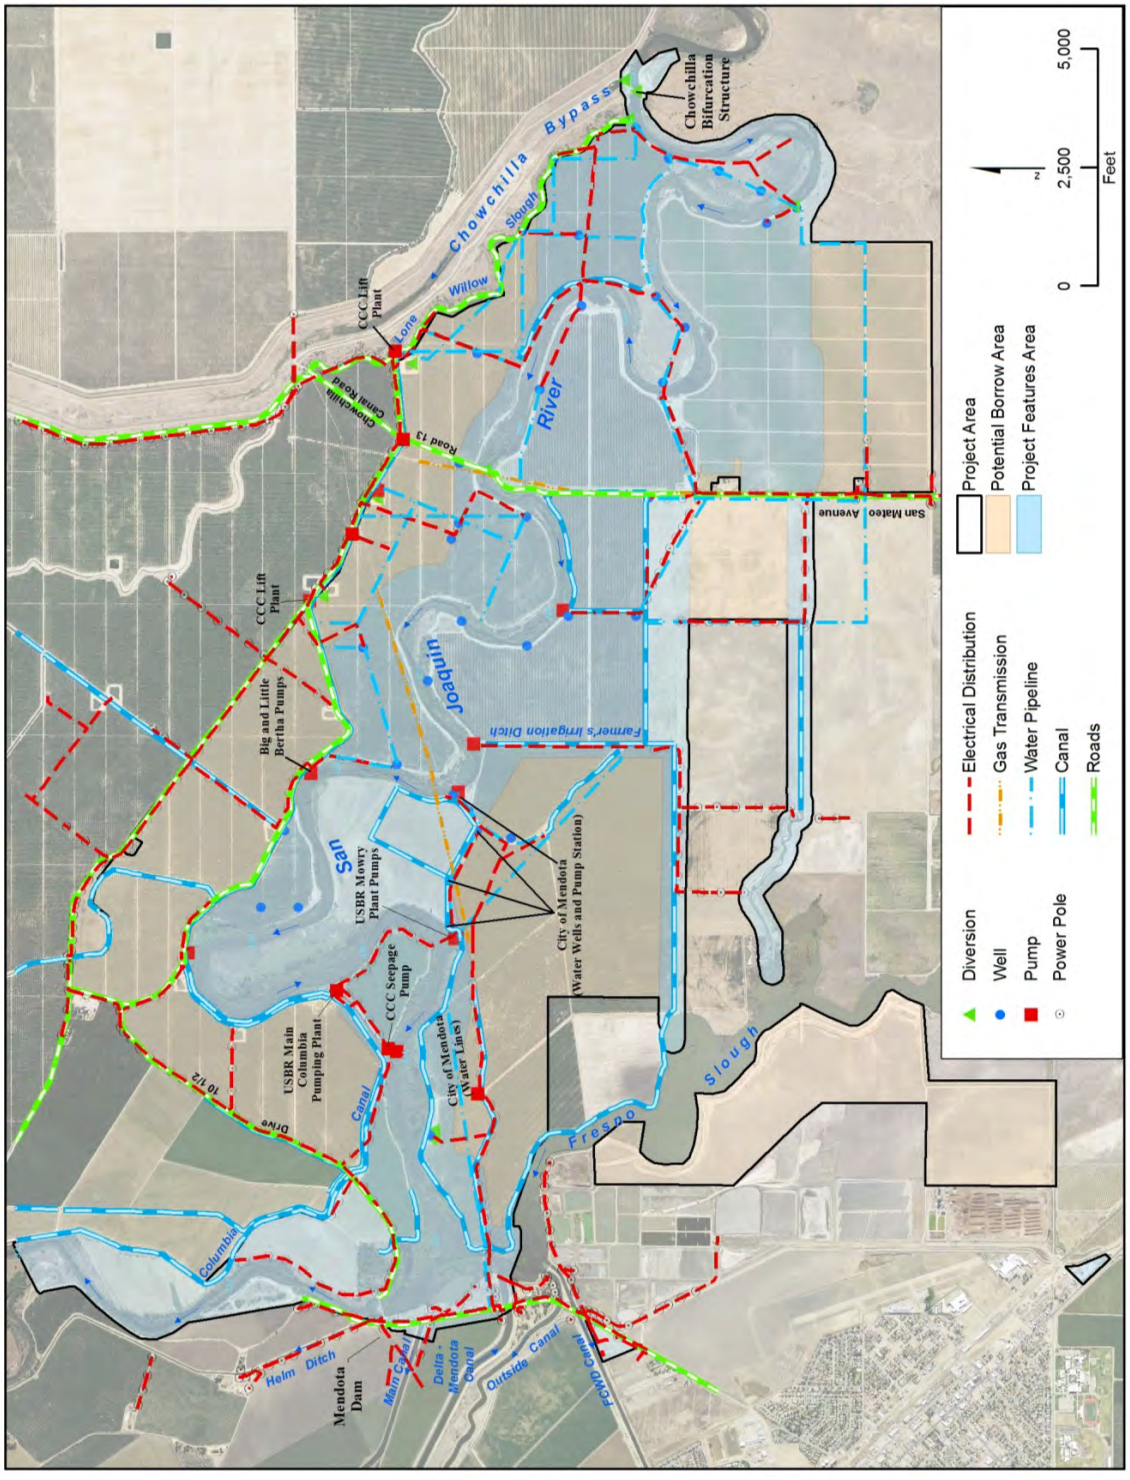

Figure 2-4.
Existing Infrastructure in the Project Area

Groundwater Wells

The number of existing wells identified for possible floodproofing or relocation, including the city of Mendota groundwater wells, was evaluated for the Action Alternatives. Wells were identified within the area using aerial photography. During design, the DWR wells database would be consulted for an estimate of abandoned wells that have not been destroyed, so that these old wells would not be conduits for flood waters to the groundwater. A formal well canvas would also be conducted. Floodproofed wells would be provided with year-round vehicular access via a raised roadbed across the floodplain. The roadbed could include multiple culverts to support floodplain connectivity, depending on the length of the access road and its effect on floodplain flows. Wells relocated by the Project would provide equal utility. Wells taken out of service by the Project would be abandoned in accordance with U.S. Environmental Protection Agency (EPA), DWR and/or local regulations.

Regulating Reservoirs

The number of irrigation regulating reservoirs identified for possible relocation was evaluated for the Action Alternatives. Reservoirs were assumed to be a typical size, contain one lift pump, and half of the reservoir located below the surrounding grade and half above the surrounding grade.

Oil and Gas Wells

Two closed or active oil and gas wells have been identified within the Project area for potential closure, relocation, or buyout. If active oil and gas wells cannot be avoided, the destruction or closure of those wells would be conducted in accordance with the California Department of Conservation, Division of Oil, Gas, and Geothermal Resources (DOGGR) regulations.

Other Utilities

Other infrastructure was identified within the impacted areas. Other facilities include: high voltage transmission lines, gas lines, and water pipelines. High voltage transmission lines are assumed to be high enough to not be impacted. Gas lines are typically attached to bridges or buried below the river when crossing the river and were assumed not to require relocation. Water pipelines were quantified from existing maps and discussions with landowners. Water pipelines may be relocated or abandoned depending on their future use requirements. Service line crossings (e.g., gas, water, electrical) would be considered during levee design.

Construction Access

Access for vehicles carrying materials, equipment, and personnel to and from the construction area would be provided via several existing roadways in the Project vicinity (see Figure 2-5). Improvements may be required to upgrade roadways, pavements, and crossings for anticipated construction traffic and loads, provide adequate turning radii and site distances, and to control dust on non-paved roads. Anticipated improvements include:

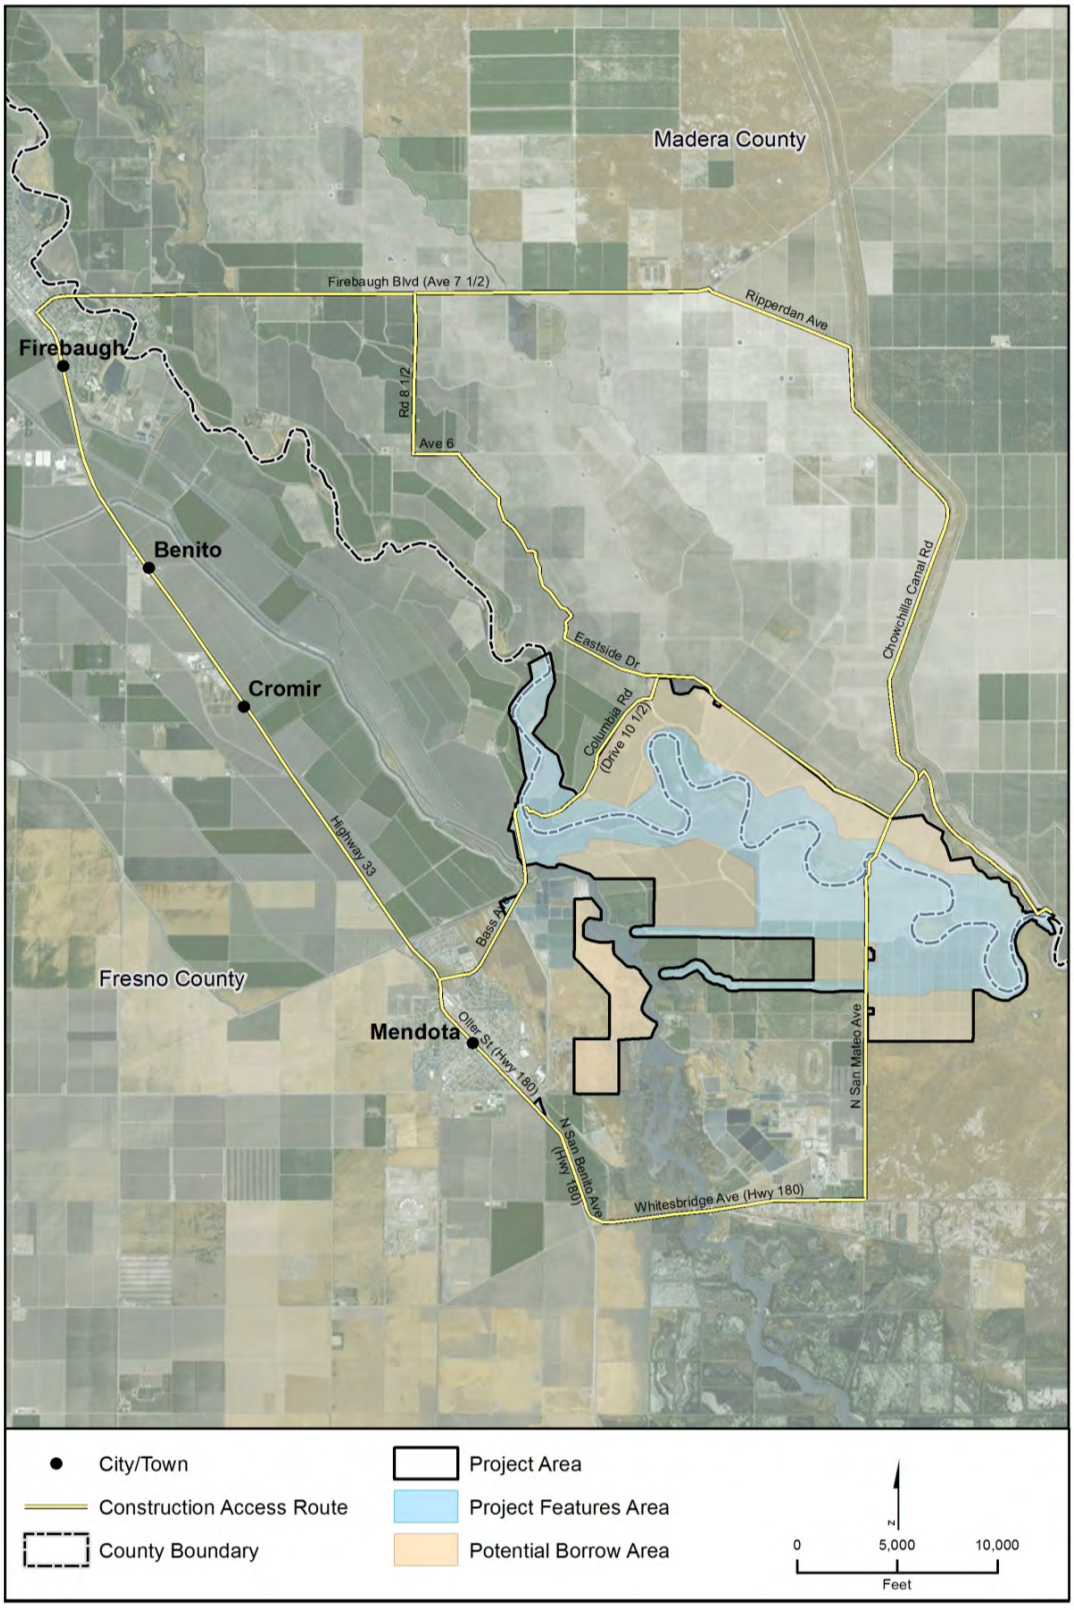

Figure 2-5.
Construction Access Routes

- Eastside Drive – Approximately 0.6 mile of dirt road starting at Road 10 ½ will likely require overlaying, and the implementation of dust control measures.
- Chowchilla Canal Road/Road 13 – Approximately 0.3 mile of road starting at Eastside Drive will likely require some overlaying and the implementation of dust control measures.
- San Mateo Avenue – Approximately 0.5 mile of gravel and 1.5 miles of oil-dirt road starting at the existing San Joaquin River levees will likely require some overlying and the implementation of dust control measures.
- Bass Avenue Canal Crossings – These crossings may need additional bracing and shoring to ensure that they will be able to support the load of the construction equipment and activities. All the construction equipment on Bass Avenue will be within the legal loads (see note below). This crossing is on the Fresno County replacement list.
- Delta-Mendota Canal Crossing – This crossing may need additional bracing and supports to ensure that it will be able to support the load of the construction equipment activities.

Dust control measures for non-paved roads could include the use of water trucks or dust palliative for dust control or gravel placement where necessary. Legal loads would be used on all roads, and once construction is completed, the roads would be returned to the same condition as they were prior to the Project.

Revegetation of Temporary Disturbance Areas

Areas temporarily disturbed during construction would be restored to their previous contours, if feasible, and then seeded with a native vegetation seed mixture to prevent soil erosion. Some areas, such as borrow areas, may not be feasible to restore previous contours, but these areas would be smoothed and seeded.

Operations and Maintenance

The Project includes long-term operations and maintenance of the proposed facilities and features as described below.

Maintenance

Levees will require maintenance for vegetation management, access roads, levee inspections, levee restoration, rodent control, minor structures, encroachment removal, levee patrolling during flood events, and equipment. Levee vegetation management includes equipment to drag or mow the levee banks or aquatic-safe herbicide applications. Maintenance of access roads includes replacing gravel or scraping and filling of ruts to keep the roads in good condition. Levee restoration includes restoring areas with erosion or settlement problems or adding armor. Rodent control includes setting traps with bait and periodically checking the traps. Minor structures maintenance includes repair or replacement of gates, locks or fences. Encroachment removal involves removing illegally dumped materials.

Floodplain maintenance includes vegetation management for invasive species, periodic floodplain and channel shaping to retain capacity and prevent fish stranding, and other

floodplain maintenance activities such as debris removal and repair of channel banks and bank protection measures.

San Mateo Avenue maintenance includes maintenance when flows overtop the road and annual maintenance to keep the crossing functional and ensure that it can meet fish passage requirements. These maintenance activities include cleaning the culverts of debris or sediment, clearing any debris from the roadway prior to opening after flows have receded, repairing the road sub-base, base, and gravel surfacing, and repairing or replacing minor structures. Minor structures maintenance includes replacing gate locks, painting gates, replacing lost or damaged signage, and lubricating gates.

Control structures and Fresno Slough Dam maintenance includes annual operating maintenance for control gates, lubricating the fittings, greasing and inspecting the motors, replacing parts and equipment, in-channel sediment removal in the structure vicinity, and cleaning the trash rack. Work needed for the radial gates includes inspection of gates and seals and periodic replacement of seals. Work needed for the trash rack includes periodic repair or replacement of components, inspecting for operation, and greasing and inspecting the motors.

Fish screen maintenance is needed to ensure that screens are functioning to NMFS standards and capable of diverting the required flow. Fish screens maintenance includes removing the screens for cleaning, replacing screens when needed, periodic repair or replacement of brush cleaning system components, periodic repair or replacement of trash rack components, inspection for operation, greasing and inspecting motors, and in-channel sediment removal in the structure vicinity.

Fish barrier maintenance is needed to ensure that the barrier is functioning to NMFS standards and capable of passing the required flow. Fish barrier maintenance includes periodic repair or replacement of screens, in-channel sediment removal in the structure vicinity, and debris removal.

Fish passage facility maintenance is needed to ensure that the passage facility is functioning to NMFS standards. Depending on the type of fish passage facility built, fish passage facility maintenance could include removing sediment and debris from the facility, in-channel sediment removal in the structure vicinity, inspection of gates and seals and periodic replacement of seals, periodic repair or replacement of weir gates, periodic repair or replacement of supplementary water system components, inspection for operation, greasing and inspecting motors, and replacement of riprap, grouting, boulders, large woody debris, or other “natural” features of the fish passage facility.

Seepage control measure maintenance is dependent on the type of measures implemented but could include activities such as periodic sediment removal and channel re-shaping for interceptor ditches, cleaning or flushing of interceptor drains, repair and replacement of pump parts for seepage wells and lift pumps, and vegetation management, berm restoration, and rodent control for seepage berms.

Levee and structure protection maintenance includes repair restoration of protection measures due to erosion or degradation and vegetation management.

Water diversion canal maintenance includes sediment removal and channel re-shaping.

Mendota Dam maintenance includes periodic minor upstream sediment removal in order to operate the Short Canal only.

Maintenance Schedule

All maintenance activities, when possible, would be timed to minimize the impacts to fish. Access and safety concerns are the main driver for timing of the maintenance activities, but can be scheduled around fish migration. Ultimately, the schedule may be impacted by compliance with the clearance to conduct the work and timing of flows.

Maintenance of levees and floodplains with aquatic-safe herbicide treatment would occur sometime between spring and fall and would depend on the plant species that are being treated. Typically the herbicide would be administered prior to the plant going to seed and may need to be sprayed more than once. Disking for vegetation management usually occurs twice within the year; once in early spring after the rainfall season and then again in late summer prior to plants going to seed. Access road and levee restoration work would likely be done in the summer after the rainfall season, and timing and projects would be dependent on environmental clearance for small mammals, nesting birds or burrowing owls, and other wildlife species. Rodent control would likely be done by a pest control advisor and would likely be done in the spring through fall and not during the rainfall season. All levee and floodplain work can be impacted by the presence of nesting birds, so in some areas work may not begin until the nesting birds have fledged or if there is some other biological reason to believe that the maintenance activities would not impact the nesting birds.

Timing of the maintenance of structures within the waterways would depend on the flow hydrograph and forecasted flows, but can typically be expected in the summer/fall after high spring flows have receded. Cleaning of the in-channel structures would typically occur when flows are low enough to allow crews and equipment to enter the river safely to access the structures. San Mateo Avenue may be cleared or repaired earlier for access as soon as flows recede and are not likely to increase for the remainder of the water year. If earlier, this work would only be for road access and would not be located in the channel itself.

Debris that collects on trash racks, screens, ladders, or other fish passage structures will need to be periodically removed but will likely be scheduled based on the operation permits for these structures. Annual maintenance cleaning would be expected after the fish migration, but will need to be timed when flows have receded.

Lubing and annual gate maintenance would likely be in the late summer or early fall prior to winter and spring flows to make sure the structures are operating properly and to provide time for repairs and ordering parts if needed.

For the Short Canal Option, the boards would be placed back into Mendota Dam. This could occur at any time, but would likely occur during the irrigation season (typically March through October). The fish passage structure at the dam would allow for fish passage when the boards are in-place.

Water diversion canals that require maintenance could be isolated from the river system by closing the headgates at the canals which will not impact fish migration.

Operations

There are no operations for levees, floodplains, or levee and structure protection.

San Mateo Avenue operations include closing the gates to the crossing during high flows and reopening once flows have receded.

Control structures and Fresno Slough Dam operations include operating the motors for the control gates, inspecting and assessing the gates, adjusting the gates for various stages of flows, and running the automatic trash sweep.

Fish screen operations could occur every day when diversions are occurring. Operations include visually inspecting screens, verifying flow, clearing obstructions and debris, adjusting the baffles, permitting and regulatory compliance measures, estimating performance (i.e., velocity measurements), powering the screen, running the pumps for the sediment removal system, running automatic brush cleaning and trash rake motors, and running pumps for the fish diversion pipe. Operations also could include methods to reduce predation of juvenile fish (e.g., noise systems to scatter predators, netting, and periodic draining of the screen return pipes) and may include the addition of juvenile and/or adult fish traps.

Fish barrier operations could occur every day during salmon upmigration for spawning. Operations include visually inspecting screens, verifying flow, clearing obstructions and debris, installing and removing barrier screens, and permitting and regulatory compliance measures.

Fish passage facility operations could occur every day during fish migration. Operations include visually inspecting the facility, verifying flow, clearing obstructions and debris, adjusting the weirs, permitting and regulatory compliance measures, estimating performance (i.e., velocity measurements), powering mechanically controlled weirs.

Seepage control measure operations are primarily passive, but seepage well operations would include running the pumps to lower the water table, and interceptor drain and ditch operations could involve running lift pumps.

There are no operations for the water diversion canal. Operation of the canal headworks is covered under control structures above.

Mendota Dam operations include placing and removing stop logs in order to operate the Short Canal (only applies to Alternative C [Fresno Slough Dam with Narrow Floodplain and Short Canal]; see Section 2.2.7).

Monitoring Activities

Monitoring activities would include physical and nonphysical activities within the Project area. Several monitoring components would be covered by the Program's *Physical Monitoring and Management Plan* (PEIS/R pages 2-49 to 2-52, and Appendix D.1, SJRRP 2011a), which provides guidelines for observing conditions as well as adjusting to changes in physical conditions within the Project area. The Program's *Physical Monitoring and Management Plan* consists of multiple component plans, addressing physical conditions such as flow, groundwater seepage, channel capacity, and propagation of native vegetation. Each component plan identifies objectives for the physical conditions within the Project area, and provides guidelines for the monitoring and management of those conditions. The component plans identify potential actions that could be taken to further enhance the achievement of the objectives. Finally, the Plan includes a description of monitoring activities which apply to one or more of the component plans. The component plans include the following monitoring objectives, all of which are identified in the Program's *Physical Monitoring and Management Plan*:

- **Flow** – To ensure compliance with the hydrograph releases in Exhibit B of the Settlement and any other applicable flow releases (e.g., buffer flows) (detail is provided in the Program's *Restoration Flow Guidelines*).
- **Seepage** – To reduce or avoid adverse or undesirable seepage impacts (detail is provided in the Program's *Seepage Management Plan*).
- **Channel capacity** – To maintain flood conveyance capacity (detail is provided in the Program's *Channel Capacity Report*).
- **Native vegetation** – To establish and maintain native riparian habitat.

Project specific components of the monitoring will include addressing effectiveness monitoring of fish screens and fish passage at structures within the Project area. The monitoring objective is the following:

- **Passage and screening effectiveness** – To maintain effective fish passage and fish screening at structures and diversions.

Monitoring activities, as they are described in the Program's *Physical Monitoring and Management Plan*, are guidelines for monitoring and could change during Project implementation. Monitoring activities in Reach 2B could include the following Program-level activities:

- **Flow monitoring** – Flow, cross sections, and surface water stage at gaging stations, and at additional locations during high-flow events.
- **Groundwater level monitoring** – Groundwater elevation in monitoring wells (detail is provided in the Program's *Seepage Management Plan*).
- **Aerial and topographic surveys** – True color aerial photographs and topographic surveys to assess river stage, hydraulic roughness, river width, bed elevation, and vegetation conditions.

- **Vegetation surveys** – Surveys of seed dispersal start and peak times, and native riparian vegetation establishment.
- **Sediment mobilization monitoring** – Sediment mobilization, bar formation, and bank erosion through aerial and topographic surveys of areas with elevated erosion potential (detail is provided in the Program's *Sediment Management Plan*).

Project specific monitoring activities will include the following:

- **Passage and screening effectiveness** – Flow, cross-sections, water surface, and velocity measurements near and within structures that provide passage or screening. Fish counting devices and rotary screw traps to count and measure fish passage and fish size.

Structure Design and Subsidence

All design work would be completed in general accordance with Reclamation Design Standards, applicable design codes, and commonly accepted industry standards. Where design criteria are missing for a specific project element, either Reclamation would be consulted for design specifications or standard engineering practice methods would be employed.

In addition, ground subsidence effects are anticipated to be experienced in the Project area. During the design process, causes of the observed subsidence, data from previously conducted studies, subsidence locations expected to require special design considerations, anticipated subsidence rates, and methods to mitigate the anticipated ground subsidence would be identified and incorporated into the design.

Land Acquisition

The approximate amount of additional lands to be acquired to accommodate the floodplain, levees, bypass channel, structures, and borrow was quantified based on parcel data in GIS shapefile format from Fresno and Madera counties. Since remaining portions of parcels that fall outside the Project area may not be as easily utilized by the land owners, the entire parcels were considered, where appropriate. The amount of land acquisition varies with alternative (approximately 2,450 to 3,300 acres).

Phased Implementation

The Project may utilize a phased approach to implementation of the selected alternative. Phased implementation would involve building selected components of the Project in separate construction phases, allowing Project funding to be secured over time. For example, the bypass channel and bifurcation structure could be built in a first phase, fish passage facilities in a second phase, and fish screens and levees and floodplain construction in a third phase. Exact phasing would be developed during the detailed design phase of the selected alternative.

2.2.5 Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

Alternative A (Compact Bypass with Narrow Floodplain and South Canal) includes:

- Building levees capable of conveying flows up to 4,500 cfs with 3 feet of freeboard.
- Restoring floodplain habitat an average of approximately 3,000 feet wide to provide benefit to salmonids and other native fishes.
- Constructing a channel and structures capable of conveying up to 4,500 cfs of Restoration Flows around the Mendota Pool.
- Constructing the South Canal and structures capable of conveying up to 2,500 cfs from Reach 2B to Mendota Pool.
- Providing upstream and downstream fish passage for adult salmonids and other native fishes, and downstream fish passage for juvenile salmonids, between Reach 2A and Reach 3.

This alternative would construct a channel between Reach 2B and Reach 3, the Compact Bypass channel, in order to bypass the Mendota Pool. Restoration Flows would enter Reach 2B, flow through the reach, then downstream to Reach 3 via the Compact Bypass channel. A canal to convey San Joaquin River water deliveries to Mendota Pool, the South Canal, would be built. The San Joaquin River control structure at the Chowchilla Bifurcation Structure would be removed, and a bifurcation structure would be built at the head of the South Canal to control flood diversions into the Chowchilla Bypass and water delivery diversions into Mendota Pool. Fish passage facilities and a fish screen would be built at the South Canal bifurcation structure to provide passage around the structure and prevent fish being entrained in the diversion. A fish barrier would be built in Reach 3 to direct up-migrating fish into the Compact Bypass channel. A new crossing would be built at the San Mateo Avenue crossing. These features are described in further detail in the sections below. See Figure 2-6 and Figure 2-7 for a plan view of the alternative's features.

Compact Bypass Channel

The bypass channel would convey 4,500 cfs around the Mendota Pool by constructing a channel just southwest of the existing Columbia Canal alignment. Once constructed, the bypass channel would become the new river channel. This alternative includes excavating the bypass channel, constructing levees and in-channel structures, removing existing levees, relocating or modifying existing infrastructure, and acquiring land. The in-channel structures may include bifurcation control structures, grade control structures, fish screen(s), fish passage facility(ies), fish barrier(s), Columbia Canal Siphon, as well as the Drive 10 ½ realignment and are discussed under Structures. The bypass channel and associated structures would provide downstream passage of juvenile Chinook salmon and upstream passage of adult Chinook salmon, as well as passage for other native fishes, while isolating Mendota Pool from Restoration Flows.

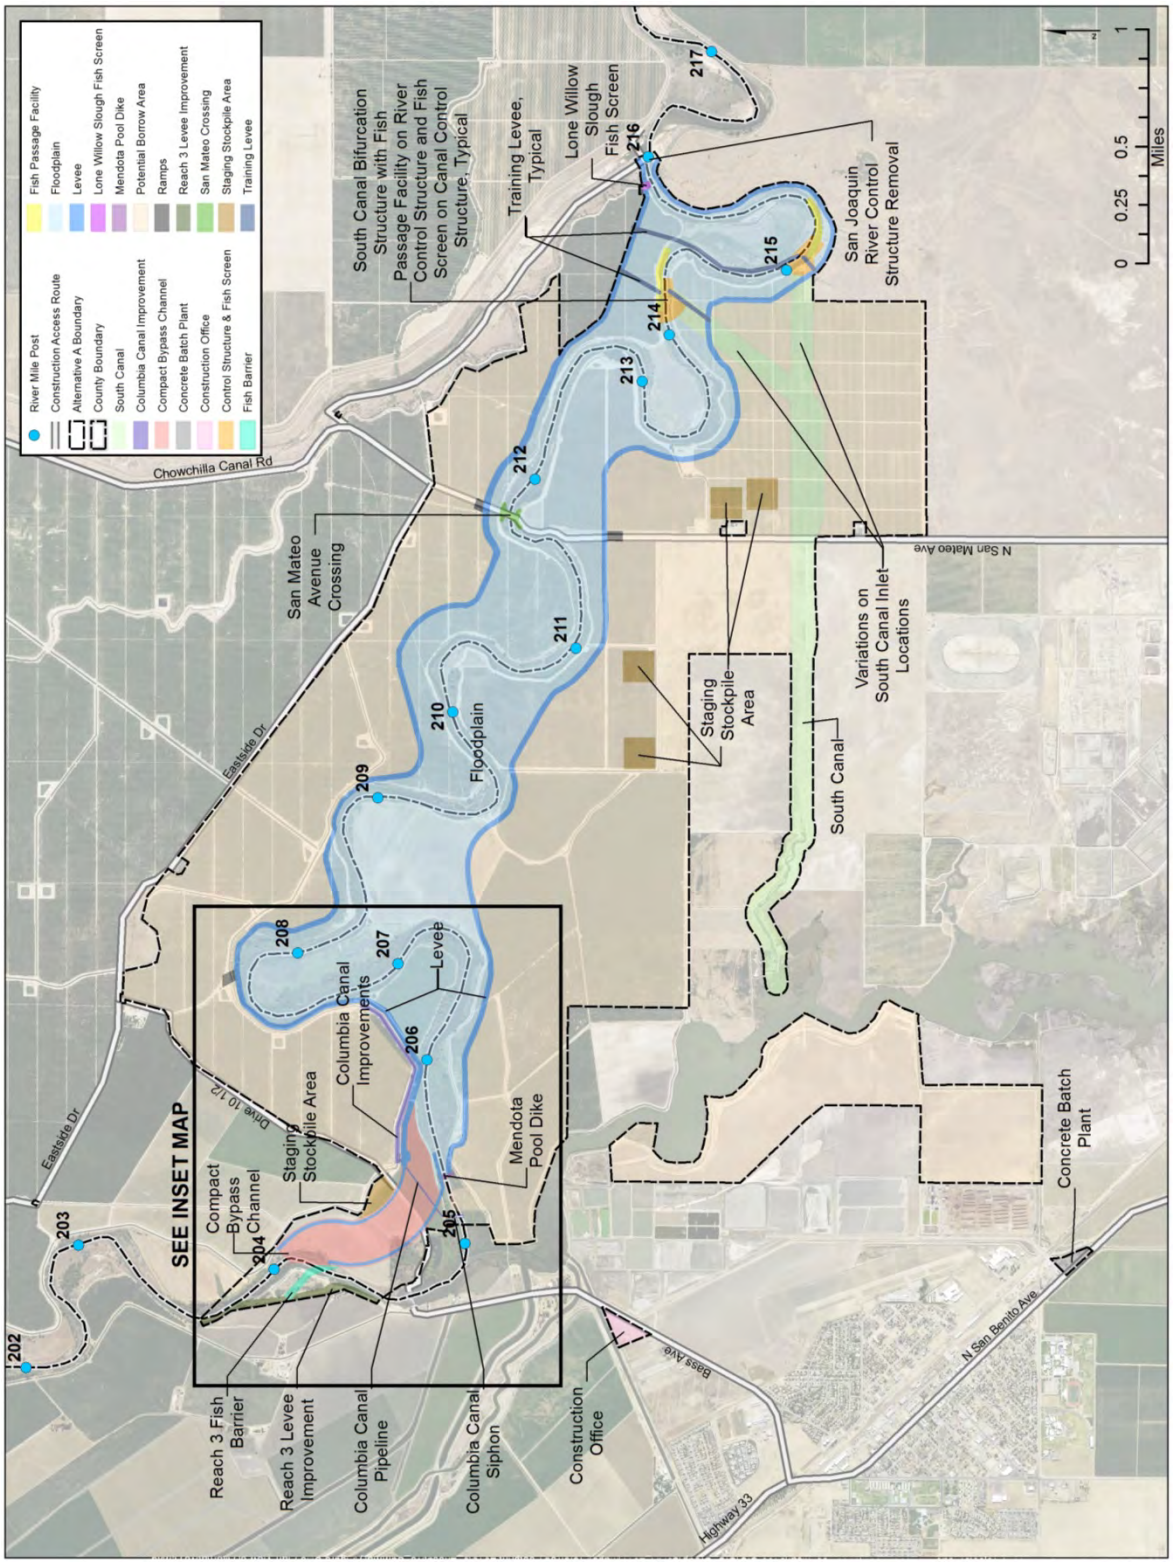

Figure 2-6.
Plan View of Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

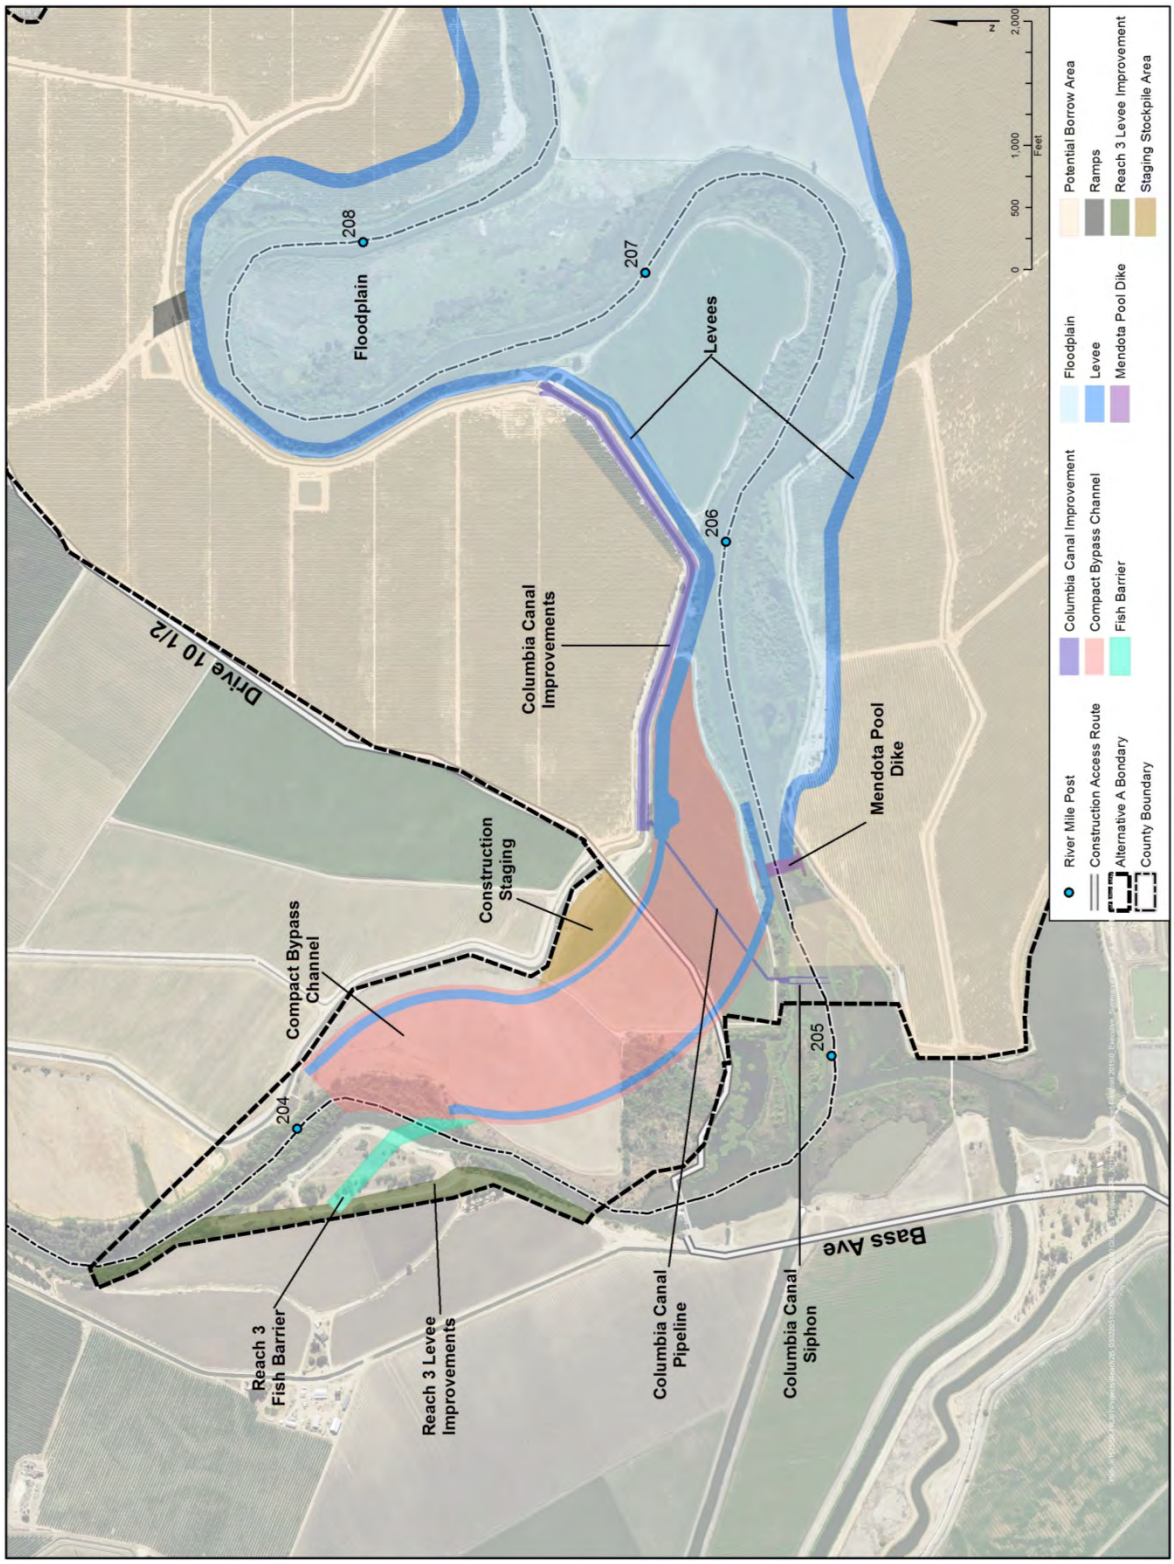

Figure 2-7.
Inset Map of Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

The bypass channel would connect to Reach 3 approximately 0.6 mile downstream from Mendota Dam (approximately RM 204), bypass the Mendota Pool to the north, and connect to Reach 2B approximately 0.9 mile upstream from Mendota Dam (approximately RM 205.5). The bypass channel would have a total length of approximately 0.9 mile. A siphon under the bypass channel would be constructed to connect the Columbia Canal to the Mendota Pool.

The bypass channel would be a multi-stage channel designed to facilitate fish passage at low flows, channel stability at moderate flows, and contain high flows. The low-flow channel would be designed for a capacity of around 200 cfs and would have a topwidth of approximately 110 feet and a depth of approximately 2 feet. The main channel would be designed for a capacity of around 1,860 cfs (approximately the 2-year annual peak Restoration Flow in Reach 2B) and would have an average topwidth of approximately 320 feet and total depth of approximately 6 feet. The floodplain bench would be designed with a shallow cross-slope (approximately 1 percent slope) to allow variable floodplain depths at flows between 1,860 cfs and 4,500 cfs. The channel design will be further refined during the final design process.

The channel, designed as an unlined earthen channel, would be approximately 5,300 feet long with a total corridor width of approximately 950 feet. The average slope of the channel between grade control structures would be approximately 0.0004 (approximately 2.1 feet/mile), while the total elevation drop would be approximately 12 feet including grade control structures. A series of grade-control structures would be included to achieve the necessary elevation change (see Grade Control Structures).

South Canal

The South Canal would deliver up to 2,500 cfs in water deliveries from the San Joaquin River to Mendota Pool. The South Canal could connect to the river at various locations, ideally on a straight section of the river or on the outside of bend. Two optional locations for the junction with the San Joaquin River are shown in Figure 2-6 at approximately RM 214.2 and RM 215. The South Canal would discharge into Fresno Slough via the Little San Joaquin Slough approximately 2.3 river miles south of Mendota Dam.

Water deliveries would be controlled at the upstream end of the South Canal by a bifurcation structure. The river control structure would have a fish passage facility for fish passage, and the canal control structure would have a fish screen to prevent entrainment. The control structures, fish screen, and fish passage facilities are discussed under Structures.

The South Canal could be concrete-lined or unlined. The unlined design would include maintained grasses in the channel. Either design would have a trapezoidal cross-section. The lined South Canal would have a top-width of approximately 90 feet, a total corridor width of approximately 180 feet (including levees and maintenance roads), and 2H to 1V side slopes on the canal banks and levees. The unlined South Canal would have a top-width of approximately 270 feet, total corridor width of approximately 490 feet (including levees and maintenance roads), and 3H to 1V side slopes on the canal banks and levees.

Levee heights would be based on a flow of 2,500 cfs and 3 feet of freeboard. Seepage control measures and erosion protection would be included as necessary to minimize seepage impacts and reduce erosion and scour in the canal. However, seepage is assumed to not be an issue for a lined canal, so seepage control measures would not be provided for the lined canal.

The South Canal would cross San Mateo Avenue, so a bridge crossing would be provided to maintain access. The bridge would include concrete deck, reinforcing steel, piles, and pile extensions, railing, excavation, and backfill.

Structures

The structures described below would be required to provide the operational flexibility to divert water to the Mendota Pool, provide fish passage, allow maintenance access to Mendota Dam, prevent fish entrainment and straying, and provide controlled elevation drop between Reach 2B and Reach 3.

San Joaquin River Control Structure at Chowchilla Bifurcation Structure Removal

The existing Chowchilla Bifurcation Structure consists of two control structures: one at the head of the Chowchilla Bypass and one across the San Joaquin River at RM 216. With the inclusion of a bifurcation structure at the head of the South Canal, a new control structure would be built across the San Joaquin River at the head of the canal. The new control structure would alleviate the need for the San Joaquin River control structure at the Chowchilla Bifurcation Structure because all diversions into the Chowchilla Bypass could be controlled from the new control structure at the head of the South Canal. As part of this alternative, the San Joaquin River control structure at the Chowchilla Bifurcation Structure would be demolished.

South Canal Bifurcation Structure

A bifurcation structure would be constructed at the upstream end of the South Canal. The bifurcation structure consists of two control structures: one across the path of Restoration Flows (San Joaquin River) and one across the path of water deliveries to Mendota Pool (South Canal).

The control structure across the path of the Restoration Flows would be designed to accommodate up to 4,500 cfs and consists of six 20-foot-wide bays for a structure length of approximately 140 feet. Conditions in this control structure would be designed based on NMFS 2001 and NMFS 2008 fish passage criteria. The control structure across the path of the water deliveries would be designed to accommodate up to 2,500 cfs and consists of four 20-foot-wide bays for a structure length of approximately 100 feet. Flow through each bay would be controlled by a gate (e.g., radial (Tainter) or inflatable Obermeyer). In the final design, the number and size of the gates may be modified. The size of the gates would be determined by the design maximum flow.

The Restoration Flow path structure includes a fish passage facility on the side of the structure, and the water deliveries flow path structure includes a fish screen upstream of the structure. Each control structure would be placed in the middle of the channel and has earthen embankments connecting the structure to the proposed levees. The connector

embankments would be similar in height to the surrounding San Joaquin River levees. The connector embankments may include culverts, gates, weirs, inflatable bladder dams, or other features to improve flow and fish passage on the floodplain when water deliveries are not occurring. A 16-foot-wide roadway and 20-foot-wide maintenance/operations platform would be provided over each control structure.

The bifurcation structure would be used to control flow to the river, to the canal providing water deliveries to Mendota Pool (South Canal), and to the Chowchilla Bypass. Flow would be backwatered in the upper portion of Reach 2B above the canal bifurcation structure to operate the Chowchilla Bypass. Therefore, San Joaquin River levee heights would be increased over that segment of Reach 2B, particularly near the canal bifurcation structure.

South Canal Fish Passage Facility

The South Canal bifurcation structure would include a fish passage facility on the side of the control structure across the Restoration Flow path. The fish passage facility would be necessary to provide passage during water deliveries and for Restoration Flows where passage conditions through the control structure may not be ideal.

Passage Facility Design

The design of the fish passage facility would be based on criteria in *Anadromous Salmonid Passage Facility Design* (NMFS 2008). The size and geometry of the fish passage facility would be dictated by the flow requirements for juvenile and adult fish in Table 2-1. Several types of fish passage facility may be considered in detailed design: vertical slot weir ladder design was included for its ability to accommodate a greater range of water depths (hydraulic head at the upstream and downstream ends), but the design may also consider ice-harbor, pool and chute, rock ramp fishway or other passage facility designs.

A roadway would need to be built over the fish passage facility to connect the maintenance road atop the river control structure with the levee road on the south side of the river. The roadway would be supported by the vertical concrete walls of the fish passage facility or other structural features.

Attraction Flows

The attraction flow magnitude will be 5 to 10 percent of the total flow through the control structure over the path of Restoration Flows. The Project requires conveyance of at least 4,500 cfs, so the attraction flow at the passage facility entrance could be as high as 450 cfs. The passage facility itself may have a design flow rate less than the maximum attraction flow. In this case, the balance of attraction flows could be provided at the passage facility entrance (downstream side) through supplementary water, described below.

Supplementary Water

Supplementary water, if incorporated into the facility, is water already in the river and which is piped to the fish passage facility entrance to augment attraction flows. No additional water supply beyond what would be flowing in the river is required. The

supplementary water allows the passage facility to operate under a wider range of river flows by supplying additional attraction flow when the need exceeds the design flow rate through the passage facility. Supplementary water would also be used to control the hydraulic head at the passage facility entrance.

Supplementary flow would be collected by a water delivery intake structure located upstream from the fish passage facility (see Figure 2-8). The intake structure would include an automated cleaning system, trash rack and a fish screen to prevent migrating fish from entering the intake. River water would enter the intake structure, and travel downriver through pipes to the passage facility entrance.

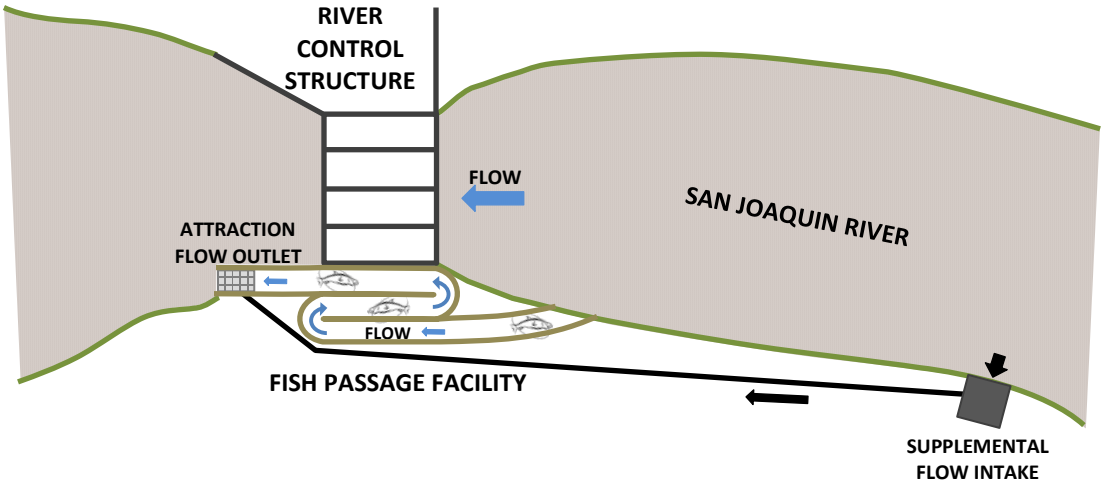

Figure 2-8.
Supplementary flow system plan-view diagram

South Canal Fish Screen

A fish screen would be included at the head of the South Canal where water deliveries would be diverted from the river toward Mendota Pool. The fish screen would be necessary to keep or return out-migrating juvenile salmon to the San Joaquin River (the path of Restoration Flows) during water deliveries.

The screen would be designed to pass flow up to 2,500 cfs. The type of fish screen could be a fixed flat plate in "V" configuration, vertical flat plate, inclined flat plate, cone, or cylindrical screens. Depending on the design type, the fish screen facility may include trash racks, stainless steel wedge wire fish screens, flow control baffle systems behind the screens, screen cleaning systems for the trash racks and screens, bypass flow control weirs, fish-friendly pumps, and/or fish bypass pressure pipelines. The trash racks would be installed at the entrance to the screen structures to protect screens from trash, logs, and other large debris.

Approach, sweeping, and bypass entrance velocities would be kept within established fish screen criteria (NMFS 2008). Flow through the fish screens may be controlled by baffles behind the fish screens. Cleaning of the screens would be accomplished using an

automated brush system. Electric power would be needed for fish friendly pumps, if included, and screen cleaning systems. Operation of the fish screens would include methods to reduce predation of juvenile fish (e.g., noise systems to scatter predators, netting, and periodic draining of the screen return pipes).

San Mateo Avenue Crossing Replacement

The San Mateo Avenue crossing is an existing river crossing located within a public right-of-way in Madera County and on private land in Fresno County at approximately RM 211.8. The crossing transitions from public right-of-way to private land at the center of the river. In order to maintain vehicular access, accommodate increased flow magnitudes associated with Restoration Flows, and provide fish passage, an improved crossing would be included with this alternative. The crossing would accommodate the increased flows in the river by maintaining the required velocities for proper fish passage for flows up to 4,500 cfs. The crossing would be designed to meet NMFS 2001 and NMFS 2008 passage criteria. When flow is within the capacity of the culverts (e.g., less than 1,500 cfs), fish passage would occur in the culvert. The crossing would be overtopped during higher flows.

The proposed San Mateo Avenue crossing includes installing a low flow or dip crossing with multiple, counter-sunk concrete box culverts designed for highway loading. The structure includes armoring along the entrance and exit of the structure as well as along the channel banks in the immediate vicinity of the structure. The armoring would be necessary to protect the structure during overtopping flows. Culverts would be embedded below the existing channel bed. Grouted riprap would be placed in the culvert below the existing channel bed to prevent channel scour reaching the floor of the culvert and to create a roughened boundary layer for fish passage. Native bed material would be placed above the grouted riprap up to the existing channel bed elevation to provide passage conditions similar to that which exists in the adjacent natural stream.

Mendota Pool Dike

Adjacent to the head of the Compact Bypass, a dike across the existing river channel would be needed to prevent water in Mendota Pool from flowing into the Compact Bypass. The dike would be of similar design as the levees in Section 2.2.4 including seepage control measures to prevent seepage from the Pool into the Compact Bypass. The dike would run from the proposed Reach 2B levee on the south side of the river, across the river, to proposed left-bank levee of the Compact Bypass. This structure would likely be regulated by DWR Division of Safety of Dams (DSOD).

Drive 10 ½

The Compact Bypass would cross existing Drive 10 ½, which provides access to the east side of Mendota Dam. With this alternative, the road would end at east side of the bypass channel and would not continue to Mendota Dam.

Reach 3 Fish Barrier

A fish exclusion barrier would be included in Reach 3 near the downstream end of the Compact Bypass to prevent adult fish from migrating beyond the bypass channel up to the base of Mendota Dam, which during most flows out of Mendota Pool, would be a

dead end for fish passage. This would lead to delays in adult salmon migration or potentially death. Although out-migrating fish would not be expected to be present downstream from Mendota Dam, the fish barrier would allow juveniles to pass the structure.

The exclusion barrier design would be a high-flow picket barrier, which is a flow-through structure of closely spaced bars (i.e., pickets) that prevent adult fish from traveling upstream in the river to Mendota Dam at flows up to a combined discharge of 4,500 cfs (Mendota Dam and the Compact Bypass). The design accounts for a range of flow options from routing the entire 4,500-cfs flow through the structure (flood flows from the James Bypass), to routing a 600-cfs irrigation delivery through the structure with up to 3,900 cfs being routed down the Compact Bypass, to routing no flow through the structure with up to 4,500 cfs down the Compact Bypass.

The total length of the structure would be approximately 1,410 feet, with 260 feet across the main channel and 1,150 feet across the overbanks. The base of the structure would consist of a concrete sill connected to concrete piles, which extend into clay layers. The structure would be approximately 20 feet high in the main channel and 9 feet high in the overbanks. Riprap would be placed 2 feet thick at the entrance and exit of the sill to prevent erosion. The fish barrier meets the average through-velocity criteria of 1.0 foot per second (fps) in *Anadromous Salmonid Passage Facility Design* (NMFS 2008).

In order to meet velocity criteria for the structure, some floodplain grading between the existing Reach 3 levees would be required to provide even flow-through conditions. In addition, approximately 4,200 linear feet of improvements to the Reach 3 left-bank levee are included to ensure that backwater conditions at the structure do not affect adjacent property. The improved Reach 3 levee would have the same alignment as the existing levee.

Grade Control Structures

A series of several (10 to 18), approximately 0.5-foot-high grade-control structures would be included within the bypass channel to achieve the necessary elevation change between Reach 2B and Reach 3. The grade control could be provided by structures such as sheet pile weirs or constructed rock riffles.

Rock riffles have benefits for native fish migration, but they present construction challenges in the sandy substrate of the Reach 2B and Reach 3 area. The flow over constructed rock riffles may reduce the disorienting effects on juveniles from rapidly changing hydraulics otherwise created at weir structures, and they are more favorable to sturgeon, which do not jump. Constructed rock riffles may be less favorable to predators which can hold in the quiescent pools below weir structures. However, placing rock in sandy substrate requires engineered foundation materials (layers of rock in gradually decreasing sizes) to prevent undermining the structure. Further analysis during design will determine which type of grade control structure will be selected.

Sheet pile weirs would be constructed with capped and anchored sheet piles. Caps on the sheet piles would be used to avoid injuring fish and can be surfaced with natural

materials (i.e., grouted rock) to emulate natural conditions which fish may be exposed to in non-manmade portions of the San Joaquin River.

Each grade control structure would extend across the main channel and key into the overbanks to protect against flanking, resulting in a total structure width of about 420 feet.

Vegetated revetment would be included along both channel banks within the portion of the bypass containing the grade control structures to provide additional protection against flanking. It is assumed that the revetment would consist of buried riprap covered with topsoil, erosion control fabric, and native woody vegetation, so that fish would experience natural channel banks. Native woody vegetation directly upstream, downstream, and adjacent to the grade control structures would provide shading and opportunities for juveniles to hide from predators.

Fish Habitat and Passage

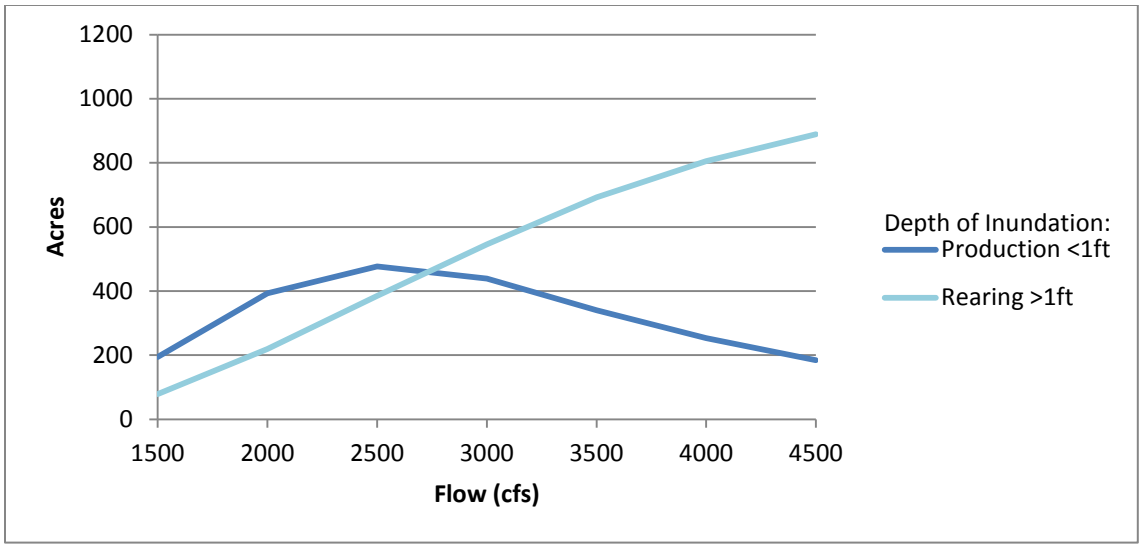
The purpose of the floodplain would be to provide riparian and floodplain habitat and support the migration and seasonal rearing of salmonids and other native fishes in Reach 2B. The floodplain has an average width of approximately 3,000 feet and an inundated area of approximately 850 acres at 2,500 cfs.

This alternative provides floodplain habitat resulting in approximately 450 acres of shallow water habitat for primary production[3] as well as approximately 400 acres of habitat that supports direct rearing[4] at 2,500 cfs. Approximately 55 percent of the floodplain in this alternative would inundate less than 1 foot deep at 2,500 cfs. This alternative also retains approximately 200 acres of shallow water habitat at flows up to 4,500 cfs.

Figure 2-9 below presents conceptual inundation areas for primary production and rearing habitats as they vary by flow. Inundation acreages may change during the design process.

[3] Primary production is defined as the production of organic compounds from atmospheric or aquatic carbon dioxide, principally through the process of photosynthesis. The organisms responsible for primary production are known as primary producers or autotrophs, and form the base of the food chain (e.g., algae). Primary production also includes aquatic invertebrate species that feed on algae and are a food source for fish.

[4] Rearing habitat is defined as those areas with characteristics that support growth and maturation of juvenile salmonids prior to their outmigration as smolts. For the purpose of analysis, juvenile salmon direct rearing habitat is the area with water greater than 1.0 feet deep at 2,300 cfs, a flow which will occur in approximately one out of every 2 years for a sustained period of at least 20 days in the period March 15 to May 15 (see further discussion in the Project Description TM Attachment A – Alternatives Evaluation, Section 6.2.2 (SJRRP 2012). The modeled flow of 2,500 cfs is used as a surrogate for 2,300 cfs.



Source: Tetra Tech 2012

Figure 2-9.
Potential Inundation Acreage by Flow for Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

In the Compact Bypass channel, floodplain benches with an approximate average width of 300 feet on each side the main flow portion of the bypass channel are included (see section "Compact Bypass Channel.") Riparian and floodplain habitat would develop on the benches in the bypass channel to benefit migrating fish and promote a stable channel and sediment transport from Reach 2B to Reach 3.

This alternative includes several facilities that fish may encounter or need to pass to migrate between Reach 3 and Reach 2B (from downstream to upstream):

- A fish barrier near the downstream end of the Compact Bypass.
- Several (10 to 18) in-channel grade control structures in the Compact Bypass.
- The San Mateo Avenue crossing.
- Four fish screen return outlets from the South Canal fish screen.
- A bifurcation control structure at the South Canal with fish passage facility.
- A fish screen near the upstream end of the South Canal.
- Fish screens at Lone Willow Slough, Big and Little Bertha pumps, and other smaller diversions (these screens are discussed in Section 2.2.4).

Each structure would be designed to perform according to the fish passage design criteria (see Section 2.2.4). In addition, the channel and floodplain incorporate riparian plantings to provide cover, woody material, and velocity variability, while the design footprint allows sufficient space to incorporate channel structure variability during detailed design, all of which may help to reduce stress and predation.

This alternative includes a fish barrier at the downstream end of the bypass channel to keep fish from migrating into false migration pathways. Without the barrier, a false migration pathway up to the base of Mendota Dam would be available to fish in all years, and a false migration pathway into Mendota Pool and Fresno Slough (potentially into the King River system) would occur in about one in five years, when the boards are taken out of Mendota Dam to pass Pine Flat flood releases into Reach 3. However, with the barrier, which would be designed to accommodate flows up to 4,500 cfs, fish would not be able to migrate to Mendota Dam or enter Mendota Pool, but they would be guided into the bypass channel and Reach 2B.

Floodplain and Riparian Habitat

This alternative includes passive riparian habitat restoration and compatible agricultural activities in the floodplain. It is assumed that over time wetland communities (obligate, facultative-wet, and facultative species) would develop within the main channel and that a dense riparian scrubland would develop along the main river channel banks. Between the main river channel banks and the proposed levees, agricultural practices (e.g., annual crops, pasture, or floodplain-compatible permanent crops) could occur.[5] The Restoration Flows would be used to recruit new vegetation along the channel. This alternative relies upon existing seed banks (upstream of the Project and on portions of existing Reach 2B levees to remain) and Restoration Flows for vegetation recruitment, and no supplemental water supply is required. Invasive, non-native species would be removed from the channel and riparian areas during or following construction, and the Project would include long-term management for invasive plants.

Several native vegetation alliances may develop in the riparian areas, such as saltgrass flats, sandbar willow thickets, California mugwort brush, black willow thickets, riparian bank herbs, California bulrush marsh, buttonwillow thickets, Oregon ash groves, creeping rye grasslands, and Fremont cottonwood forests.

Existing Native Vegetation Protection

The existing native vegetation in the Project area designated to remain would be temporarily fenced with orange snow fencing (or equivalent) to prevent entry, driving, parking, or storing equipment or material within these areas during construction. Existing vegetation would be left in place or only minimally trimmed to facilitate access and work at the site. The existing soil is an ideal growing medium for all the desired native plants. In order to maximize plant growth and planting success, existing soil and topsoil would be preserved unless the soil contains invasive non-native seed or fragmented stems and rhizomes, in which case it should not be preserved. Disturbance during construction would be minimized to the maximum practicable extent.

Invasive Species Control

Invasive, non-native species would be removed from the Project area during the construction phase. Invasive species management would consist of removal of the most invasive non-native species within the reach such as giant reed grass (*Arundo donax*),

[5] Rearing on floodplains with agricultural practices has been shown to be compatible with salmon rearing, and provide faster salmon growth rates compared to in-channel rearing alone (Sommer et al. 2001).

perennial pepperweed (*Lepidium latifolium*) and poison hemlock (*Conium maculatum*). Invasive species management would also include removal of other invasive species that are currently found in upstream reaches and may eventually colonize in the Project area such as red sesbania (*Sesbania punicea*), salt cedar (*Tamarix* species), and Chinese tallow (*Sapium sebiferum*). Invasive plant removal techniques may include mechanical removal, root excavation, hand pulling, mowing, disking, controlled burning, grazing, aquatic-safe herbicides, or a combination of techniques as appropriate.

Long-Term Management

While it is not anticipated that major management actions would be needed, the key objective of long-term management would be to monitor and identify any environmental issues that arise, and use adaptive management to determine what actions would be most appropriate to correct these issues.

The general management approach to the long-term maintenance of the floodplain areas would be to maintain quality habitat for each natural resource, on-going monitoring and maintenance of key environmental characteristics of the entire floodplain area within the reach. An adaptive management approach would be used to incorporate changes to management practices, including corrective actions as determined to be appropriate by Reclamation and/or CSLC. Adaptive management includes those activities necessary to address the effects of climate change, fire, flood, or other natural events, force majeure, etc.

The expected long-term management needs and activities necessary to maintain any on-site mitigation sites would be resource specific long-term maintenance activities and other general maintenance activities such as exotic species elimination, grazing management, clean-up and trash removal, infrastructure management such as gate, fence, road, culvert, signage and drainage-feature repair, and other maintenance activities necessary to maintain the riparian and floodplain habitat quality.

Water Deliveries

This alternative includes the South Canal for making up to 2,500 cfs in water deliveries from the San Joaquin River to Mendota Pool. Water deliveries to the Pool would include diversion of Friant Dam releases that are meant to satisfy the Exchange Contract as well as diversion of San Joaquin River flood flows if there is demand in Mendota Pool.

When water deliveries occur, the gates at the South Canal bifurcation structure would be manipulated to control flows into the downstream river channel and allow flows into the South Canal. To create sufficient hydraulic head to allow water to flow into the canal, operation of the gates would include backwatering a small portion of the San Joaquin River upstream of the South Canal bifurcation structure. The extent of the backwater is anticipated to be small and dependent on the design slope of the canal. Up-migrating fish passage along Reach 2B would occur through the South Canal fish passage facility during water deliveries. The South Canal fish screen would capture out-migrating fish entering the diversion and return them to the river. Some flow in the downstream river channel would be maintained during water delivery operations during fish migration periods.

Construction Considerations

The total construction timeline for this alternative is estimated to range approximately from 102 to 132 months (8.5 to 11 years); opportunities to shorten the overall schedule through construction efficiencies will be studied during the detailed design process.

Soil improvements for possible liquefiable soils may be required to protect proposed structures from damage or failure during an earthquake. All proposed structures would be designed to account for potential liquefaction. Soil improvements could include removing and replacing soils with adequate materials, injecting soil-cement slurry, vibrofloatation, dynamic compaction, structural foundation piles (stone or reinforced concrete), and other techniques.[6]

Flow in the San Joaquin River, operations at the existing Mendota Dam, and operation of the existing Columbia Canal must be maintained during construction. The majority of the Compact Bypass channel would likely be constructed without interruption to the San Joaquin River flow or the Columbia Canal.

The construction of the control structure across the existing river channel would require removable cofferdams in three phases to facilitate the construction without blocking the flow. If flow is present in the river during the construction period, flow would be diverted around the work area via a temporary diversion pipe or canal and fish passage would be provided. Cofferdams include two rows of braced sheet piling filled with dirt for stability and seepage control. The total height of the cofferdam is assumed to be 24 feet of which 12 feet would be above the channel bed. The control structures to be constructed on dry land (e.g., head of the South Canal) would not require cofferdams.

Stone slope protection (riprap) would be provided on the upstream and downstream slopes of the control structure embankment including some portions of the side slopes of the channel itself to prevent scouring. Riprap would be placed on bedding over geotextile fabric.

Construction of the fish screen and return/bypass fish pipes would take place in the dry using conventional construction methods and must be coordinated with construction of the water delivery canal. The exception to this is the outlet for the fish return pipes, which would require a cofferdam. All fish facility structures and pipes with surfaces exposed to fish require additional attention to surface-smoothness.

For construction of the control structures and fish passage facilities, it would be desirable to maintain a minimum flow during construction; the amount or range of flows during construction has not yet been identified. A sheet pile cofferdam would be provided for the river control structure and/or the canal control structure and the water diverted away from the construction. Additional sheet piling would be provided to divert flows through the new bifurcation structure while the fish passage facility is constructed.

[6] Vibrofloatation uses a vibrating probe that penetrates the soil and causes the grain structure to collapse and increase the density of the soil. Dynamic compaction involves dropping a heavy weight onto soil to compact it.

Cofferdams would likely be required around portions of the construction site at the San Mateo Avenue crossing. Since a portion of the existing crossing is private (not a public road), it was assumed that access could be closed during construction. Construction would be timed so that the lesser Restoration Flows (5 to 195 cfs) can be routed around the structure during construction. At high flows water would flow over the structure, in addition to through the proposed culverts. To protect the structure during high flows, the proposed fill would be enclosed in concrete and cutoff walls and riprap would be included to prevent damage to the structure during over topping flows.

Summary

Table 2-2 summarizes the levees, relocations, land acquisition, and construction schedule associated with Alternative A (Compact Bypass with Narrow Floodplain and South Canal) based on design, field, and evaluation criteria data prepared for the EIS/R.

Table 2-2.
Alternative A (Compact Bypass with Narrow Floodplain and South Canal)
Levees, Relocations, and Land Acquisition

	Left Levee	Right Levee
Levee Length	8.7 miles	7.1 miles
Average Levee Height	5.8 feet	5.4 feet
Fill Volume	345,200 cubic yards	269,700 cubic yards

Relocations			
Electrical Distribution	43,500 feet	Barn/Shed	1
Gas Transmission	10,000 feet	Facility	1
Water Pipeline	31,000 feet	Groundwater Well	26
Canal	32,500 feet	Lift Pump	10
Culvert	1	Power Pole	144
Diversion	3	Dwelling	2

Land Acquisition and Construction Schedule	
Land Acquisition[1]	2,700 acres
Time to Build[2]	132 months

[1] Total acreage includes areas that are sovereign and public trust lands.

[2] Construction timeline does not include the time that would also be needed to complete the NEPA/CEQA documentation process, obtain permits, appraise and acquire land, and perform pre-construction surveys.

2.2.6 Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure) includes:

- Building levees capable of conveying flows up to 4,500 cfs with 3 feet of freeboard.
- Restoring floodplain habitat an average of approximately 4,200 feet wide to provide benefit to salmonids and other native fishes.

- Constructing a channel and structures capable of conveying up to 4,500 cfs of Restoration Flows around the Mendota Pool.
- Constructing structures capable of conveying up to 2,500 cfs from Reach 2B to Mendota Pool.
- Providing upstream and downstream fish passage for adult salmonids and other native fishes, and downstream fish passage for juvenile salmonids, between Reach 2A and Reach 3.

This alternative would construct a channel between Reach 2B and Reach 3, the Compact Bypass channel, in order to bypass the Mendota Pool. Restoration Flows would enter Reach 2B at the Chowchilla Bifurcation Structure, flow through Reach 2B, then downstream to Reach 3 via the Compact Bypass channel. The existing Chowchilla Bifurcation Structure would continue to divert San Joaquin River flows into the Chowchilla Bypass during flood operations, and a fish passage facility and control structure modifications would be included at the San Joaquin River control structure at the Chowchilla Bifurcation Structure. A bifurcation structure would be built at the head of the Compact Bypass channel to control diversions into Mendota Pool. Fish passage facilities would be built at the Compact Bypass bifurcation structure to provide passage around the structure. The existing crossing at the San Mateo Avenue would be removed. These features are described in further detail in the sections below. See Figure 2-10 and Figure 2-11 for a plan view of the alternative's features. Elements that are common to all alternatives (described in Section 2.2.3) would be implemented under Alternative B.

Compact Bypass Channel

The bypass channel would convey 4,500 cfs around the Mendota Pool by constructing a channel just southwest of the existing Columbia Canal alignment. Once constructed, the bypass channel would become the new river channel. This alternative includes excavating the bypass channel, constructing levees and in-channel structures, removing existing levees, relocating or modifying existing infrastructure, and acquiring land. The in-channel structures include the bifurcation control structure, grade control structures, fish screen, fish passage facility, Columbia Canal Siphon, as well as the Drive 10 ½ realignment and are discussed under Structures. The bypass channel and associated structures provide downstream passage of juvenile Chinook salmon and upstream passage of adult Chinook salmon, as well as passage for other native fishes, while isolating Mendota Pool from Restoration Flows.

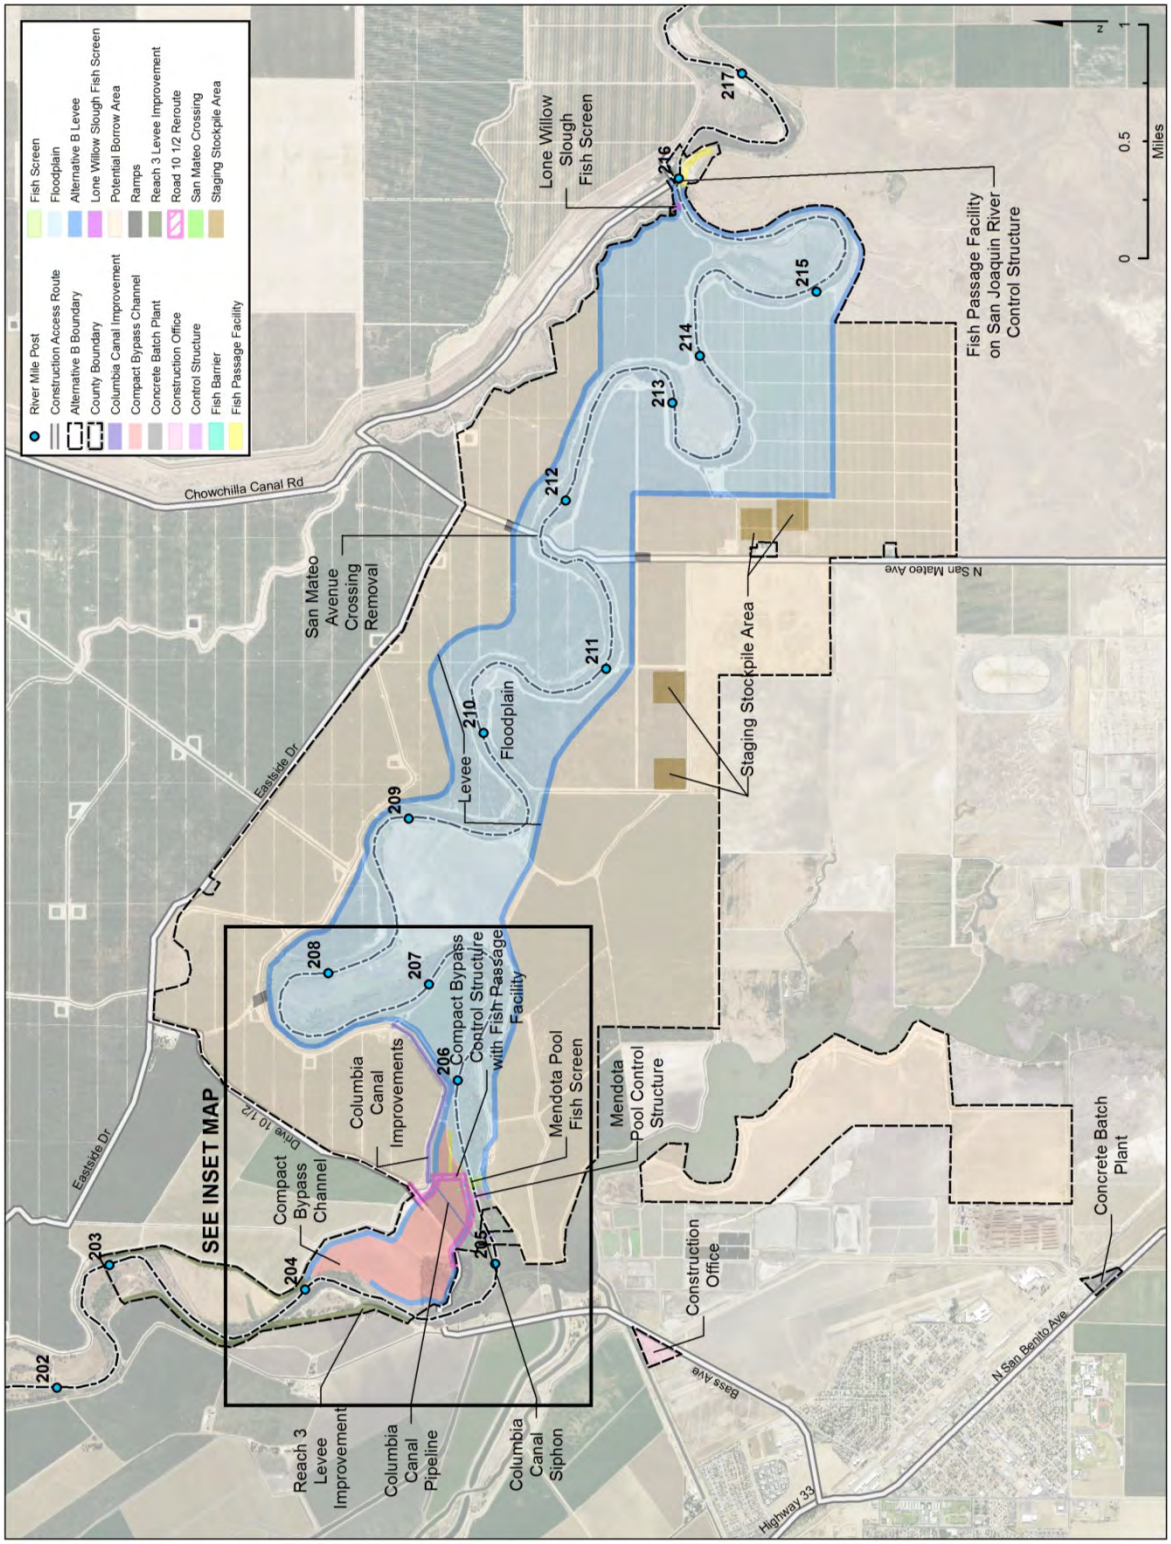


Figure 2-10.
Plan View of Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure)

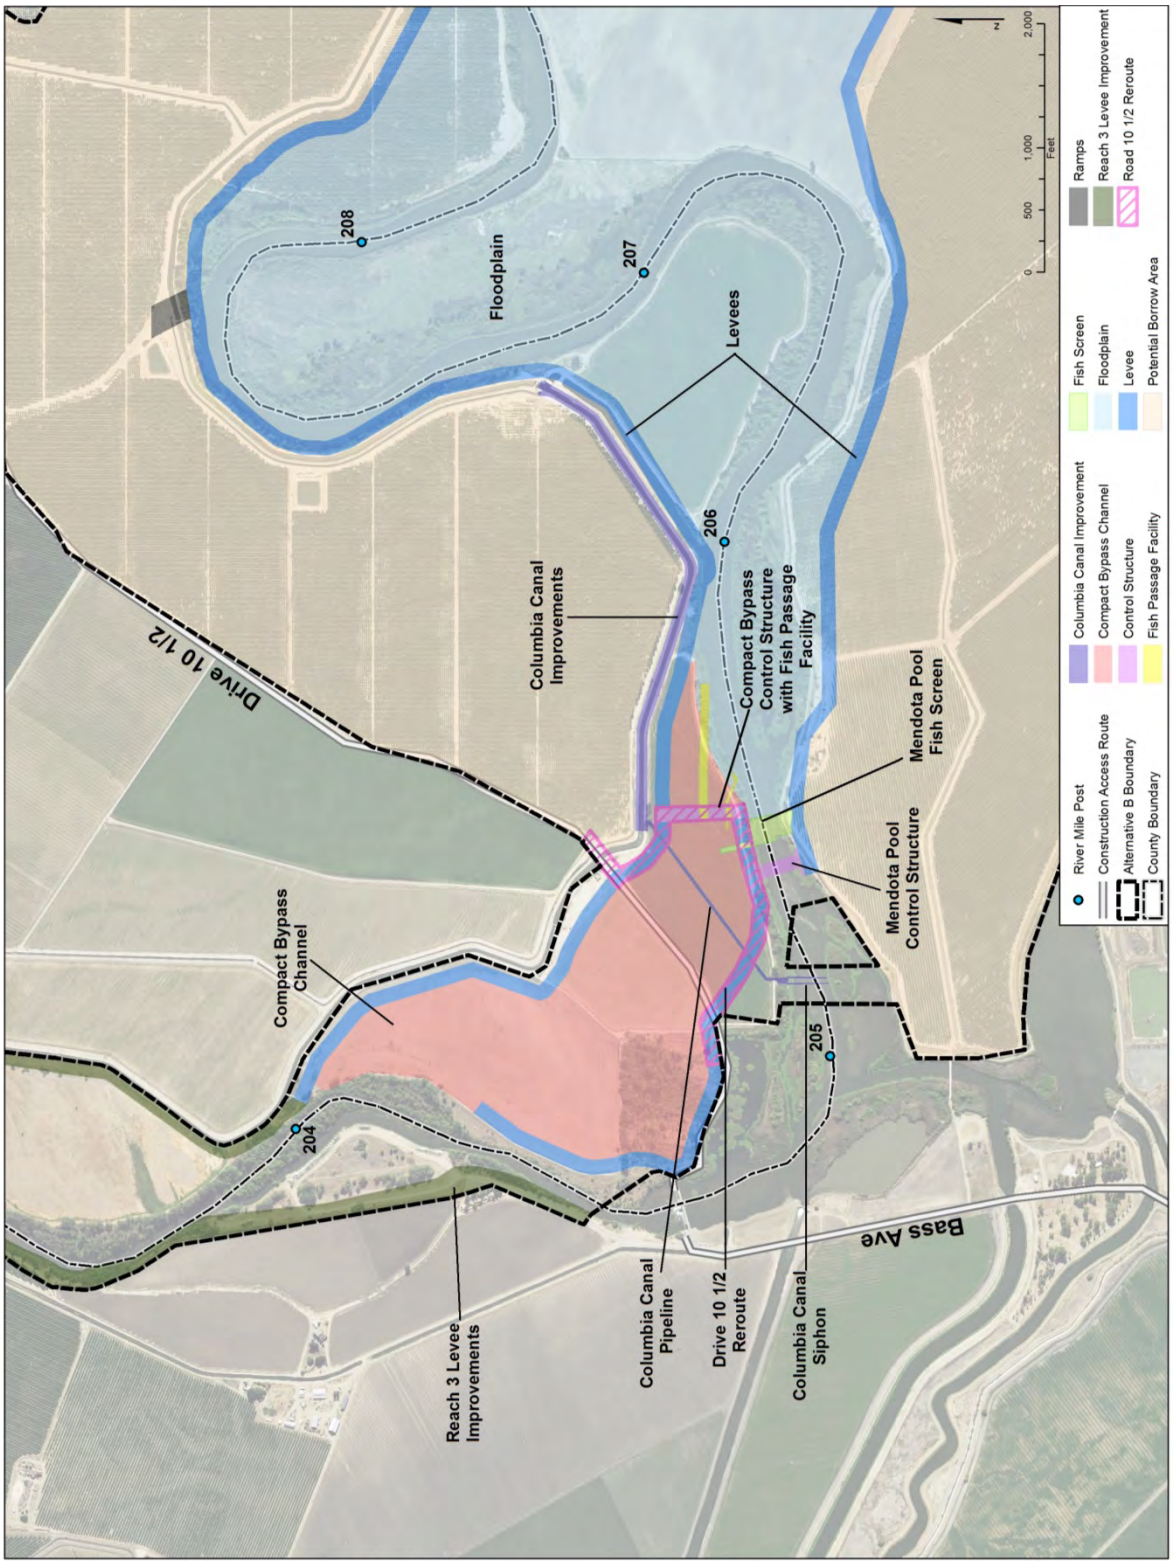

Figure 2-11.
Inset Map of Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure)

The bypass channel would connect to Reach 3 approximately 0.6 mile downstream from Mendota Dam (approximately RM 204), bypass the Mendota Pool to the north, and connect to Reach 2B approximately 0.9 mile upstream from Mendota Dam (approximately RM 205.5). The bypass channel would have a total length of approximately 0.9 mile. A siphon under the bypass channel would be constructed to connect the Columbia Canal to the Mendota Pool.

The bypass channel would be a multi-stage channel designed to facilitate fish passage at low flows, channel stability at moderate flows, and contain high flows. The low-flow channel would be designed for a capacity of around 75 cfs and would have a topwidth of approximately 50 feet and a depth of approximately 1 to 2 feet. The base flow channel would be designed for a capacity of around 200 cfs and would have a topwidth of approximately 70 feet and a depth of approximately 3 feet. The main channel would be designed for a capacity of around 1,500 cfs and would have an average topwidth of approximately 190 feet and total depth of approximately 5 feet. The floodplain bench would be approximately 150 feet wide on average on both sides of the main channel and designed with a shallow cross-slope (approximately 1 percent slope) to allow variable floodplain depths at flows between 1,500 cfs and 4,500 cfs.

The channel, designed as an unlined earthen channel, would be approximately 5,300 feet long with an average total corridor width of approximately 1,150 feet. The total elevation drop would be approximately 3 to 7 feet including grade control structures. A series of grade-control structures would be included to achieve the necessary elevation change (see Grade Control Structures). Channel complexity will be incorporated as appropriate per the Rearing Habitat Design Objectives.

Structures

The structures described below would be required to provide the operational flexibility to divert water to the Mendota Pool, provide fish passage, allow maintenance access to Mendota Dam, prevent fish entrainment and straying, and provide controlled elevation drop between Reach 2B and Reach 3.

Fish Passage Facility on the San Joaquin River Control Structure at the Chowchilla Bifurcation Structure

The existing San Joaquin River control structure at the Chowchilla Bifurcation Structure would not be passable by up-migrating salmon and native fish for all flows and flow splits between the river and the Chowchilla Bypass. The undershot gates, sill across the downstream side of the structure, and trash rack on the upstream side contribute to upstream passage difficulties at high, low, and all flows, respectively. A fish passage facility would be required for upmigrating salmon and other native fish to swim into Reach 2A from Reach 2B under most conditions.

Passage Facility Design

The design of the fish passage facility would be based on criteria in *Anadromous Salmonid Passage Facility Design* (NMFS 2008). The size and geometry of the fish passage facility would be dictated by the flow requirements for juvenile and adult fish (see Table 2-1). Several types of fish passage facility may be considered in detailed

design: vertical slot weir ladder design was included for its ability to accommodate a greater range of water depths (hydraulic head at the upstream and downstream ends), but the design may also consider ice-harbor, pool and chute, rock ramp fishway or other passage facility designs.

Attraction Flows

The attraction flow magnitude will be 5 to 10 percent of the total flow through the control structure over the path of Restoration Flows. The Project requires conveyance of at least 4,500 cfs, so the attraction flow at the passage facility entrance could be as high as 450 cfs. The passage facility itself may have a design flow rate less than the maximum attraction flow. In this case, the balance of attraction flows could be provided at the passage facility entrance (downstream side) through supplementary water, described below.

Supplementary Water

Supplementary water, if incorporated into the facility, is water already in the river and which is piped to the fish passage facility entrance to augment attraction flows (see Figure 2-8). No additional water supply beyond what would be flowing in the river is required. The supplementary water allows the passage facility to operate under a wider range of river flows by supplying additional attraction flow when the need exceeds the design flow rate through the passage facility. Supplementary water would also be used to control the hydraulic head at the passage facility entrance. Supplementary flow would be collected by a water delivery intake structure located upstream from the fish passage facility. The intake structure would include an automated cleaning system, trash rack and a fish screen to prevent migrating fish from entering the intake. River water would enter the intake structure, and travel downriver through pipes to the passage facility entrance.

San Joaquin River Control Structure at the Chowchilla Bifurcation Structure Modifications

In addition to the passage facility, the San Joaquin River control structure at the Chowchilla Bifurcation Structure would be modified to improve fish passage through the control structure itself or to improve operations of the passage facility. Fish passage through the modified river control structure may meet passage criteria only for certain flows, so the fish passage facility described above would still be required.

Improvements to the river control structure could include removing the trash racks, replacing one or more radial gates with over-shot gates (e.g., inflatable Obermeyer weir gates), notching or removal of the baffle wall or weir, removing the dragon's teeth, and replacing or modifying the scour protection. Improvements would be designed based on NMFS 2001 and NMFS 2008 passage criteria. Improvements would not affect the ability of the structure to divert flood water into the Chowchilla Bypass.

San Mateo Avenue Crossing Removal

The San Mateo Avenue crossing is an existing river crossing located within a public right-of-way in Madera County and on private land in Fresno County at approximately RM 211.8. The crossing transitions from public right-of-way to private land at the center of the river. The crossing consists of a low flow or dip crossing with a single culvert. As

part of this alternative, the culvert and road embankments would be demolished, and no river crossing would be provided at this location.

Compact Bypass Bifurcation Structure

A bifurcation structure would be constructed at the upstream end of the Compact Bypass. The bifurcation structure consists of two control structures: one across the path of Restoration Flows (Compact Bypass) and one across the path of water deliveries to Mendota Pool (San Joaquin River). Since this structure will be retaining the Pool, it would likely be regulated by DSOD if owned by a State or local entity.

The control structure across the Compact Bypass would be designed to accommodate up to 4,500 cfs and consists of six 20-foot-wide bays for a structure length of approximately 140 feet. Conditions in this control structure would be designed based on NMFS 2001 and NMFS 2008 fish passage criteria. The control structure across the San Joaquin River (the path of the water deliveries) would be designed to accommodate up to 2,500 cfs and consists of four 20-foot-wide bays for a structure length of approximately 100 feet. Flow through each bay would be controlled by a gate (e.g., radial [Tainter] or inflatable Obermeyer). In the final design, the number and size of the gates may be modified. The size of the gates would be determined by the design maximum flow.

The Compact Bypass control structure includes a fish passage facility on the side of the structure (i.e., the Compact Bypass Fish Passage Facility), and the San Joaquin River (water deliveries flow path) control structure includes a fish screen upstream of the structure (i.e., the Mendota Pool Fish Screen), if appropriate. Each control structure would be placed in the middle of the channel and has earthen embankments connecting the structure to the proposed levees. The connector embankments may include culverts, gates, weirs, inflatable bladder dams, or other features to improve flow and fish passage on the floodplain when water deliveries are not occurring. A 16-foot-wide roadway and 20-foot-wide maintenance/operations platform would be provided over each control structure.

Compact Bypass Fish Passage Facility

The Compact Bypass control structure (across the Restoration Flow path) includes a fish passage facility. The fish passage facility would be necessary to provide passage during water deliveries and for Restoration Flows where passage conditions in the control structure may not be ideal. The design of the fish passage facility is the same as that presented above for the fish passage facility at San Joaquin River control structure at the Chowchilla Bifurcation Structure.

Drive 10 ½ Crossing

The Compact Bypass would cross existing Drive 10 ½, which provides access for the operations and maintenance of Mendota Dam. To continue the current level of access, the road would be rerouted along the bypass channel levees and cross the head of the bypass channel at the proposed Compact Bypass bifurcation structure. A road deck would also be provided over the fish passage facility adjacent to the bifurcation structure. The road would be designed for HS-20 loading (e.g., sufficient to allow transport of a 25-ton maintenance crane to Mendota Dam).

Mendota Pool Fish Screen

A fish screen would be included adjacent to the head of the Compact Bypass where water deliveries would be diverted from the river to Mendota Pool, if appropriate.[7] The fish screen would keep or return out-migrating juvenile salmon to the Compact Bypass (the path of Restoration Flows) during water deliveries. The Compact Bypass Bifurcation Structure is only operated for Exchange Contractor diversions in summer months in highly infrequent dry years or during flood flow deliveries, when flows split several times before entering Mendota Pool and fish survival through the bypasses is high. The Mendota Pool fish screen is the same as described for the South Canal in Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5.

The screen would be designed to pass flow up to 2,500 cfs. The type of fish screen could be a fixed flat plate in "V" configuration, vertical flat plate, inclined flat plate, cone, or cylindrical screens. Depending on the design type, the fish screen facility may include trash racks, stainless steel wedge wire fish screens, flow control baffle systems behind the screens, screen cleaning systems for the trash racks and screens, bypass flow control weirs, fish-friendly pumps, and/or fish bypass pressure pipelines. The trash racks would be installed at the entrance to the screen structures to protect screens from trash, logs, and other large debris.

Approach, sweeping, and bypass entrance velocities would be kept within established fish screen criteria (NMFS 2008). Flow through the fish screens may be controlled by baffles behind the fish screens. Cleaning of the screens would be accomplished using an automated brush system. Electric power would be needed for fish friendly pumps, if included, and screen cleaning systems. Operation of the fish screens would include methods to reduce predation of juvenile fish (e.g., noise systems to scatter predators, netting, and periodic draining of the screen return pipes).

Grade Control Structures

A series of several (2 to 6), approximately 1.0-foot-high grade-control structures could be included within the bypass channel to achieve the necessary elevation change between Reach 2B and Reach 3, if necessary. The grade control could be provided by constructed rock riffle structures stabilized with sheet piles.

Rock riffles have benefits for native fish migration, but they present construction challenges in the sandy substrate of the Reach 2B and Reach 3 area. The flow over constructed rock riffles may reduce the disorienting effects on juveniles from rapidly changing hydraulics otherwise created at weir structures, and they are more favorable to sturgeon, which do not jump. Constructed rock riffles may be less favorable to predators which can hold in the quiescent pools below weir structures. However, placing rock in sandy substrate requires engineered foundation materials (layers of rock in gradually decreasing sizes) to prevent undermining the structure. Further analysis during design will determine the rock sizes and riffle slopes.

[7] The need for the Mendota Pool fish screen will be further evaluated as Project planning and design continues. This screen is included in Alternative B in the event that it is determined necessary.

Sheet piles would be installed on the upstream side of each rock riffle. Caps on the sheet piles would be used to avoid injuring fish and can be surfaced with natural materials (i.e., grouted rock) to emulate natural conditions which fish may be exposed to in non-manmade portions of the San Joaquin River.

Each grade control structure would extend across the main channel and key into the overbanks to protect against flanking, resulting in a total structure width of about 220 feet.

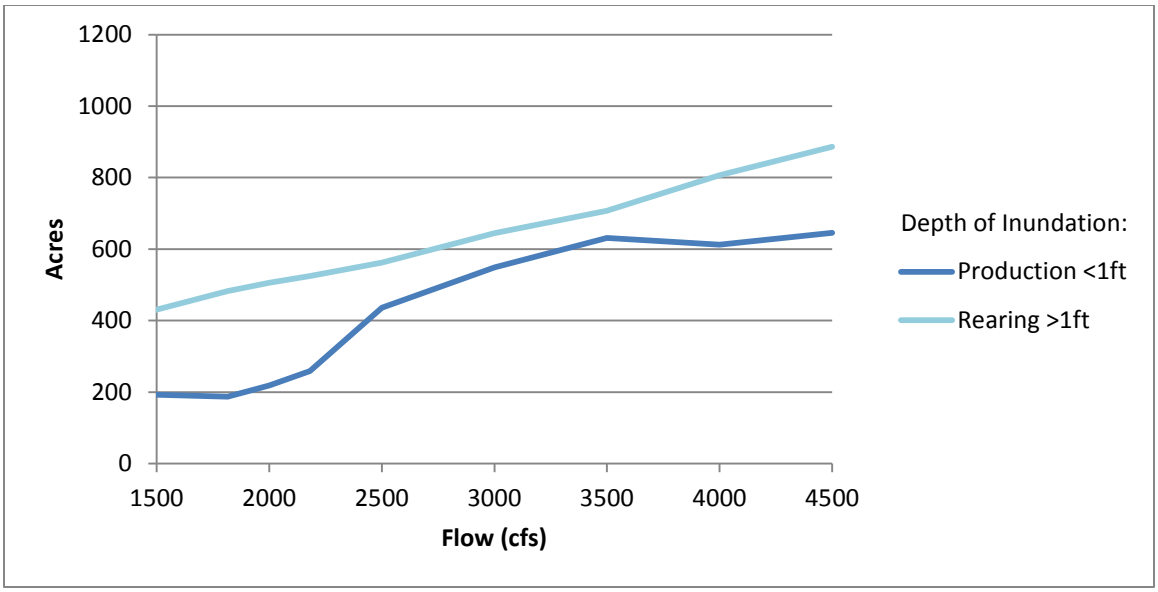
Bank protection measures would be incorporated into the bypass. Bank protection measures could include: vegetated revetment, rock vanes, large woody material structures, bioengineering techniques, and riparian vegetation. Bank protection could be included in the channel, along one channel bank, or along both channel banks. It is assumed that the vegetated revetment would consist of buried riprap covered with topsoil, erosion control fabric, and native woody vegetation, so that fish would experience natural channel banks. Rock vanes would be constructed to only interact with the flow if erosion occurs (i.e., the top of the vane will be level with the constructed overbank surface). Large woody material structures are assumed to be anchored engineered logjams or other similar anchored wood structures that are built into the channel banks. Bioengineering techniques could include vegetated geogrids, fabric encapsulated soil banks, brush mattresses, and root wads. Native woody vegetation directly upstream, downstream, and adjacent to the grade control structures would provide shading and opportunities for juveniles to hide from predators.

Fish Habitat and Passage

The purpose of the floodplain would be to provide riparian and floodplain habitat and support the migration and seasonal rearing of salmonids and other native fishes in Reach 2B. Floodplains would be developed in accordance with the Rearing Habitat Design Objectives. The floodplain has an average width of approximately 4,200 feet and an inundated area of approximately 1,000 acres at 2,500 cfs.

This alternative provides floodplain habitat resulting in approximately 440 acres of shallow water habitat for primary production as well as approximately 560 acres of habitat that supports direct rearing at 2,500 cfs. Approximately 44 percent of the floodplain in this alternative would inundate less than 1 foot deep at 2,500 cfs. This alternative also retains approximately 650 acres of shallow water habitat at flows of 4,500 cfs. Figure 2-12 below presents conceptual inundation areas for primary production and rearing habitats as they vary by flow. Inundation acreages may change during the design process.

In the Compact Bypass channel, floodplain benches with an approximate average width of 150 feet on each side the main flow portion of the bypass channel are included (see section “Compact Bypass Channel.”) Riparian and floodplain habitat would be planted and developed on the benches in the bypass channel to benefit migrating fish and promote a stable channel and sediment transport from Reach 2B to Reach 3.



Source: Reclamation 2015

Figure 2-12.
Potential Inundation Acreage by Flow for Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure)

This alternative includes several facilities that fish may encounter or need to pass to migrate between Reach 3 and Reach 2B (from downstream to upstream):

- Several (2 to 6) in-channel grade control structures in the Compact Bypass.
- Four fish screen return outlets from the Mendota Pool fish screen.
- A bifurcation control structure at the upstream end of the Compact Bypass with fish passage facility.
- The Mendota Pool fish screen adjacent to the upstream end of the Compact Bypass.
- Fish screens at Lone Willow Slough, Big and Little Bertha pumps, and other smaller diversions, if determined necessary (these screens are discussed in Section 2.2.4).
- The San Joaquin River control structure at the Chowchilla Bifurcation Structure with a fish passage facility.

Each structure would be designed to perform according to the fish passage design criteria (see Section 2.2.4). In addition, the channel and floodplain incorporate riparian plantings to provide cover, woody material, and velocity variability, while the design footprint allows sufficient space to incorporate channel structure variability during detailed design, all of which may help to reduce stress and predation.

This alternative does not include a fish barrier at the downstream end of the Compact Bypass to keep fish from migrating upstream of the Compact Bypass in Reach 3 toward the base of Mendota Dam.

Floodplain and Riparian Habitat

This alternative includes a mixture of active and passive riparian and floodplain habitat restoration (in contrast to the passive restoration included in Alternative A) and compatible agricultural activities in the floodplain. Active restoration planting of native riparian species would occur along both banks of the low flow channel of the river up to 450 feet from the bank. In accordance with the Rearing Habitat Design Objectives, it would include native species that would provide shade and reduce air temperatures to help minimize water temperatures, provide large woody debris and organic matter needed to provide habitat and food, and help stabilize the low-flow channel. Some areas may be passively revegetated by creating riparian establishment areas that provide a riparian seed bank of native species. The remaining areas would be seeded with native grasses and forbs to minimize erosion and to help control invasive species. Active revegetation activities would likely include a combination of seeding, transplanting, and pole/live stake plantings. Plantings may be designed as either clusters of trees and shrubs with larger areas of seeded grasses and forbs or as dense forests. Spacing and alignment of plantings would take into account species growth patterns, potential equipment access needs for monitoring and maintenance, and desired future stand development. Passive restoration would occur in areas that rely on Restoration Flows for additional vegetation recruitment. Natural riparian recruitment (passive restoration) would promote continual habitat succession, particularly in areas where sediment is deposited or vegetation is removed by natural processes.

Table 2-3 lists the species that are likely to be planted or seeded during active restoration, and is draft and subject to change. Emergent wetlands and water tolerant woody species of riparian scrub would be selected for development within the main channel, woody shrubs and trees with an herbaceous understory would be selected for development along the main river channel banks, and bands of other habitat types (e.g., grasses) would be selected for development at higher elevations along the channel corridor. Active vegetation restoration would occur following construction and these areas would be irrigated and managed as necessary during the establishment period. Phased implementation of active vegetation restoration at strategic locations could occur concurrently with phased implementation of construction and physical infrastructure.

Agricultural practices (e.g., annual crops, pasture, or floodplain-compatible permanent crops) could occur on the floodplain in previous agricultural areas outside of State-owned and public trust lands. Growers would be required to leave cover on the ground and would be required to develop and implement a Water Quality Plan, approved by the Reclamation, to meet current water quality standards for aquatic resources and coldwater fisheries, as well as meeting the specific needs for anadromous fishes in adjacent and downstream areas.

Table 2-3.
Potential Species for Revegetation

Common Name	Scientific Name	Vegetation Type
Riparian Shrub and Wetland Areas (0 to 2 feet above summer baseflow elevations)		
Gooding's willow	*Salix gooddingii*	tree
common buttonbrush	*Cephalanthus occidentalis*	shrub
narrowleaf willow	*Salix exigua*	shrub
redroot flatsedge	*Cyperus erythrorhizos*	annual sedge
baltic rush	*Juncus balticus*	perennial rush
dwarf barley	*Hordeum depressum*	annual grass
spike bentgrass	*Agrostis exarata*	perennial grass
meadow barley	*Hordeum brachyantherum*	perennial grass
distant phacelia	*Phacelia distans*	annual forb
seep monkeyflower	*Mimulus guttatus*	annual/perennial forb
yerba mansa	*Anemopsis californica*	perennial forb
Douglas' sagewort	*Artemisia douglasiana*	perennial forb
Dense Riparian Areas (2 to 8 feet above summer baseflow elevations)		
white alder	*Alnus rhombifolia*	tree
Oregon ash	*Fraxinus latifolia*	tree
California sycamore	*Platanus racemosa*	tree
Fremont cottonwood	*Populus fremontii*	tree
Gooding's willow	*Salix gooddingii*	tree
mule-fat	*Baccharis salicifolia*	shrub
California wildrose	*Rosa californica*	shrub
narrowleaf willow	*Salix exigua*	shrub
dwarf barley	*Hordeum depressum*	annual grass
spike bentgrass	*Agrostis exarata*	perennial grass
meadow barley	*Hordeum brachyantherum*	perennial grass
Douglas' sagewort	*Artemisia douglasiana*	perennial forb
Upland Areas (greater than 8 feet above summer baseflow elevations)		
cattle saltbush	*Atriplex polycarpa*	shrub
California wildrose	*Rosa californica*	shrub
Saltgrass	*Distichlis spicata*	perennial grass
blue wildrye	*Elymus glaucus*	perennial grass
beardless wildrye	*Leymus triticodes*	perennial grass
California goldfields	*Lasthenia californica*	annual forb
bull clover	*Trifolium fucatum*	annual forb

Existing Native Vegetation Protection

The existing native vegetation in the Project area designated to remain would be temporarily fenced with orange snow fencing (or equivalent) to prevent entry, driving, parking, or storing equipment or material within these areas during construction. Existing vegetation would be left in place or only minimally trimmed to facilitate access and work at the site. The existing soil is an ideal growing medium for all the desired native plants. In order to maximize plant growth and planting success, existing soil and topsoil would

be preserved unless the soil contains invasive non-native seed or fragmented stems and rhizomes, in which case it should not be preserved, and disturbance during construction would be minimized to the maximum practicable extent.

Invasive Species Control

Invasive, non-native species would be removed from the Project area during the installation, plant establishment and maintenance periods. Invasive species management would consist of removal of the most invasive non-native species within the reach such as giant reed grass (*Arundo donax*), perennial pepperweed (*Lepidium latifolium*) and poison hemlock (*Conium maculatum*). Invasive species management would also include removal of other invasive species that are currently found in upstream reaches and may eventually colonize in the Project area such as red sesbania (*Sesbania punicea*), salt cedar (*Tamarix species*), and Chinese tallow (*Sapium sebiferum*). Invasive plant removal techniques may include mechanical removal, root excavation, hand pulling, mowing, disking, controlled burning, grazing, aquatic-safe herbicides, or a combination of techniques as appropriate.

Temporary Irrigation System and Water Supply

Proposed plantings that are wetland species or borderline wetland species would need regular aboveground irrigation (typically April through October) during their establishment period (typically 3 to 5 years depending on rainfall conditions and the plants' growth rates and vigor). The amount of water needed is estimated to be approximately 2.4 acre feet per year. An extensive temporary aboveground irrigation system, such as aerial spray or drip irrigation, would provide water for the plants several times a week during the hot months of the year. If an aerial spray irrigation system is installed, the irrigation distribution piping would be installed aboveground and anchored to the ground so that it would not be damaged during high flows inundating the floodplain. If an aerial spray system is used, sprinkler heads would likely be installed on braced standpipes so that their irrigation stream would not be blocked or diverted by growing vegetation. The irrigation system would be disassembled and removed at the end of the establishment period.

The Program would pursue options for irrigation water supply, including groundwater wells or water pumped from the river with portable, skid-mounted, diesel- or gas-powered pumps and stored in tanks. Additionally, purchases from willing sellers may be required to withdraw water from the river or other nearby water sources (e.g., Mendota Pool). If water is pumped from the river, the amount of water diverted will be controlled so that river water temperatures do not increase and passage for salmonids is not impaired. The diversion from the river would also be screened if necessary to prevent entraining juvenile salmonids.

Maintenance and Monitoring

Maintenance and monitoring would be conducted following revegetation. Monitoring activities include monitoring of the installed plants for drought stress and overwatering, identification of competitive, invasive, non-native species for removal, identification of diseased, dead and washed-out plants, irrigation system function, and identification of trash and debris for removal. Maintenance activities would include controlling invasive plant species, mitigating animal damage, irrigation, replacement of diseased, dead, or

washed-out plants, irrigation system maintenance, and removal of trash and debris. Management of invasive species would ensure that the desirable vegetation dominates the landscape and provides habitat diversity, productivity, and sustainability. Animal damage to newly planted or germinated vegetation could be alleviated with screens, aquatic-safe chemical deterrents, or other exclusion methods.

Temporary irrigation of wetland and riparian areas during establishment, especially if precipitation is below normal, would facilitate root system development into the alluvium groundwater. Irrigation infrastructure would need to be installed and remain in place for at least 3 years. The irrigation system would be used each year on a biweekly to daily basis during the hot part of the growing season. The landscape contractor would be required to regularly check the integrity of the system and make sure that system is not clogged or damaged. Upland areas would be seeded in the fall before the winter precipitation season, and it is likely that these areas would become established to an acceptable level after one season of normal precipitation. (There may be more than one active revegetation effort required to establish a dense riparian corridor necessary to naturally stabilize the Compact Bypass channel.) Removal of trash and debris from the restoration areas on both sides of the river would be performed on an as-needed basis for the duration of the entire monitoring period.

Long-Term Management

While it is not anticipated that major management actions would be needed, the key objective of management would be to monitor and identify any environmental issues that arise, and use adaptive management to determine what actions would be most appropriate to correct these issues.

The general management approach to the long-term maintenance of the floodplain areas would be to maintain quality habitat for each natural resource, on-going monitoring and maintenance of key environmental characteristics of the entire floodplain area within the reach. An adaptive management approach would be used to incorporate changes to management practices, including corrective actions as determined to be appropriate by Reclamation and/or CSLC. Adaptive management includes those activities necessary to address the effects of climate change, fire, flood, or other natural events, force majeure, etc.

The expected long-term management needs and activities necessary to maintain any on-site mitigation sites would be resource specific long-term maintenance activities and other general maintenance activities such as exotic species elimination, grazing management, clean-up and trash removal, infrastructure management such as gate, fence, road, culvert, signage and drainage-feature repair, and other maintenance activities necessary to maintain the riparian and floodplain habitat quality.

Water Deliveries

This alternative includes a diversion at the head of the Compact Bypass for making up to 2,500 cfs in water deliveries from the San Joaquin River to Mendota Pool. This diversion would directly deliver water from the river to Mendota Pool without the need for a canal. Water deliveries to the Pool would include diversion of Friant Dam releases that are

meant to satisfy the Exchange Contract as well as diversion of San Joaquin River flood flows up to 2,500 cfs if there is demand in Mendota Pool.

When water deliveries occur, the gates at the Compact Bypass bifurcation structure would be manipulated to control flows into the Compact Bypass and allow flows into Mendota Pool. Since the Mendota Pool operating elevation is several feet higher than the bottom of the Compact Bypass channel, operation of the gates would include backwatering a portion of the San Joaquin River upstream of the Compact Bypass bifurcation structure. The extent of the backwater is anticipated to be similar to the extent of the Mendota Pool backwater under existing conditions (i.e., upstream to approximately the existing San Mateo Avenue crossing). Up-migrating fish passage from the Compact Bypass into Reach 2B would occur through the Compact Bypass fish passage facility during water deliveries. The Mendota Pool fish screen would capture out-migrating fish entering the diversion and return them to the Compact Bypass. Sufficient flow to support adult and juvenile fish passage through the Compact Bypass would be maintained during water delivery operations during fish migration periods.

Construction Considerations

The total construction timeline for this alternative is currently estimated to range approximately from 106 to 157 months (9 to 13 years); opportunities to shorten the overall schedule through construction efficiencies will be studied during the detailed design process.

Soil improvements for possible liquefiable soils may be required to protect proposed structures from damage or failure during an earthquake. All proposed structures would be designed to account for potential liquefaction. Soil improvements could include removing and replacing soils with adequate materials, injecting soil-cement slurry, vibrofloatation, dynamic compaction, structural foundation piles (stone or reinforced concrete), and other techniques.[8]

Flow in the San Joaquin River, operations at the existing Mendota Dam, operations at the Chowchilla Bifurcation Structure, and operation of the existing Columbia Canal must be maintained during construction. The majority of the Compact Bypass channel would likely be constructed without interruption to the San Joaquin River flow or the Columbia Canal.

The construction of the Mendota Pool control structure across the existing river channel would require removable cofferdams in three phases to facilitate the construction without blocking the flow. If flow is present in the river during the construction period, flow would be diverted around the work area via a temporary diversion pipe or canal and fish passage would be provided. Cofferdams include two rows of braced sheet piling filled with dirt for stability and seepage control. The total height of the cofferdam is assumed to be 24 feet of which 12 feet would be above the channel bed. The control structures to be

[8] Vibrofloatation uses a vibrating probe that penetrates the soil and causes the grain structure to collapse and increase the density of the soil. Dynamic compaction involves dropping a heavy weight onto soil to compact it.

constructed on dry land (e.g., the Compact Bypass control structure) would not require cofferdams.

Stone slope protection (riprap) would be provided on the upstream and downstream slopes of the control structure embankment including some portions of the side slopes of the channel itself to prevent scouring. Riprap would be placed on bedding over geotextile fabric.

Construction of the fish screen, which is located in the San Joaquin River, would require removable cofferdams in three phases to facilitate the construction without blocking the flow. The exception to this is the return/bypass fish pipes and outlet, which would take place in the dry using conventional construction methods. All fish facility structures and pipes with surfaces exposed to fish require additional attention to surface-smoothness.

For construction of the control structures and fish passage facilities, it would be desirable to maintain a minimum flow during construction; the amount or range of flows during construction has not yet been identified. For construction at the bifurcation, it was assumed that construction would first be done away from the fish passage facility. A sheet pile cofferdam would be provided for the Mendota Pool control structure and/or the Compact Bypass control structure, if needed, and the water diverted away from the construction. Additional sheet piling would be provided to divert flows through the new bifurcation structure while the fish passage facility is constructed.

Demolition of the San Mateo Avenue crossing would be timed so that the lesser Restoration Flows (5 to 195 cfs) can be routed around the structure during demolition.

Summary

Table 2-4 summarizes the levees, relocations, land acquisition, and construction schedule associated with Alterative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure) based on design, field, and evaluation criteria data prepared for the EIS/R.

Table 2-4.
Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure)
Levees, Relocations, and Land Acquisition

	Left Levee	Right Levee
Levee Length	8.1 miles	6.8 miles
Average Levee Height	5.6 feet	4.7 feet
Fill Volume	328,600 cubic yards	226,900 cubic yards

Relocations			
Electrical Distribution	48,500 feet	Barn/Shed	1
Gas Transmission	11,000 feet	Facility	1
Water Pipeline	41,000 feet	Groundwater Well	32
Canal	31,500 feet	Lift Pump	10

Table 2-4.
Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure)
Levees, Relocations, and Land Acquisition

Culvert	1	Power Pole	162
Diversion	3	Dwelling	2
Land Acquisition and Construction Schedule			
Land Acquisition[1]	2,900 acres		
Time to Build[2]	157 months		

[1] Total acreage includes areas that are sovereign and public trust lands.

[2] Construction timeline does not include the time that would also be needed to complete the NEPA and CEQA documentation process, obtain permits, appraise and acquire land, and perform pre-construction surveys.

2.2.7 Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal) includes:

- Building levees capable of conveying flows up to 4,500 cfs with 3 feet of freeboard.
- Restoring floodplain habitat an average of approximately 3,000 feet wide to provide benefit to salmonids and other native fishes.
- Constructing a dam capable of containing Mendota Pool within Fresno Slough so that 4,500 cfs of Restoration Flows can be conveyed around the Mendota Pool.
- Constructing the Short Canal and structures capable of conveying up to 2,500 cfs from Reach 2B to Mendota Pool.
- Providing upstream and downstream fish passage for adult salmonids and other native fishes, and downstream fish passage for juvenile salmonids, between Reach 2A and Reach 3.

This alternative would build a dam across Fresno Slough, the Fresno Slough Dam, to contain the Mendota Pool, and it would utilize the existing river channel in order to bypass the Mendota Pool. Restoration Flows would enter Reach 2B at the Chowchilla Bifurcation Structure, flow through Reach 2B, then downstream to Reach 3 over the sill at Mendota Dam. Mendota Pool would be contained south of the Fresno Slough Dam. The existing Chowchilla Bifurcation Structure would continue to divert San Joaquin River flows into the Chowchilla Bypass during flood operations, and a fish passage facility and control structure modifications would be included at the San Joaquin River control structure at the Chowchilla Bifurcation Structure. A canal to convey San Joaquin River water deliveries to Mendota Pool, the Short Canal, would be built adjacent to the Fresno Slough Dam. The Mendota Dam along with a control structure built at the head of the Short Canal would be used to control diversions into Mendota Pool through the Short Canal. Fish passage facilities at Mendota Dam and a fish screen on the Short Canal would be built to provide passage around Mendota Dam and prevent fish from being entrained

in the diversion. A fish barrier would be built downstream of the Fresno Slough Dam to keep up-migrating fish in Reach 2B. A new crossing would be built at the San Mateo Avenue crossing. These features are described in further detail in the sections below. See Figure 2-13 and Figure 2-14 for a plan view of the alternative's features.

Short Canal

The Short Canal would deliver up to 2,500 cfs in water deliveries from the San Joaquin River to Mendota Pool. The Short Canal could connect to the river either on the east or west side of the Fresno Slough Dam. Additionally, the west-side configuration could be combined with the Main Canal and Helm Ditch Relocations or be constructed independent of those relocations. The Short Canal would discharge into Fresno Slough approximately 0.8 river mile south of Mendota Dam.

Water deliveries would be controlled by a control structure at the north end of the Short Canal and Mendota Dam. The canal control structure would have a fish screen to prevent entrainment and Mendota Dam would be retrofitted with fish passage facilities. The control structures, fish screen, and fish passage facilities are discussed under Structures.

The Short Canal would be concrete-lined with a trapezoidal cross-section. The Short Canal would have a top-width of approximately 70 feet, a total corridor width of approximately 180 feet (including levees and maintenance roads), and 2H to 1V side slopes on the canal banks and 3H to 1V side slopes on the levees. Levee heights would be based on a flow of 2,500 cfs and 3 feet of freeboard.

Structures

The structures described below would be required to provide the operational flexibility to divert water to the Mendota Pool, provide fish passage, prevent fish entrainment and straying, and provide controlled elevation drop between Reach 2B and Reach 3.

Fish Passage Facility on the San Joaquin River Control Structure at the Chowchilla Bifurcation Structure

The fish passage facility is the same as that in Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure) in Section 2.2.6.

San Joaquin River Control Structure at the Chowchilla Bifurcation Structure Modifications

The San Joaquin River control structure at the Chowchilla Bifurcation Structure modifications is the same as described in Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure) in Section 2.2.6.

San Mateo Avenue Crossing Replacement

The existing river crossing at San Mateo Avenue would be replaced with a new culverted crossing. The crossing is the same as described in Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5.

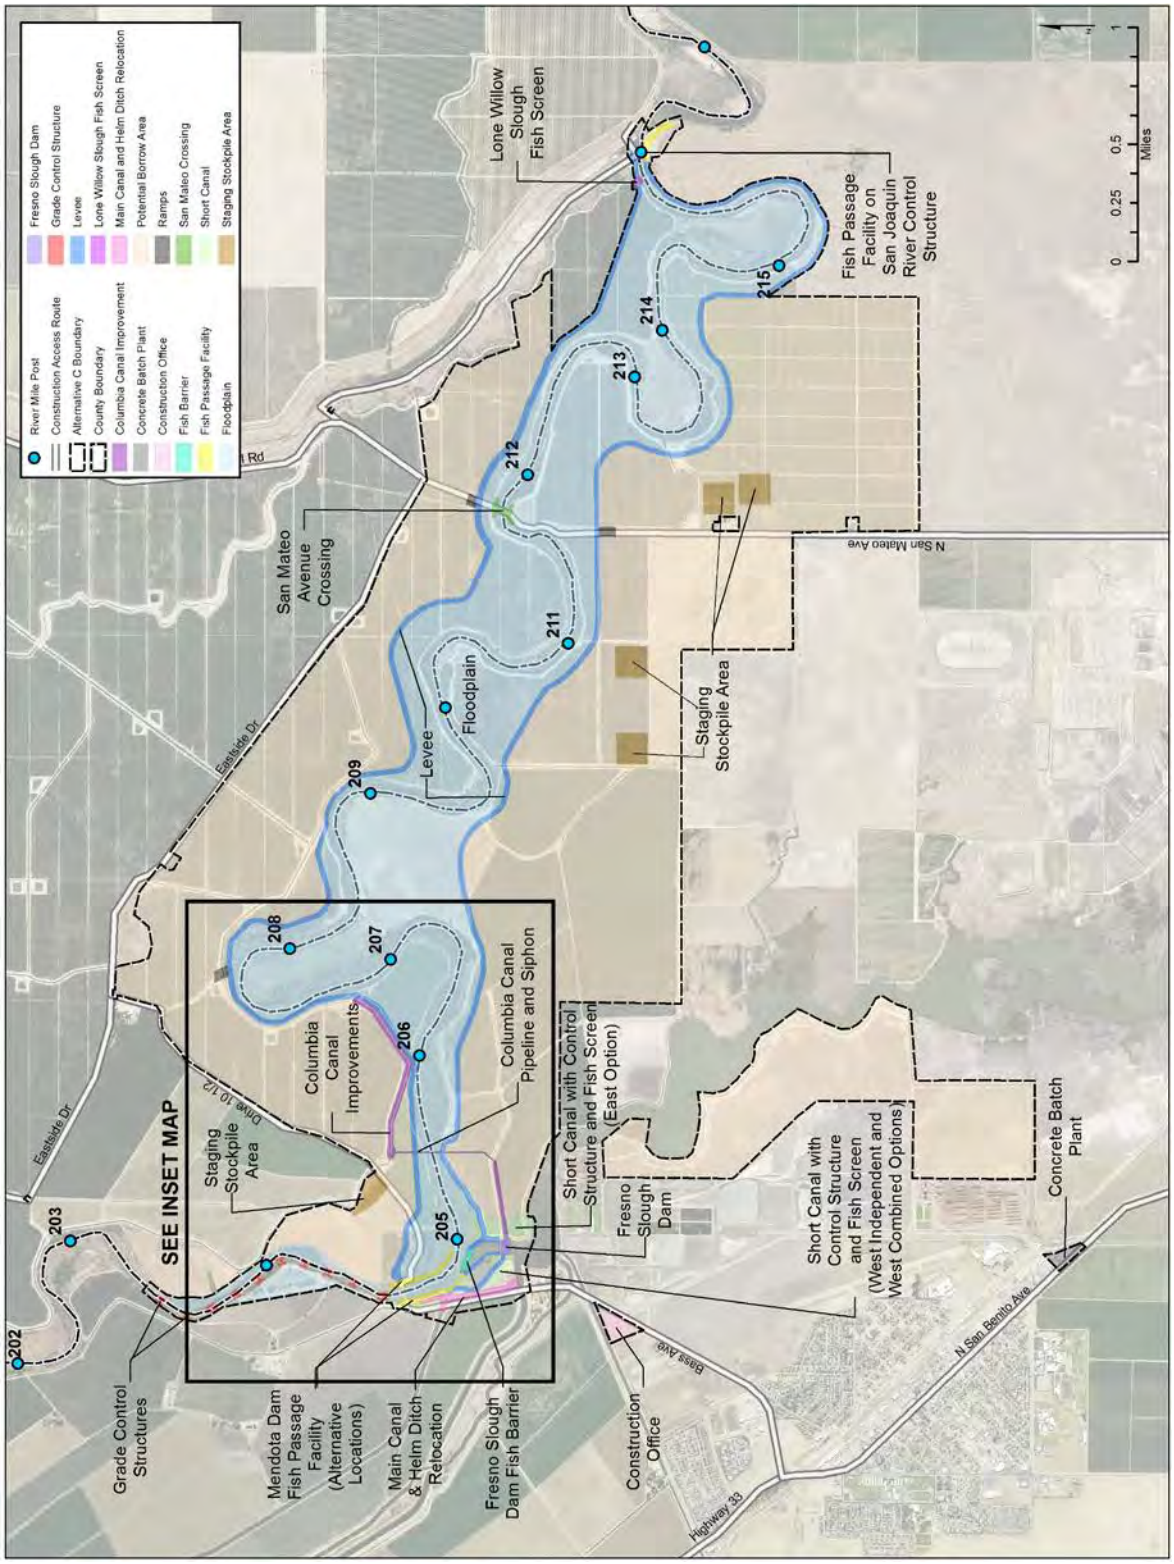


Figure 2-13.
Plan View of Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

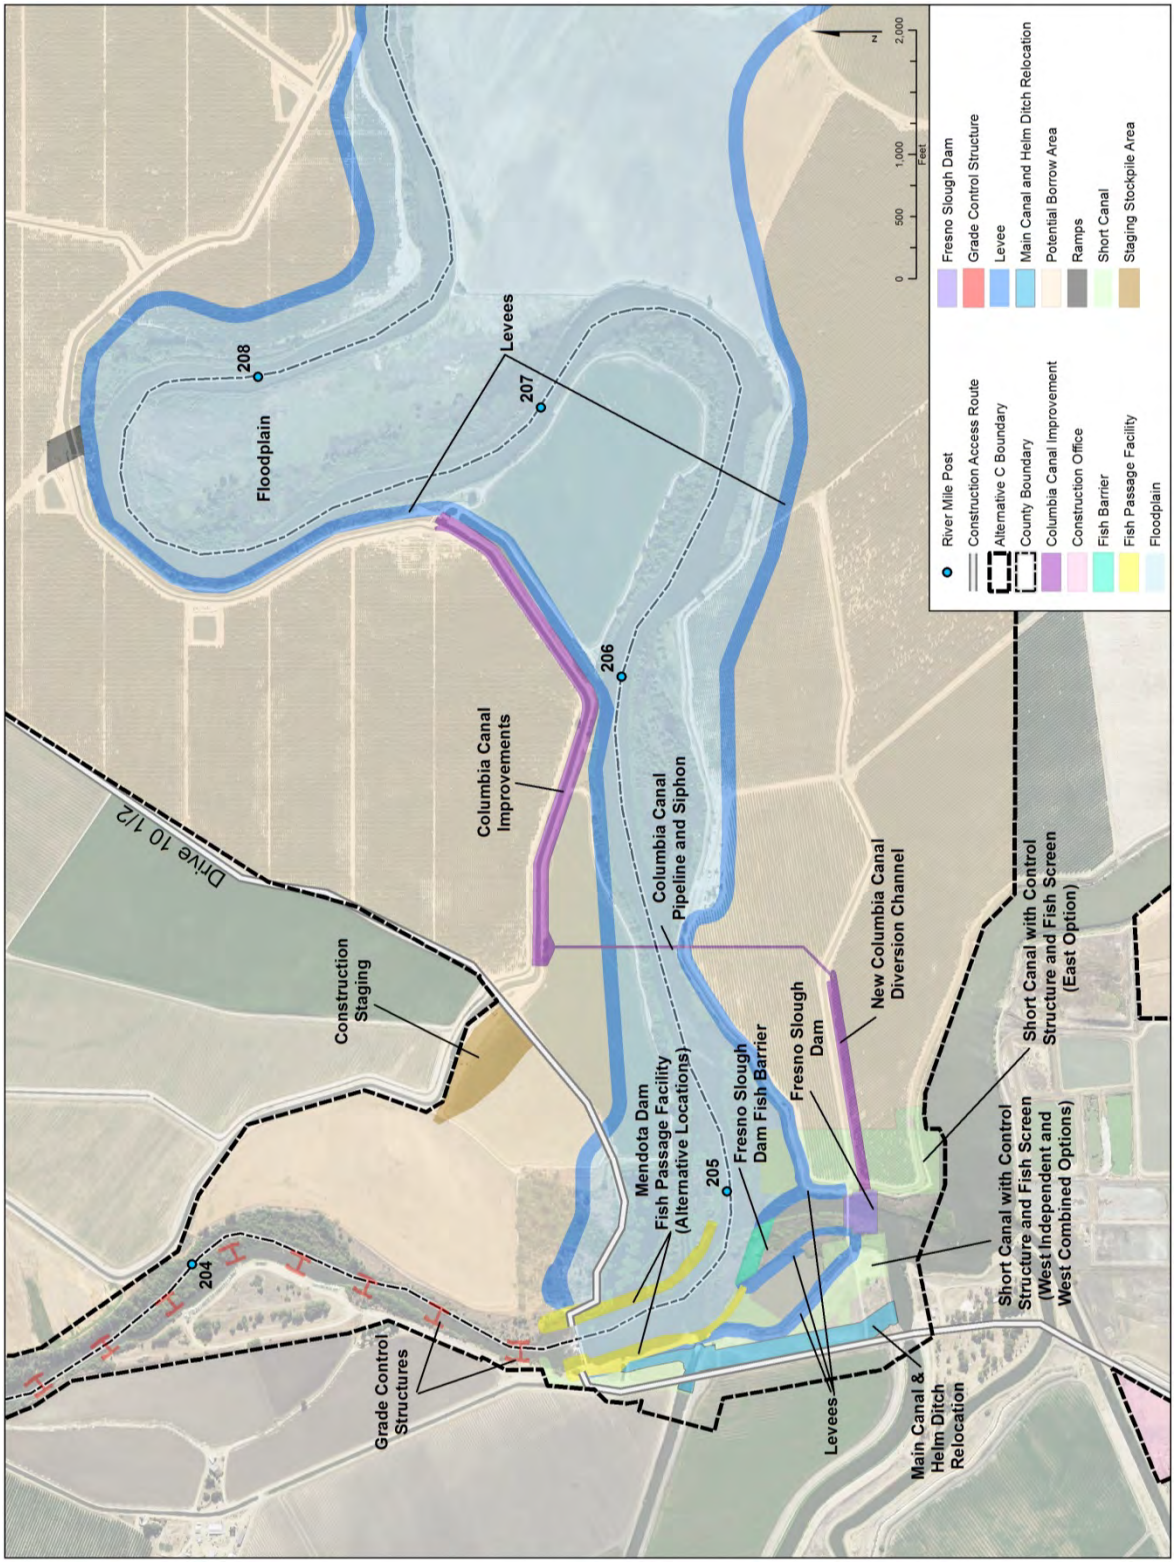

Figure 2-14.
Inset Map of Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Short Canal Control Structure

A control structure would be constructed at the upstream end of the Short Canal. The control structure would be across the path of water deliveries to Mendota Pool. Since this structure will be retaining the Pool, it would likely be regulated by DSOD if owned by a State or local entity. The Short Canal control structure is the same as the control structure across the path of water deliveries described for Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5.

Short Canal Fish Screen

A fish screen would be included at the head of the Short Canal where water deliveries would be diverted from the river. The fish screen would be necessary to keep or return out-migrating juvenile salmon to the San Joaquin River (the path of Restoration Flows) during water deliveries. The Short Canal fish screen is the same as described for the South Canal in Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5.

Fresno Slough Dam

The Fresno Slough Dam would be constructed approximately 0.5 mile south of the Mendota Dam, in the existing Fresno Slough. In addition, the dam structure would be located just south of the existing Mowry Bridge that crosses the Fresno Slough. The dam would serve to limit the extent of Mendota Pool so it no longer occupies portions of the San Joaquin River. This pool would feed the five existing irrigation canals (Main Canal, Helm Ditch, Columbia Canal, Outside Canal, and Main Lift Canal). A screened water diversion canal would enable water deliveries from the San Joaquin River to the Mendota Pool. Since inputs into the Mendota Pool would be screened, Fresno Slough Dam does not require provisions for fish passage. Since this structure will be retaining the Pool, it would likely be regulated by DSOD if owned by a State or local entity.

The dam structure would be designed to accommodate a maximum water elevation of 156 feet. This water elevation corresponds to a pool depth of 16 feet above the top of the concrete floor.

The Fresno Slough Dam would have a reinforced concrete spillway. The spillway would likely not require the support of piles. The spillway would include a concrete cutoff wall at the upstream end of the spillway to limit the hydrostatic uplift pressures and reduce the effects of scour. Baffle blocks and riprap would be included at the downstream end of the concrete spillway to limit the effects of scour and erosion.

Directly adjacent to the upstream and downstream ends of the concrete dam structure, a total of four concrete retaining walls form the walls of the spillway, and retain the sides of the earthen embankment portion of the dam. The spillway structure would be comprised of multiple gates, which serve to control the flow of water from the Mendota Pool to the San Joaquin River.

Over the dam, a concrete roadway, concrete maintenance platform, and a hoist operation platform span the full width of the structure. A series of vertical stoplog slots would be included in the concrete abutment walls. The stoplog slots allow the placement of

stoplogs directly upstream of the gates, to facilitate local dewatering of the gates for maintenance operations.

Some excavation of existing channel sediments upstream of the dam will be required to improve flow conditions through the dam during Kings River floods.

Fresno Slough Dam Fish Barrier

A fish exclusion barrier would be included north of the Fresno Slough Dam to prevent adult fish from migrating into Fresno Slough during Kings River flood releases through the Fresno Slough Dam. Levees would be constructed to delineate a channel between the Fresno Slough Dam and the fish barrier, and sediments in the San Joaquin River would be excavated to allow proper structure placement and acceptable sweeping velocities.

The design of the fish barrier is the same as the Reach 3 fish barrier described for Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5.

Mendota Dam Modifications

This alternative includes using the San Joaquin River channel as a means of bypassing Mendota Pool. Since the Mendota Dam crosses the San Joaquin River, the structure will need to be modified to provide run-of-the-river conditions during Restoration Flows. The concrete portions of structure of Mendota Dam would remain in place, and the flash boards currently used to close the bays and back up water would be removed during non-water delivery operations using the Short Canal. The sill of the dam may be notched in one or more bays to improve fish passage conditions, and the notch would be designed to accommodate flash boards similar to the current bays. When the Short Canal is in operation, the flash boards would be placed in the notch(es) and bays to back up water for water deliveries.

Mendota Dam Fish Passage Facilities

Fish passage facilities are provided at Mendota Dam for two conditions: when the boards are out and when the boards are in. Most of the time, the flash boards at Mendota Dam will be out, and Restoration Flows will pass unimpeded over the sill at Mendota Dam. When water deliveries from the river to Mendota Pool are occurring, the flash boards at Mendota Dam will be installed to create an impoundment. Due to the variation in conditions, different fish passage facilities are required for each condition.

Boards-Out Conditions (no water deliveries occurring)

Passage for boards-out conditions could be accomplished with either grade-control structures, dam notching, a fish passage facility, or a combination of these.

A series of approximately 0.5-foot-high grade control structures could be installed downstream of Mendota Dam to increase the water surface elevation during low flows of around 100 cfs to allow fish passage over the sill when the boards are out at Mendota Dam. The structures would be located several hundred feet apart. Each structure would raise the water surface incrementally on the downstream side of the dam so that

salmonids would be able to migrate over the sill. Other aspects of the grade control structures are the same as those described for those in Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5.

The sill of the dam could also be notched to provide suitable low flow passage conditions when the boards are out. Notching the dam would involve removing portions of the existing concrete sill and potentially reinforcing the remaining concrete. The notch(es) would be designed to accommodate flash boards so that water delivery operations could occur. Notching could be utilized in combination with the grade control structures to reduce the overall number of structures needed to incrementally raise the water surface on the downstream side of the dam.

Alternatively, a fish passage facility could be installed at Mendota Dam to provide passage when the boards are out. The boards-out fish passage facility could be combined with the boards-in fish passage facility (described below) by including multiple entrances and exits on the facility. Otherwise, an independent fish passage facility for boards-out conditions could be constructed. The design of the boards-out fish passage facility is the same as described for the South Canal fish passage facility in Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5.

Boards-In Conditions (during water deliveries)

For the Short Canal to operate, the boards at Mendota Dam would be replaced to raise the water surface in the river and back up water into the Mendota Pool. A proposed fish passage facility enables fish to pass over Mendota Dam when the boards are in. The passage facility transitions from the minimum San Joaquin River water surface elevation in Reach 3 (occurring during low flow/base flow conditions) to the normal pool water surface elevation above Mendota Dam. The boards-in fish passage facility could be combined with the boards-out fish passage facility (described above) by including multiple entrances and exits on the facility. Otherwise, an independent fish passage facility for boards-in conditions would be constructed. The design of the boards-in fish passage facility is the same as described for the South Canal fish passage facility in Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5.

Main Canal and Helm Ditch Relocations

The Fresno Slough Dam requires the headworks of the Central California Irrigation District's (CCID) Main Canal and Helm Ditch to be reconfigured to divert water from the upstream (south) side of the Fresno Slough Dam. This would allow the District to continue to receive their water supply from the Delta-Mendota Canal and flows from the Fresno Slough without requiring screening of those diversions.

To provide water to the CCID's Main Canal and Helm Ditch, an inlet canal is proposed that would take water from the upstream side of the proposed Fresno Slough Dam, run north adjacent to the west side of the San Joaquin River, and connect to the Main Canal and Helm Ditch just west of their current intakes. This canal would be capable of

conveying the full flow of both the Main Canal and the Helm Ditch combined (1,550 cfs).

The inlet canal would be designed to pass the design flow at anticipated low water levels in the Pool, but it would still provide 2 feet of freeboard at the anticipated high water level. The water elevation in the inlet canal would essentially float with the Mendota Pool. A bridge over the inlet canal would be required to maintain access to Mowry Bridge and the future Fresno Slough Dam. Currently, there is a 20-inch drinking water pipeline for the city of Mendota that crosses the Mowry Bridge. This pipeline would need to be modified so that it crosses the proposed inlet canal on the proposed bridge.

The inlet canal would be concrete lined in locations where erosion is likely to be a concern (i.e., at bends and transitions), and riprap would be placed at the transition from the Pool to the inlet channel.

A concrete control structure would control the water from the inlet canal. It would function to control flows to both the Main Canal and the Helm Ditch. Controlling the flow to the Main Canal would be accomplished with control gates. Upstream of the gates on the eastern wall, a pipeline would deliver water to the relocated head of the Helm Ditch. The concrete pipe, equipped with a canal gate, would serve to control the flow rate as well as shutoff point. It is assumed that existing headworks and telemetry for both the Main Canal and Helm Ditch would be removed from the site, and new telemetry would be installed.

The upstream side of the Main Canal structure would have a cutoff wall to prevent undermining the structure. Downstream of the control structure, the Main Canal would transition both vertically and horizontally into the existing Main Canal alignment and cross-section. The extension of Helm Ditch would be designed to match the cross-section of the existing Helm Ditch downstream.

Removal of River Sediments

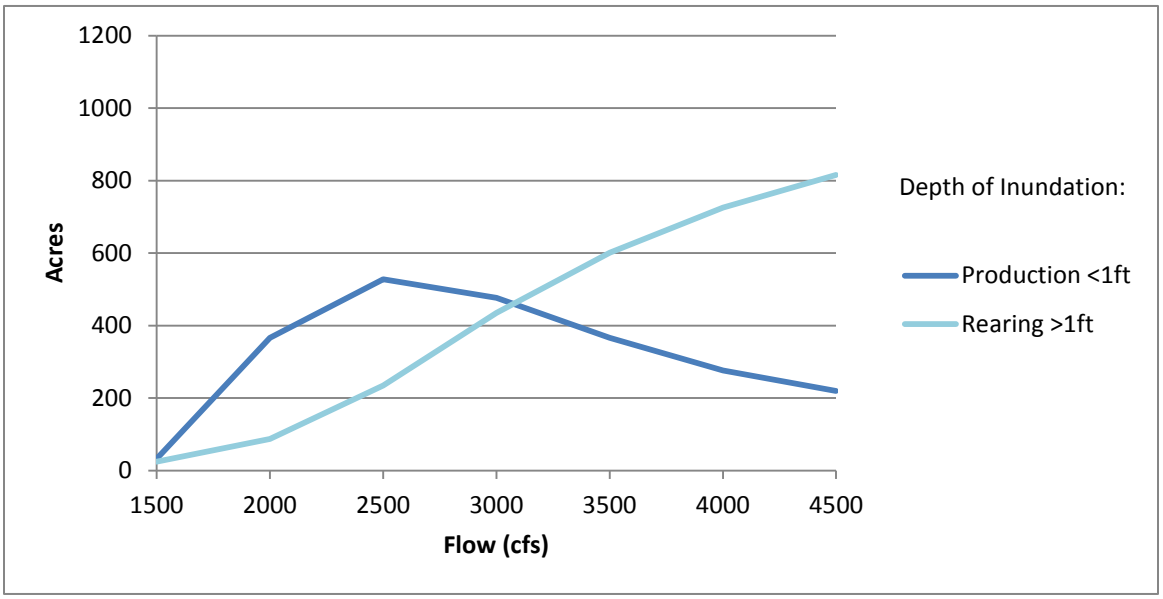
This alternative would make use of the existing river channel from the Chowchilla Bifurcation Structure (approximately RM 216) down to Mendota Dam (approximately RM 204.6) in order to convey Restoration Flows. Since a portion of this river segment is currently impounded by Mendota Dam, sediment has filled in the pre-Mendota Dam channel. This alternative assumes that the sediment would be excavated from portions of the former Pool impoundment area to establish a new equilibrium channel slope. If sediments meet on-site disposal criteria, they may be used to backfill soil borrow areas or to grade low areas on the floodplain.

Fish Habitat and Passage

The purpose of the floodplain would be to provide riparian and floodplain habitat and support the migration and seasonal rearing of salmonids and other native fishes in Reach 2B. The floodplain has an average width of approximately 3,000 feet and an inundated area of approximately 750 acres at 2,500 cfs.

This alternative provides floodplain habitat resulting in approximately 500 acres of shallow water habitat for primary production as well as approximately 250 acres of habitat that supports direct rearing at 2,500 cfs. For this alternative, approximately 65 percent of the floodplain would inundate less than 1 foot deep at 2,500 cfs. This alternative also retains approximately 200 acres of shallow water habitat at flows up to 4,500 cfs.

Figure 2-15 below presents conceptual inundation areas for primary production and rearing habitats as they vary by flow. Inundation acreages may change during the design process.



Source: Tetra Tech 2012

Figure 2-15.
Potential Inundation Acreage by Flow for Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

This alternative includes several facilities that fish may encounter or need to pass to migrate between Reach 3 and Reach 2B (from downstream to upstream):

- An estimated two to four in-channel grade control structures below Mendota Dam.
- The sill of Mendota Dam (when boards are out) or a fish passage facility at Mendota Dam (when boards are in).
- Four fish screen return outlets from the Short Canal fish screen.
- A fish barrier north of the Fresno Slough Dam.
- A fish screen near the upstream end of the Short Canal.
- The San Mateo Avenue crossing.

- Fish screens at Lone Willow Slough, Big and Little Bertha pumps, and other smaller diversions (these screens are discussed in Section 2.2.4).
- A bifurcation control structure at the Chowchilla Bypass with fish passage facility.

Each structure would be designed to perform according to the fish passage design criteria (see Section 2.2.4). In addition, the channel and floodplain incorporate riparian plantings to provide cover, woody material, and velocity variability, while the design footprint allows sufficient space to incorporate channel structure variability during detailed design, all of which may help to reduce stress and predation.

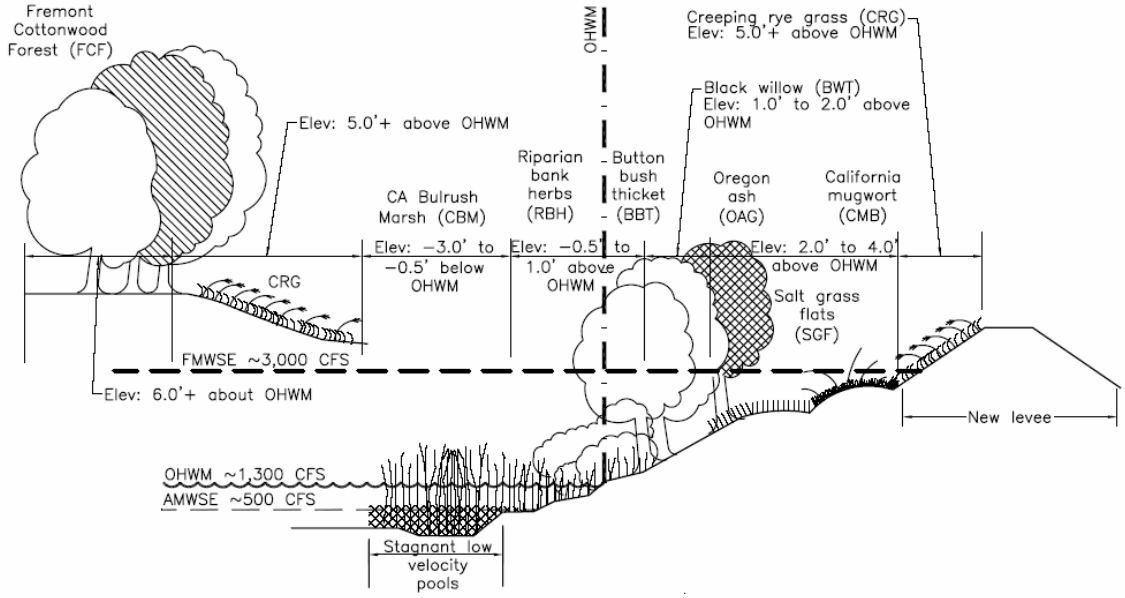
Floodplain and Riparian Habitat

This alternative includes active riparian and floodplain habitat restoration (in contrast to the passive restoration included in Alternative A). It is assumed that wetland communities (obligate, facultative-wet, and facultative species) would develop within the main channel, that a dense riparian scrubland would develop along the main river channel banks, and that bands of other habitat types (wetland, scrub, grassland, and forest) would develop at higher elevations along the channel corridor. The wetland, floodplain, and riparian areas would be planted following construction and then irrigated and managed as necessary during the establishment period. Invasive, non-native species would be removed from the Project area during or following construction, and the Project would include long-term management for invasive species. Phased implementation of active vegetation restoration at strategic locations could occur concurrently with phased implementation of construction and physical infrastructure.

Several native vegetation alliances could be incorporated into the floodplain and habitat planting design (Figure 2-16). The grass-dominated vegetation alliances, which produce the maximum food benefits for salmon, could be more than twice as large as those that would develop with the narrow floodplain alternatives. All of the elevated areas of the meander loops could be maintained or restored to saltgrass flats. The adjacent existing wetland areas within the loops could be preserved or enhanced by additional wetland species plantings and removal of numerous invasive species. The lower lying portions of the reach could be planted with the buttonwillow thicket vegetation alliance. Because of the expanded floodplain and the slowly moving water, the extent of this vegetation alliance could almost quadruple compared to what might develop in the narrow floodplain alternatives.

The extent of black willow thicket and California mugwort brush could also increase over what might develop in the narrow floodplain alternatives. Additional restoration work could focus on the re-establishment of the riparian bank herbs, California bulrush marsh, Oregon ash groves, creeping rye grasslands, and Fremont cottonwood forests. Because of the fast growth and its soft and brittle wood, the cottonwood is considered to be a good source of large woody debris and organic matter within the riverine channel. The riverside levee banks would be planted with native grass species such as those in the creeping rye grassland alliance. Since creeping wild rye (*Leymus triticoides*) is a facultative wetland species that thrives in the upper parts of riparian areas, the extent of

creeping rye grassland could more than double compared to the narrow floodplain alternatives.



Notes: The figure provides an abridged cross-section of the river and floodplain. The upper left-hand portion of the figure shows typical vegetation alliances that would occur on higher ground (above the 3,000 cfs waterline). The left levee would be on the outside, but it is not shown here for brevity purposes. The lower, right-hand portion of the figure shows the range of vegetation alliances that would occur on the levee and on lower ground down to the bottom of the river channel (below the 3,000 cfs waterline).
OHWM – ordinary high water mark; AMWSE = annual mean water surface elevation.

Figure 2-16.
Typical distribution of vegetation alliances along a restored Reach 2B riparian bank section

This alternative would provide potential habitat for greater sandhill crane and Swainson's hawk. The larger floodplains provide increasingly more potential habitat.

Existing Native Vegetation Protection

Existing native vegetation protection would be conducted as described for Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5.

Invasive Species Control

Invasive, non-native species would be removed from the Project area during the installation, plant establishment and maintenance periods. Maintenance and invasive species control would be conducted as described for Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5.

Temporary Irrigation System and Water Supply

Proposed plantings that are wetland species or borderline wetland species would need regular aboveground irrigation (typically April through October) during their establishment period (typically 3 to 5 years depending on rainfall conditions and the

plants' growth rates and vigor). The amount of water needed is estimated to be approximately 2.4 acre feet per year. An extensive temporary aboveground irrigation system, such as aerial spray or drip irrigation, would provide water for the plants several times a week during the hot months of the year. If an aerial spray irrigation system is installed, the irrigation distribution piping would be installed aboveground and anchored to the ground so that it would not be damaged during high flows inundating the floodplain. If an aerial spray system is used, sprinkler heads would likely be installed on braced standpipes so that their irrigation stream would not be blocked or diverted by growing vegetation. The irrigation system would be disassembled and removed at the end of the establishment period.

The Program would pursue options for irrigation water supply, including groundwater wells or water pumped from the river with portable, skid-mounted, diesel- or gas-powered pumps and stored in tanks. Additionally, purchases from willing sellers may be required to withdraw water from the river or other nearby water sources (e.g., Mendota Pool). If water is pumped from the river, the amount of water diverted will be controlled so that river water temperatures do not increase and passage for salmonids is not impaired. The diversion from the river would also be screened to prevent entraining juvenile salmonids.

Maintenance and Monitoring

The key maintenance and monitoring activities include close monitoring of the installed plants for drought stress and overwatering, removal of competitive, invasive, non-native species, replacement of diseased and dead plants, irrigation system maintenance, and removal of trash and debris.

Close monitoring of the installed plants for both drought stress and overwatering would be performed because the proposed plants are native wetland species that can be quickly damaged by lack of irrigation.

For irrigation system maintenance, the system would be used intensively each year on a biweekly to daily basis during the hot part of the growing season. The landscape contractor would be required to regularly check the integrity of the system and make sure that none of the sprinkler heads are clogged or damaged.

Long-Term Management

Long-term management would be conducted as described for Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5.

Water Deliveries

This alternative includes the Short Canal for making up to 2,500 cfs in water deliveries from the San Joaquin River to Mendota Pool. Water deliveries to the Pool would include diversion of Friant Dam releases that are meant to satisfy the Exchange Contract as well as diversion of San Joaquin River flood flows if there is demand in Mendota Pool.

When water deliveries need to occur, the normal pool elevation in Mendota Pool may be higher than the water surface in the river at Fresno Slough Dam. In order for the Short

Canal to be able to deliver water into Mendota Pool, the flash boards of Mendota Dam would be installed, and the water surface in the river would be raised until water could flow from the river south into Mendota Pool via the Short Canal. A fish screen would be included at the Short Canal, and fish passage facilities would be included at Mendota Dam when the boards are in and the diversion is operating.

Construction Considerations

The total construction timeline for this alternative is currently estimated to range approximately from 91 to 133 months (7.5 to 11 years); opportunities to shorten the overall schedule through construction efficiencies will be studied during the detailed design process.

Soil improvements for possible liquefiable soils may be required to protect proposed structures from damage or failure during an earthquake. All proposed structures would be designed to account for potential liquefaction. Soil improvements could include removing and replacing soils with adequate materials, injecting soil-cement slurry, vibrofloatation, dynamic compaction, structural foundation piles (stone or reinforced concrete), and other techniques.[9]

Construction of the Fresno Slough Dam must not interrupt water deliveries. To accomplish this, the construction of the dam would require removable cofferdams in three phases to facilitate the construction without blocking the flow. If flow is present in the slough during the construction period, flow would be diverted around the work area via a temporary diversion pipe or canal and fish passage would be provided.

Stone slope protection (riprap) would be provided on the upstream and downstream slopes of the control structure embankment including some portions of the side slopes of the channel itself to prevent scouring. Riprap would be placed on bedding over geotextile fabric.

Construction of the fish screen and return/bypass fish pipes would take place in the dry using conventional construction methods and must be coordinated with construction of the water delivery canal. The exception to this is the outlet for the fish return pipes, which would require a cofferdam. All fish facility structures and pipes with surfaces exposed to fish require additional attention to surface-smoothness.

For construction of the control structures and fish passage facilities, a minimum flow must be maintained during construction; the amount or range of flows has not yet been identified. For construction at the bifurcation structure, it was assumed that construction would first be done away from the fish passage facility. A sheet pile cofferdam would be provided for the river control structure and/or the canal control structure and the water diverted away from the construction. Additional sheet piling would be provided to divert flows through the new bifurcation structure while the fish passage facility is constructed.

[9] Vibrofloatation uses a vibrating probe that penetrates the soil and causes the grain structure to collapse and increase the density of the soil. Dynamic compaction involves dropping a heavy weight onto soil to compact it.

Summary

Table 2-5 summarizes the levees, relocations, land acquisition, and construction schedule associated with Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal) based on design, field, and evaluation criteria data prepared for the EIS/R.

Table 2-5.
Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)
Levees, Relocations, and Land Acquisition

	Left Levee	Right Levee
Levee Length	7.7 miles	6.9 miles
Average Levee Height	5.6 feet	5.2 feet
Fill Volume	317,500 cubic yards	224,500 cubic yards

Relocations			
Electrical Distribution	48,000 feet	Barn/Shed	1
Gas Transmission	9,000 feet	Facility	1
Water Pipeline	33,000 feet	Groundwater Well	25
Canal	32,500 feet	Lift Pump	10
Culvert	1	Power Pole	166
Diversion	3	Dwelling	2

Land Acquisition and Construction Schedule	
Land Acquisition[1]	2,450 acres
Time to Build[2]	133 months

[1] Total acreage includes areas that are sovereign and public trust lands.

[2] Construction timeline does not include the time that would also be needed to complete the NEPA and CEQA documentation process, obtain permits, appraise and acquire land, and perform pre-construction surveys.

2.2.8 Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal) includes:

- Building levees capable of conveying flows up to 4,500 cfs with 3 feet of freeboard.
- Restoring floodplain habitat an average of approximately 4,200 feet wide to provide benefit to salmonids and other native fishes.
- Constructing a dam capable of containing Mendota Pool within Fresno Slough so that 4,500 cfs of Restoration Flows can be conveyed around the Mendota Pool.
- Constructing the North Canal and structures capable of conveying up to 2,500 cfs from Reach 2B to Mendota Pool.
- Providing upstream and downstream fish passage for adult salmonids and other native fishes, and downstream fish passage for juvenile salmonids, between Reach 2A and Reach 3.

This alternative would build a dam across Fresno Slough, the Fresno Slough Dam, to contain the Mendota Pool, and it would utilize the existing river channel in order to bypass the Mendota Pool. Restoration Flows would enter Reach 2B, flow through the reach, then downstream to Reach 3 over the sill at Mendota Dam. Mendota Pool would be contained south of the Fresno Slough Dam. A canal to convey San Joaquin River water deliveries to Mendota Pool, the North Canal, would be built. The San Joaquin River control structure at the Chowchilla Bifurcation Structure would be removed, and a bifurcation structure would be built at the head of the North Canal to control flood diversions into the Chowchilla Bypass and water delivery diversions into Mendota Pool. Fish passage facilities and a fish screen would be built at the North Canal bifurcation structure to provide passage around the structure and prevent fish being entrained in the diversion. A fish barrier would be built downstream of the Fresno Slough Dam to keep up-migrating fish in Reach 2B. The existing San Mateo Avenue crossing would be removed. These features are described in further detail in the sections below. See Figure 2-17 and Figure 2-18 for a plan view of the alternative's features.

North Canal

The North Canal would deliver up to 2,500 cfs in water deliveries from the San Joaquin River to Mendota Pool. The North Canal could connect to the river at various locations, ideally on a straight section of the river or on the outside of bend. Three optional locations for the junction with the San Joaquin River are shown in Figure 2-17 at approximately RM 209.8, RM 213.4, and RM 214.2. The North Canal would discharge into Fresno Slough approximately 1.8 river miles south of Mendota Dam.

Other aspects of the North Canal are the same as those described for the South Canal in Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5.

Structures

The structures described below would be required to provide the operational flexibility to divert water to the Mendota Pool, provide fish passage, prevent fish entrainment and straying, and provide controlled elevation drop between Reach 2B and Reach 3.

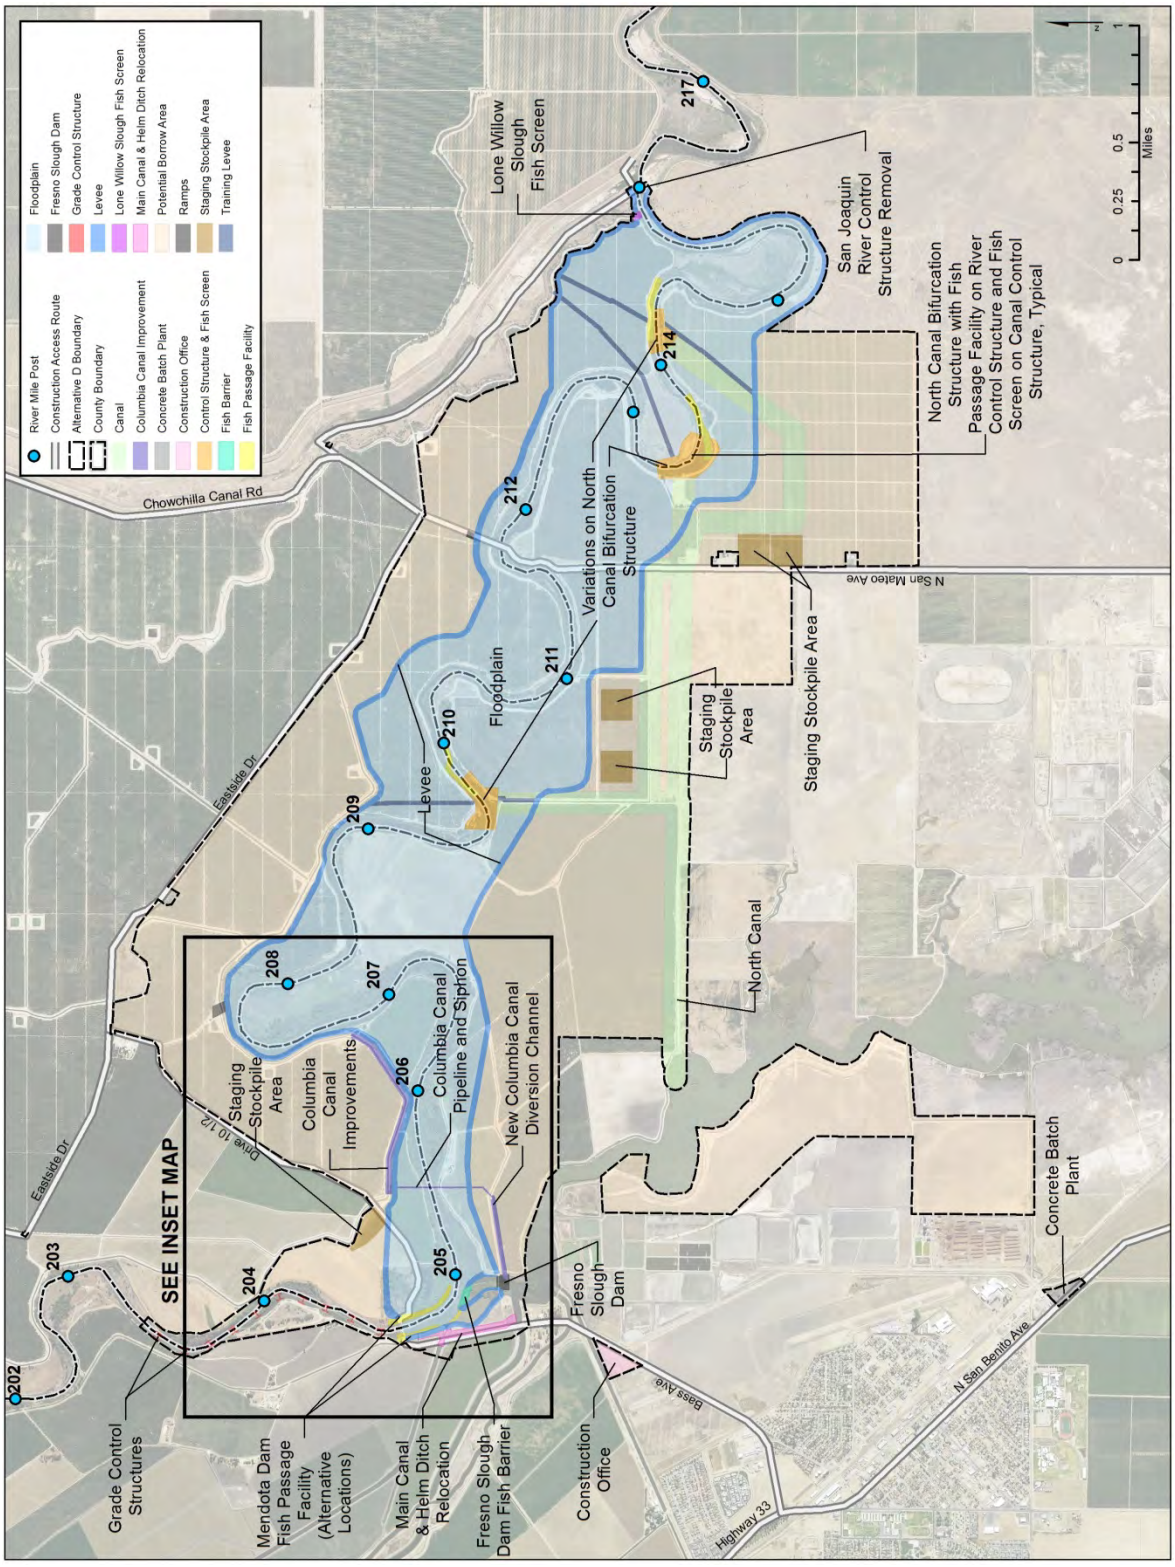


Figure 2-17.
Plan View of Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

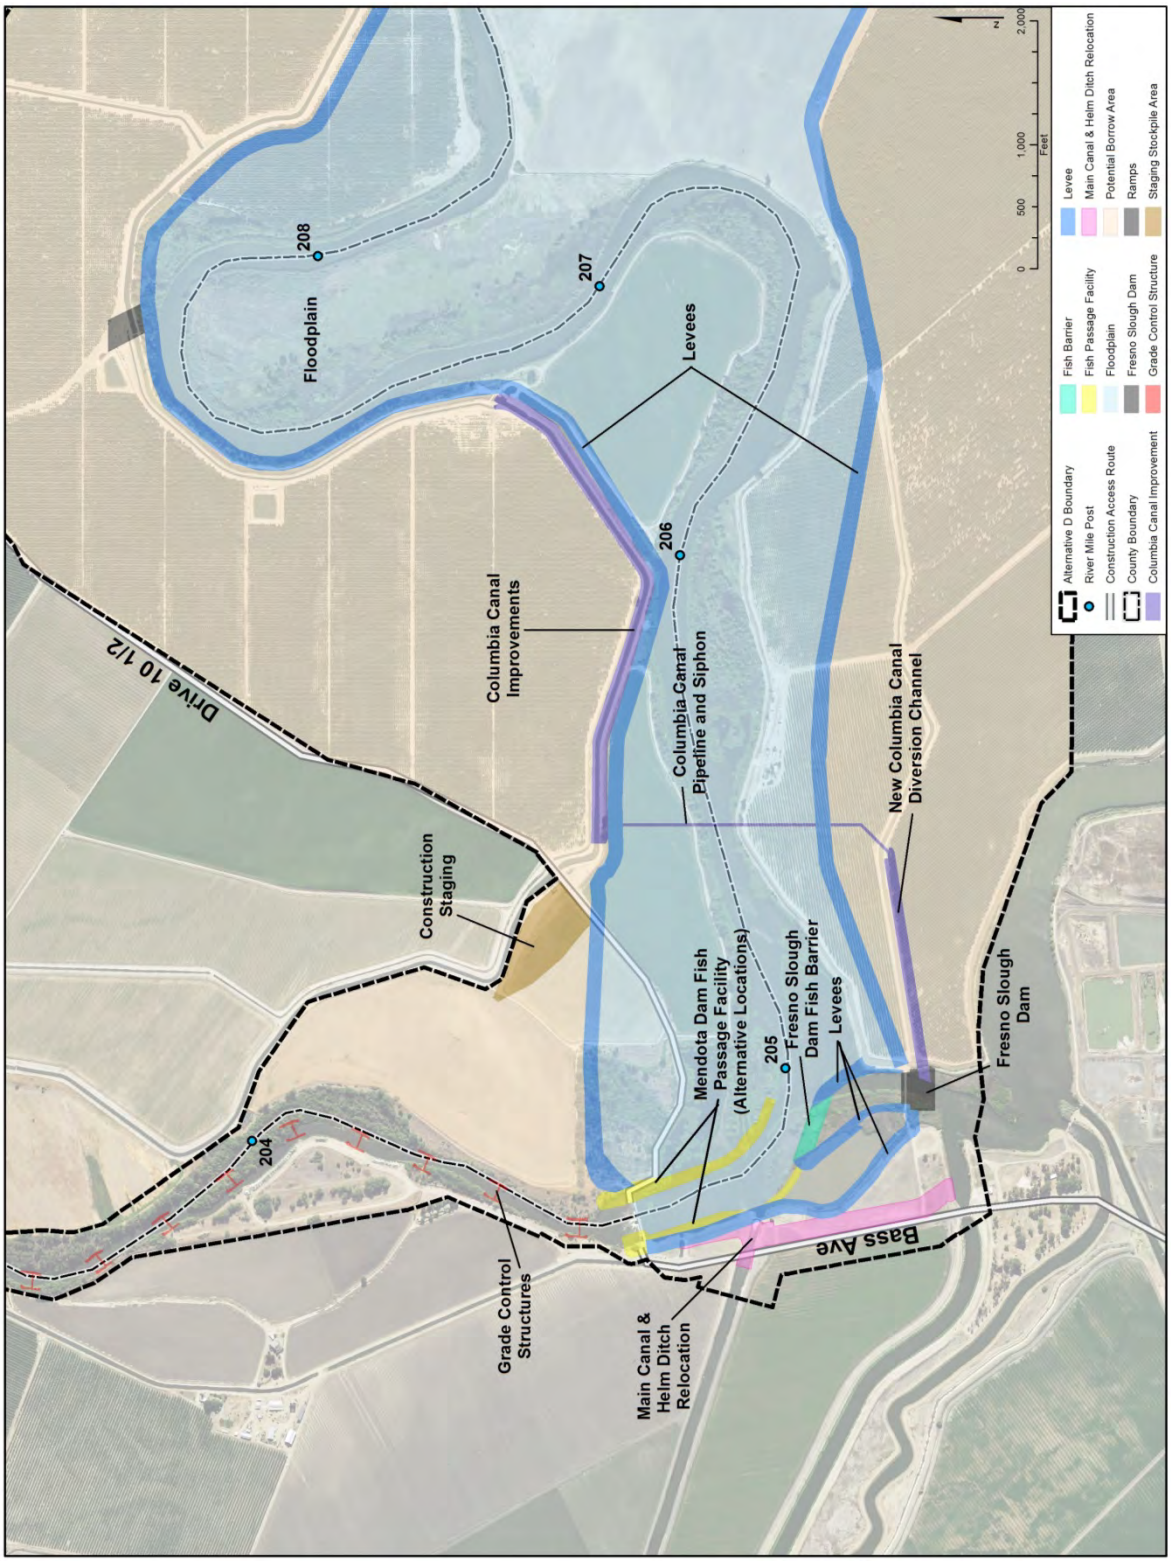

Figure 2-18.
Inset Map of Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

San Joaquin River Control Structure at the Chowchilla Bifurcation Structure Removal

The Chowchilla Bifurcation Structure consists of two control structures: one at the head of the Chowchilla Bypass and one across the San Joaquin River at RM 216. With the inclusion of a bifurcation structure at the head of the North Canal, a new control structure would be built across the San Joaquin River at the head of the canal. The new control structure would alleviate the need for the San Joaquin River control structure at the Chowchilla Bifurcation Structure because all diversions into the Chowchilla Bypass could be controlled from the new control structure at the head of the North Canal. As part of this alternative, the San Joaquin River control structure at the Chowchilla Bifurcation Structure would be demolished.

North Canal Bifurcation Structure

A bifurcation structure would be constructed at the upstream end of the North Canal. The bifurcation structure consists of two control structures: one across the path of Restoration Flows (San Joaquin River) and one across the path of water deliveries to Mendota Pool (North Canal). The North Canal bifurcation structure is the same as described for Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5.

North Canal Fish Passage Facility

The North Canal bifurcation structure would include a fish passage facility on the side of the control structure across the Restoration Flow path. The fish passage facility would be necessary to provide passage during water deliveries and for Restoration Flows where passage conditions through the control structure may not be ideal. The design of the fish passage facility is the same as that presented for the South Canal fish passage facility in Section 2.2.5.

North Canal Fish Screen

A fish screen would be included at the head of the North Canal where water deliveries would be diverted from the river. The fish screen would be necessary to keep or return out-migrating juvenile salmon to the San Joaquin River (the path of Restoration Flows) during water deliveries. The North Canal fish screen is the same as described for the South Canal in Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5.

San Mateo Avenue Crossing Removal

The San Mateo Avenue crossing is an existing river crossing located within a public right-of-way in Madera County and on private land in Fresno County at approximately RM 211.8. The crossing transitions from public right-of-way to private land at the center of the river. The crossing consists of a low flow or dip crossing with a single culvert. As part of this alternative, the culvert and road embankments would be demolished, and no river crossing would be provided at this location.

Fresno Slough Dam

The Fresno Slough Dam is the same as that described in Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal) in Section 2.2.7.

Fresno Slough Dam Fish Barrier

The Fresno Slough Dam fish barrier is the same as that described in Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal) in Section 2.2.7.

Mendota Dam Fish Passage Facilities

The Mendota Dam fish passage facilities are the same as described for the boards-out condition in Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal) in Section 2.2.7.

Main Canal and Helm Ditch Relocations

The Main Canal and Helm Ditch relocations are the same as described in Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal) in Section 2.2.7.

Removal of River Sediments

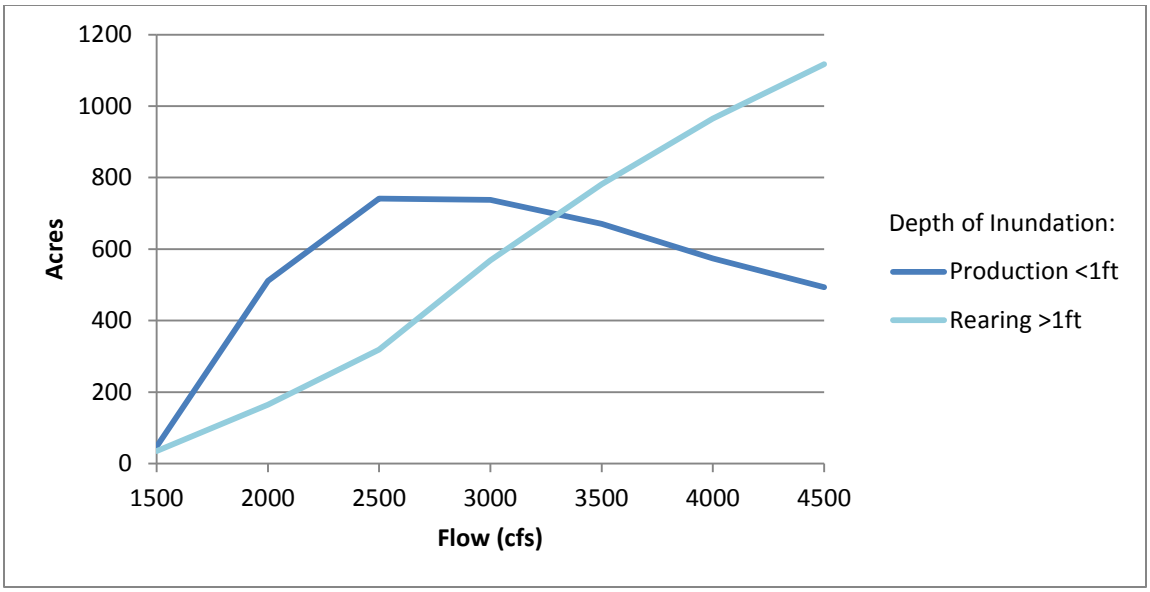
The removal of river sediment is the same as described in Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal) in Section 2.2.7.

Fish Habitat and Passage

The purpose of the floodplain would be to provide riparian and floodplain habitat and support the migration and seasonal rearing of salmonids and other native fishes in Reach 2B. The floodplain has an average width of approximately 4,200 feet and an inundated area of approximately 1,050 acres at 2,500 cfs.

This alternative provides floodplain habitat resulting in approximately 750 acres of shallow water habitat for primary production as well as approximately 300 acres of habitat that supports direct rearing at 2,500 cfs. Approximately 70 percent of the floodplain in this alternative would inundate less than 1 foot deep at 2,500 cfs. This alternative also retains approximately 500 acres of shallow water habitat at flows up to 4,500 cfs.

Figure 2-19 below presents conceptual inundation areas for primary production and rearing habitats as they vary by flow. Inundation acreages may change during the design process.



Source: Tetra Tech 2012

Figure 2-19.
Potential Inundation Acreage by Flow for Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

This alternative includes several facilities that fish may encounter or need to pass to migrate between Reach 3 and Reach 2B (from downstream to upstream):

- An estimated two to four in-channel grade control structures below Mendota Dam.
- The sill of Mendota Dam.
- A fish barrier north of the Fresno Slough Dam.
- Four fish screen return outlets from the North Canal fish screen.
- A bifurcation control structure at the North Canal with fish passage facility.
- A fish screen near the upstream end of the North Canal.
- Fish screens at Lone Willow Slough, Big and Little Bertha pumps, and other smaller diversions (these screens are discussed in Section 2.2.4).

Each structure represents a potential stressor for adult salmon and potential predation site for juvenile salmon. However, each structure would be designed to perform according to the fish passage design criteria (see Section 2.2.4). In addition, the channel and floodplain incorporate riparian plantings to provide cover, woody material, and velocity variability, while the design footprint allows sufficient space to incorporate channel structure variability during detailed design, all of which may help to reduce stress and predation.

Floodplain and Riparian Habitat

Floodplain and riparian habitat restoration actions are similar to those described for Alternative A (Compact Bypass with Narrow Floodplain and South Canal) in Section 2.2.5 would be included in this alternative.

Water Deliveries

This alternative includes the North Canal for making up to 2,500 cfs in water deliveries from the San Joaquin River to Mendota Pool. Water deliveries to the Pool would include diversion of Friant Dam releases that are meant to satisfy the Exchange Contract as well as diversion of San Joaquin River flood flows if there is demand in Mendota Pool.

When water deliveries occur, the gates at the North Canal bifurcation structure would be manipulated to control flows into the downstream river channel and allow flows into the North Canal. To create sufficient hydraulic head to allow water to flow into the canal, operation of the gates would include backwatering a small portion of the San Joaquin River upstream of the North Canal bifurcation structure. The extent of the backwater is anticipated to be small and dependent on the design slope of the canal. Up-migrating fish passage along Reach 2B would occur through the North Canal fish passage facility during water deliveries. The North Canal fish screen would capture out-migrating fish entering the diversion and return them to the river. Some flow in the downstream river channel would be maintained during water delivery operations during fish migration periods.

Construction Considerations

The total construction timeline for this alternative is currently estimated to range approximately from 97 to 158 months (8 to 13 years); opportunities to shorten the overall schedule through construction efficiencies will be studied during the detailed design process. The construction considerations are the same as described for Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal) in Section 2.2.7.

Summary

Table 2-6 summarizes the levees, relocations, land acquisition, and construction schedule associated with Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal) based on design, field, and evaluation criteria data prepared for the EIS/R.

Table 2-6.
Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)
Levees, Relocations, and Land Acquisition

	Left Levee	Right Levee
Levee Length	7.2 miles	6.6 miles
Average Levee Height	5.2 feet	4.2 feet
Fill Volume	272,000 cubic yards	188,250 cubic yards

Relocations			
Electrical Distribution	68,000 feet	Barn/Shed	1
Gas Transmission	11,500 feet	Facility	1
Water Pipeline	50,000 feet	Groundwater Well	32
Canal	56,000 feet	Lift Pump	10
Culvert	1	Power Pole	239
Diversion	3	Dwelling	2

Land Acquisition and Construction Schedule	
Land Acquisition[1]	3,300 acres
Time to Build[2]	158 months

[1] Total acreage includes areas that are sovereign and public trust lands.

[2] Construction timeline does not include the time that would also be needed to complete the NEPA and CEQA documentation process, obtain permits, appraise and acquire land, and perform pre-construction surveys.

2.2.9 Alternatives Comparison Tables

The table below (Table 2-7) combines the summary tables from Sections 2.2.5, 2.2.6, 2.2.7, and 2.2.8 in order to allow easy cross-comparison of the Action Alternatives.

Table 2-7.
Levees, Relocations, and Land Acquisition

	Alternative A	Alternative B	Alternative C	Alternative D
Levees				
Left Levee Length	8.7 miles	8.1 miles	7.7 miles	7.2 miles
Left Average Levee Height	5.8 feet	5.6 feet	5.6 feet	5.2 feet
Left Fill Volume	345,200 cubic yards	328,600 cubic yards	317,500 cubic yards	272,000 cubic yards
Right Levee Length	7.1 miles	6.8 miles	6.9 miles	6.6 miles
Right Average Levee Height	5.4 feet	4.7 feet	5.2 feet	4.2 feet
Right Fill Volume	269,700 cubic yards	226,900 cubic yards	224,500 cubic yards	188,250 cubic yards

Table 2-7.
Levees, Relocations, and Land Acquisition

Land Acquisition and Construction Schedule				
Land Acquisition[1]	2,700 acres	2,900 acres	2,450 acres	3,300 acres
Time to Build[2]	132 months	157 months	133 months	158 months

[1] Total acreage includes areas that are sovereign and public trust lands.

[2] Construction timeline does not include the time that would also be needed to complete the NEPA and CEQA documentation process, obtain permits, appraise and acquire land, and perform pre-construction surveys.

2.2.10 Environmental Commitments

Environmental commitments are measures or practices adopted by a project proponent to reduce or avoid adverse effects that could otherwise result from project construction or operations. The following section describes additional environmental commitments that would be implemented with the Action Alternatives to avoid potentially adverse environmental consequences. These commitments are consistent with those commitments provided in the PEIS/R.

Conservation Strategy

As part of Program implementation, a comprehensive strategy for the conservation of listed and sensitive species and habitats has been prepared, and will be implemented in coordination with USFWS, NMFS, and DFW. The strategy's purpose is to serve as a tool built into the project description to minimize and avoid potential impacts to sensitive species and habitats. This Conservation Strategy guides development and implementation of specific conservation measures for project-level actions. The Conservation Strategy includes conservation goals and measures for species and communities (such as avoidance, minimization, monitoring, and management measures) consistent with adopted recovery plans, as described below. If avoidance and minimization measures are

impractical or infeasible, then adaptive management measures would be pursued and developed in coordination with the appropriate regulatory agency.

To achieve the Restoration Goal, a number of actions that are proposed to be implemented may substantially alter not only the aquatic ecosystem of the San Joaquin River, but also the river's riparian and wetland ecosystems, and some adjacent upland ecosystems. Riparian, wetland, and upland ecosystems of the Central Valley, such as those along the San Joaquin River, provide habitat for a large number of species, including several Federally-listed and State-listed species. Therefore, the Action Alternatives include the Program's Conservation Strategy, which would be implemented in a manner that is consistent with adopted conservation plans for sensitive species, and for wetland and riparian ecosystems of the Restoration Area.

The Conservation Strategy consists of management actions that would result in a net benefit for riparian and wetland habitats in the Project area, to avoid reducing the long-term viability of sensitive species, and to be consistent with adopted conservation plans. The goals of the strategy are described below:

- **Conserve riparian vegetation and waters of the United States, including wetlands** – Project implementation would likely result in a net increase in the acreage of riparian and wetland vegetation in the Project area. However, several Project actions may disturb or eliminate riparian vegetation or waters of the United States (including wetlands). If impacts to waters of the United States (including wetlands), navigable waters, or the Federal levee system cannot be avoided, a Corps Section 404, Section 408, and/or Section 10 permit and Central Valley Regional Water Quality Control Board (RWQCB) Section 401 water quality certification would be obtained. Increased acreage of wetlands resulting from Interim and Restoration flows may be considered a means of replacing, restoring, or enhancing wetlands. However, the acreage, location, and methods of replacing, restoring, or enhancing wetlands would be determined during these permitting processes. The SJRRP has been actively working with resource agencies to further develop the Program's *Riparian Habitat Monitoring, Mitigation, and Management Plan*.
- **Control and manage invasive species** – Because of their adverse effects on aquatic and riparian ecosystems, the spread of invasive plant species as a result of Project would be controlled and managed. For each invasive plant species with known infestations, thresholds for management responses and specific management responses would be established and implemented (including species-specific control methods).
- **Conserve special-status species** – Populations of special-status species would benefit from restoring and sustaining riparian and wetland habitat, and controlling invasive species, as described previously. However, during construction-related activities, a variety of special-status species of upland, wetland, and riparian habitats could experience adverse effects. Therefore, the Conservation Strategy includes measures to prevent or reduce impacts that could result from loss of habitat within the Project footprint or from impacts on adjacent habitat or species.

In addition, this strategy includes coordination with appropriate regulatory agencies to provide mitigation or compensation, consistent with applicable conservation plans, to avoid or minimize effects when actions would result in a net loss of habitat or other substantial adverse effects, if the implementation of avoidance and minimization measures is infeasible or impractical.

These measures address all potentially affected Federally-listed and/or State-listed species, and all other species identified by USFWS, NMFS, or DFW as candidates, sensitive, or special-status in local or regional plans, policies, or regulations. For individual actions under each of the Action Alternatives, the applicable, feasible measures would guide development of action-specific conservation strategies. Table 2-8 presents the elements of the Program's Conservation Strategy as applicable to the Project. The measures presented here are the same as those presented in the PEIS/R (SJRRP 2011a, pages 2-55 to 2-79).

Table 2-8.
Conservation Measures for Biological Resources That May Be Affected by Project Actions

Conservation Measure and Identifier	Applicable Habitat and/or Species, and Conservation Measure Description	Regulatory Agency
VELB		
VELB-1. Avoid and Minimize Effects to Species	If elderberry shrubs and valley elderberry longhorn beetle are anticipated within the project area, within 1 year before the commencement of ground-disturbing activities, a qualified biologist shall identify any elderberry shrubs in the project footprint. Qualified biologist(s) will survey potentially affected shrubs for valley elderberry longhorn beetle exit holes in stems greater than 1 inch in diameter. If elderberry shrubs are found on or adjacent to the construction project site, if feasible, a 100-foot-wide avoidance buffer – measured from the dripline of the plant – will be established around elderberry shrubs with stems greater than 1 inch in diameter at ground level and will be clearly identified in the field by staking, flagging, or fencing. No activities will occur within the buffer areas and worker awareness training and biological monitoring will be conducted to ensure that avoidance measures are being implemented.	USFWS
VELB -2. Compensate for Temporary or Permanent Loss of Habitat	The project proponent will consult with USFWS to determine appropriate compensation ratios. Compensatory mitigation measures will be consistent with the *Conservation Guidelines for Valley Elderberry Longhorn Beetle* (USFWS 1999a), or current guidance. Compensatory mitigation for adverse effects may include transplanting elderberry shrubs during the dormant season (November 1 to February 15), if feasible, to an area protected in perpetuity, as well as required additional elderberry and associated native plantings and approved by USFWS. If off-site compensation includes dedication of conservation easements, purchase of mitigation credits, or other off-site conservation measures, the details of these measures will be included in the mitigation plan and must occur with full endowments for management in perpetuity. The plan will include information on responsible parties for long-term management, holders of conservations easements, long-term management requirements, and other details, as appropriate, for the	USFWS

Table 2-8.
Conservation Measures for Biological Resources That May Be Affected by Project Actions

Conservation Measure and Identifier	Applicable Habitat and/or Species, and Conservation Measure Description	Regulatory Agency
	preservation of long-term viable populations.	
BNLL	**Blunt-Nosed Leopard Lizard**	
BNLL-1. Avoid and Minimize Effects to Species	Three areas have been identified as having potential blunt-nosed leopard lizard habitat based on aerial maps. These areas include approximately 2,460 acres along the southwest side of the San Joaquin River in Reach 2, approximately 490 acres in a portion of the Eastside Bypass and adjacent lands near Reach 4A of the San Joaquin River, and approximately 2,938 acres encompassing the northern side of the Mariposa Bypass and parcels north of the Mariposa Bypass and west of the Eastside Bypass. Within 1 year before the commencement of the proposed project, focused site visits and habitat assessment will be conducted on these lands. Based on focused assessment, and discussions with the USFWS and DFW, protocol-level surveys may be conducted. If blunt-nosed leopard lizard are detected within or adjacent to the project site, measures that will avoid direct take of this species will be developed in cooperation with USFWS and DFW and implemented before ground disturbing activities.	USFWS DFW
BNLL-2. Compensate for Temporary or Permanent Loss of Habitat or Species	Compensation for impacts to the species, if needed, will be determined in coordination with USFWS and DFW, as appropriate.	USFWS DFW
PLANTS	**Other Special-Status Plants**	
PLANTS-1. Avoid and Minimize Effects to Special-Status Plants	Within 1 year before the commencement of ground-disturbing activities, habitat assessment surveys for the special-status plants listed in Table 1 of Appendix L of the PEIS/R, "Biological Resources – Vegetation and Wildlife," that are applicable to Reach 2B will be conducted by a qualified botanist, in accordance with the most recent USFWS and DFW guidelines and at the appropriate time of year when the target species would be in flower or otherwise clearly identifiable. Locations of special-status plant populations will be clearly identified in the field by staking, flagging, or fencing a minimum 100-foot-wide buffer around them before the commencement of activities that may cause disturbance. No activity shall occur within the buffer area, and worker awareness training and biological monitoring will be conducted to ensure that avoidance measures are being implemented. Some special-status plant species are annual plants, meaning that a plant completes its entire life cycle in one growing season. Other special-status plant species are perennial plants that return year after year until they reach full maturity. Because of the differences in plant life histories, all general conservation measures will be developed on a case-by-case basis and will include strategies that are species- and site-specific to avoid impacts to special-status plants.	USFWS DFW
GGS	**Giant Garter Snake**	
GGS-1. Avoid and Minimize Loss of Habitat	If giant garter snake habitat is anticipated to be present within the project area, preconstruction surveys will be completed by a qualified biologist approved by USFWS and DFW within a 24-hour period before	Reclamation USFWS DFW

Table 2-8.
Conservation Measures for Biological Resources That May Be Affected by Project Actions

Conservation Measure and Identifier	Applicable Habitat and/or Species, and Conservation Measure Description	Regulatory Agency
for Giant Garter Snake	any ground disturbance of potential giant garter snake habitat. If construction activities stop on the project site for a period of 2 weeks or more, a new giant garter snake survey will be completed no more than 24 hours before the restart of construction activities. Avoidance of suitable giant garter snake habitat, as defined by USFWS (USFWS 1993) and DFW, will occur by demarcating and maintaining a 300-foot-wide buffer around these areas. For projects within potential giant garter snake habitat, all activity involving disturbance of potential giant garter snake habitat will be restricted to the period between May 1 and October 1, the active season for giant garter snakes. The construction site shall be re-inspected if a lapse in construction activity of 2 weeks or greater has occurred. Clearing will be confined to the minimal area necessary to facilitate construction activities. Giant garter snake habitat within or adjacent to the project will be flagged, staked, or fenced and designated as an Environmentally Sensitive Area. No activity shall occur within this area, and USFWS-approved worker awareness training and biological monitoring will be conducted to ensure that avoidance measures are being implemented. Construction activities shall be minimized within 200 feet of the banks of giant garter snake habitat. Movement of heavy equipment will be confined to existing roadways to minimize habitat disturbance. Vegetation shall be hand-cleared in areas where giant garter snakes are suspected to occur. Exclusionary fencing with one-way exit funnels shall be installed at least 1 month before activities to allow the species to passively leave the area and to prevent reentry into work zones, per USFWS and/or DFW guidance. If a giant garter snake is found during construction activities, USFWS, DFW, and the project's biological monitor will immediately be notified. The biological monitor, or his/her assignee, will stop construction in the vicinity of the find and allow the snake to leave on its own. The monitor will remain in the area for the remainder of the work day to ensure the snake is not harmed. Escape routes for giant garter snake should be determined in advance of construction and snakes will be allowed to leave on their own. If a giant garter snake does not leave on its own within 1 working day, USFWS and DFW will be consulted. All construction-related holes shall be covered to prevent entrapment of individuals. Where applicable, construction areas shall be dewatered 2 weeks before the start of activities to allow giant garter snakes and their prey to move out of the area before any disturbance.	
GGS-2. Compensate for Temporary or Permanent Loss of Habitat	Temporarily affected giant garter snake aquatic habitat will be restored in accordance with criteria listed in the USFWS Mitigation Criteria for Restoration and/or Replacement of Giant Garter Snake Habitat (Appendix A to *Programmatic Formal Consultation for U.S. Army Corps of Engineers 404 Permitted Projects with Relatively Small Effects on the Giant Garter Snake Within Butte, Colusa, Glenn, Fresno, Merced, Sacramento, San Joaquin, Solano, Stanislaus, Sutter, and Yolo Counties, California* (USFWS 1997)), or the most current criteria from USFWS or DFW. Permanent loss of giant garter snake habitat will be compensated at a	USFWS DFW

Table 2-8.
Conservation Measures for Biological Resources That May Be Affected by Project Actions

Conservation Measure and Identifier	Applicable Habitat and/or Species, and Conservation Measure Description	Regulatory Agency
	ratio and in a manner consulted on with USFWS and DFW. Compensation may include preservation and enhancement of existing populations, restoration or creation of suitable habitat, or purchase of credits at a regulatory-agency-approved mitigation bank in sufficient quantity to compensate for the effect. Credit purchases, land preservation, or land enhancement to minimize effects to giant garter snakes should occur geographically close to the impact area. If off-site compensation is chosen, it shall include dedication of conservation easements, purchase of mitigation credits, or other off-site conservation measures, and the details of these measures will be included in the mitigation plan and must occur with full endowments for management in perpetuity. The plan will include information on responsible parties for long-term management, holders of conservations easements, long-term management requirements, and other details, as appropriate, for the preservation of long-term viable populations.	
WPT	**Western Pond Turtle**	
WPT-1. Avoid and Minimize Loss of Individuals	A qualified biologist will conduct surveys in aquatic habitats to be dewatered and/or filled during project construction. Surveys will be conducted immediately after dewatering and before fill of aquatic habitat suitable for western pond turtles. If western pond turtles are found, the biologist will capture them and move them to nearby USFWS- and/or DFW-approved areas of suitable habitat that will not be disturbed by project construction.	DFW
EAGLE	**Bald Eagle and Golden Eagle**	
EAGLE-1. Avoid and Minimize Effects to Bald and Golden Eagles (as Defined in the Bald and Golden Eagle Protection Act)	Surveys for bald and golden eagle nests will be conducted within 2 miles of any proposed project within areas supporting suitable nesting habitat and important eagle roost sites and foraging areas. These surveys will be conducted in accordance with the USFWS *Protocol for Evaluating Bald Eagle Habitat and Populations in California* and DFW *Bald Eagle Breeding Survey Instructions* or current guidance (*USFWS Draft Project Design Criteria and Guidance for Bald and Golden Eagles*). If an active eagle's nest is found, project disturbance will not occur within ½-mile of the active nest site during the breeding season (typically December 30 to July 1) or any project disturbance if it is shown to disturb the nesting birds. A no-disturbance buffer will be established around the nest site for construction activities in consultation with USFWS and DFW, and will depend on ecological factors, including topography, surrounding vegetation, nest height, and distance to foraging habitat, as well as the type and magnitude of disturbance. Project activity will not occur within the ½-mile-buffer areas, and worker awareness training and biological monitoring will be conducted to ensure that avoidance measures are being implemented.	USFWS DFW
SWH	**Swainson's Hawk**	
SWH-1. Avoid and Minimize Impacts to Swainson's	Preconstruction surveys for active Swainson's hawk nests will be conducted in and around all potential nest trees within ½-mile of project-related disturbance (including construction-related traffic). These surveys will be conducted in accordance with *the Recommended*	DFW

Table 2-8.
Conservation Measures for Biological Resources That May Be Affected by Project Actions

Conservation Measure and Identifier	Applicable Habitat and/or Species, and Conservation Measure Description	Regulatory Agency
Hawk	*Timing and Methodology for Swainson's Hawk Nesting Surveys in California's Central Valley* (Swainson's Hawk Technical Advisory Committee 2000) or current guidance. If known or active nests are identified through preconstruction surveys or other means, a ½-mile no-disturbance buffer shall be established around all active nest sites if construction cannot be limited to occur outside the nesting season (February 15 through September 15). Worker awareness training and biological monitoring will be conducted to ensure that avoidance measures are being implemented.	
SWH-2. Compensate for Loss of Nest Trees and Foraging Habitat	If foraging habitat for Swainson's hawk is removed in association with project implementation, foraging habitat compensation will occur in coordination with DFW. Foraging habitat mitigation may consist of planting and establishing alfalfa, row crops, pasture, or fallow fields. If potential nesting trees are to be removed during construction activities, removal will take place outside of Swainson's hawk nesting season, and the project proponent will develop a plan to replace known Swainson's hawk nest trees with a number of equivalent native trees that were previously determined to be impacts through consultation with DFW. Compensation shall include dedication of conservation easements, purchase of mitigation credits, or other off-site conservation measures, and the details of these measures will be included in the mitigation plan and must occur with full endowments for management in perpetuity. The plan will include information on responsible parties for long-term management, holders of conservations easements, long-term management requirements, and other details, as appropriate, for the preservation of long-term viable populations.	DFW
RAPTOR	**Other Nesting Raptors**	
RAPTOR-1. Avoid and Minimize Loss of Individual Raptors	Construction activity, including vegetation removal, will only occur outside the typical breeding season for raptors (September 16 to December 31), if raptors are determined to be present. Preconstruction surveys will be conducted by a qualified biologist in areas of suitable habitat to identify active nests in the project footprint. If active nests are located in the project footprint, a no-disturbance buffer will be established until a qualified biologist determines that the nest is no longer active. The size of the buffer shall be established by a qualified biologist in coordination with DFW based on the sensitivity of the resource, the type of disturbance activity, and nesting stage. No activity shall occur within the buffer area, and worker awareness training and biological monitoring will be conducted to ensure that avoidance measures are being implemented.	DFW
RAPTOR-2. Compensate for Loss of Nest Trees	Native trees removed during project activities will be replaced with an appropriate number of native trees, in coordination with DFW.	DFW
RNB	**Riparian Nesting Birds: Least Bell's Vireo**	
RNB-1. Avoid Effects to Species	If least Bell's vireo is anticipated within a project area, a qualified biologist shall make an initial site visit to determine if suitable habitat for the species may exist within the project footprint. Where suitable habitat may be present, reconnaissance-level surveys	USFWS DFW

Table 2-8.
Conservation Measures for Biological Resources That May Be Affected by Project Actions

Conservation Measure and Identifier	Applicable Habitat and/or Species, and Conservation Measure Description	Regulatory Agency
	would be conducted by biologists adhering to guidance offered in *Least Bell's Vireo Survey Guidelines*, USFWS, January 19, 2001.	
RNB-2. Avoid, Minimize, and Compensate for Effects to Species	If least Bell's vireo is detected or suspected to be present in the project footprint, information would be collected according to the guidelines stated in RNB-1. USFWS and DFW would be contacted to determine the approach for avoidance, minimization, or compensation.	USFWS DFW
MBTA	**Other Birds Protected by the Migratory Bird Treaty Act**	
MBTA-1. Avoid and Minimize Effects to Species	Native nesting birds will be avoided by not conducting project activity, including vegetation removal, during the typical breeding season (February 1 to September 1), if species covered under the Migratory Bird Treaty Act and Fish and Game Code sections 3503, 3503.5, and 3513 are determined to be present. An Avian Protection Plan shall be established in coordination with USFWS and DFW. Any overhead utility companies within the project area, whose lines, poles, or towers may be moved in association with the project, will also be consulted as part of the Avian Protection Plan.	USFWS DFW
BRO	**Burrowing Owl**	
BRO-1. Avoid Loss of Species	Preconstruction surveys for burrowing owls will be conducted in areas supporting potentially suitable habitat and within 30 days before the start of construction activities. If ground-disturbing activities are delayed or suspended for more than 30 days after the preconstruction survey, the site should be resurveyed. These surveys and mitigation will be conducted in accordance with the *Burrowing Owl Survey Protocol and Mitigation Guidelines* (The California Burrowing Owl Consortium 1993), or current guidance. Occupied burrows shall not be disturbed during the breeding season (February 1 through August 31). A minimum 160-foot-wide buffer shall be placed around occupied burrows during the nonbreeding season (September 1 through January 31), and a 250-foot-wide buffer shall be placed around occupied burrows during the breeding season. Ground-disturbing activities shall not occur within the designated buffers.	DFW
BRO-2. Minimize Impacts to Species	If a DFW-approved biologist can verify through noninvasive methods that owls have not begun egg-laying and incubation, or that juveniles from occupied burrows are foraging independently and are capable of independent survival, a plan shall be coordinated with DFW to offset burrow habitat and foraging areas on the project site if burrows and foraging areas are taken by SJRRP actions. Mitigation measures will be consistent with the *Staff Report on Burrowing Owl Mitigation* (DFW 2012), or current guidance. If destruction of occupied burrows occurs, existing unsuitable burrows should be enhanced (enlarged or cleared of debris) or new burrows created. This should be done in consultation with DFW. Passive owl relocation techniques must be implemented. Owls should be excluded from burrows in the immediate impact zone within a 160-foot-wide buffer zone by installing one-way doors in burrow entrances. These doors shall be in place at least 48 hours before excavation to insure the owls have departed. The project area shall be monitored daily for 1 week to confirm owl	DFW

Table 2-8.
Conservation Measures for Biological Resources That May Be Affected by Project Actions

Conservation Measure and Identifier	Applicable Habitat and/or Species, and Conservation Measure Description	Regulatory Agency
	departure from burrows before any ground-disturbing activities. Where possible, burrows should be excavated using hand tools and refilled to prevent reoccupation. Sections of flexible plastic pipe should be inserted into the tunnels during excavation to maintain an escape route for any animals inside the burrow.	
BAT	**Special-Status Bats**	
BAT-1. Avoid and Minimize Loss of Species	If suitable roosting habitat for special-status bats will be affected by project construction (e.g., removal of buildings, modification of bridges), surveys for roosting bats on the project site will be conducted by a qualified biologist. The type of survey will depend on the condition of the potential roosting habitat and may include visual surveys or use of acoustic detectors. Visual surveys may consist of a daytime pedestrian survey for evidence of bat use (e.g., guano) and/or an evening emergence survey for the presence or absence of bats and will include trees within ¼-mile of project construction activities. The type of survey will depend on the condition of the potential roosting habitat. If no bat roosts are found, then no further study is required. If evidence of bat use is observed, the number and species of bats using the roost will be determined. Bat detectors may be used to supplement survey efforts. If roosts are determined to be present and must be removed, the bats will be excluded from the roosting site before the facility is removed. A mitigation program addressing compensation, exclusion methods, and roost removal procedures will be developed in consultation with DFW before implementation. Exclusion methods may include use of one-way doors at roost entrances (bats may leave, but not reenter), or sealing roost entrances when a site can be confirmed to contain no bats. Exclusion efforts may be restricted during periods of sensitive activity (e.g., during hibernation or while females in maternity colonies are nursing young).	DFW
BAT-2. Compensate for Loss of Habitat	The loss of each roost will be replaced, in consultation with DFW, and may include construction and installation of bat boxes suitable to the bat species and colony size excluded from the original roosting site. Roost replacement will be implemented before bats are excluded from the original roost sites. Once the replacement roosts are constructed and it is confirmed that bats are not present in the original roost sites, the structure may be removed.	DFW
FKR	**Fresno Kangaroo Rat**	
FKR-1. Avoid and Minimize Effects to Species	Preconstruction surveys will be conducted by a qualified biologist per USFWS and DFW survey methodology to determine if potential burrows for Fresno kangaroo rat are present in the project footprint. Surveys will be conducted within 30 days before ground-disturbing activities. The biologist will conduct burrow searches by systematically walking transects, which shall be adjusted based on vegetation height and topography, and in coordination with USFWS and DFW. Transects shall be used to identify the presence of kangaroo rat burrows. When burrows are found within 100 feet of the Project footprint, focused live trapping surveys shall be conducted by a qualified and permitted biologist, following a methodology approved in advance by USFWS and	USFWS DFW

Table 2-8.
Conservation Measures for Biological Resources That May Be Affected by Project Actions

Conservation Measure and Identifier	Applicable Habitat and/or Species, and Conservation Measure Description	Regulatory Agency
	DFW. Additional conservation measures may be developed pending the results of surveys, and in consultation with USFWS and DFW. Construction activities shall be conducted when they are least likely to affect the species (i.e., after the normal breeding season of December through September (Ahlborn 1999)). This timing shall be coordinated with USFWS and DFW.	
FKR-3. Compensate for Temporary or Permanent Loss of Habitat or Species	Compensation for impacts to the species, if needed, will be determined in coordination with DFW and USFWS, as appropriate.	USFWS DFW
SJKF	**San Joaquin Kit Fox**	
SJKF-1. Avoid and Minimize Effects to Species	A qualified biologist will conduct preconstruction surveys no less than 14 days and no more than 30 days before the commencement of activities to identify potential dens more than 5 inches in diameter. The project proponent shall implement USFWS' (1999b) *Standardized Recommendations for Protection of San Joaquin Kit Fox Prior to or During Ground Disturbance.* The project proponent will notify USFWS and DFW in writing of the results of the preconstruction survey within 30 days after these activities are completed. If dens are located within the proposed work area, and cannot be avoided during construction activities, a USFWS-approved biologist will determine if the dens are occupied. If occupied dens are present within the proposed work, their disturbance and destruction shall be avoided. Exclusion zones will be implemented following the latest USFWS procedures (currently USFWS 1999b). The project proponent will notify USFWS and DFW immediately if a natal or pupping den is found in the survey area. The project proponent will present the results of preactivity den searches within 5 days after these activities are completed and before the start of construction activities in the area. Construction activities shall be conducted when they are least likely to affect the species (i.e., after the normal breeding season of December–April (Ahlborn 2000)). This timing shall be coordinated with USFWS and DFW.	USFWS DFW
PL	**Pacific Lamprey**	
PL-1. Avoid and Minimize Effects to Species	A qualified biologist will conduct preconstruction surveys as outlined in Attachment A of USFWS' *Best Management Practices to Minimize Adverse Effects to Pacific Lamprey* (*Entosphenus tridentatus*) (2010). Work in documented areas of Pacific lamprey presence will be timed to avoid in-channel work during typical lamprey spawning (March 1 to July 1). If temporary dewatering in documented areas of lamprey presence is required for instream channel work, salvage methods shall be	USFWS

Table 2-8.
Conservation Measures for Biological Resources That May Be Affected by Project Actions

Conservation Measure and Identifier	Applicable Habitat and/or Species, and Conservation Measure Description	Regulatory Agency
	implemented to capture and move ammocoetes to a safe area, in consultation with USFWS.	
RHSNC	**Riparian Habitat and Other Sensitive Natural Communities**	
RHSNC-1. Avoid and Minimize Loss of Riparian Habitat and Other Sensitive Natural Communities	Biological surveys will be conducted to identify, map, and quantify riparian and other sensitive habitats in potential construction areas. Construction activities will be avoided in areas containing sensitive natural communities, as appropriate.	DFW
RHSNC-2. Compensate for Loss of Riparian Habitat and Other Sensitive Natural Communities	The Riparian Habitat Mitigation and Monitoring Plan for the SJRRP will be developed and implemented in coordination with DFW. Credits for increased acreage or improved ecological function or riparian and wetland habitats resulting from the implementation of SJRRP actions will be applied as compensatory mitigation before additional compensatory measures are required. If losses of other sensitive natural communities (e.g., recognized as sensitive by CNDDB, but not protected under other regulations or policies) would not be offset by the benefits of the SJRRP, then additional compensation will be provided through creating, restoring, or preserving in perpetuity in-kind communities at a sufficient ratio for no net loss of habitat function or acreage. The appropriate ratio will be determined in consultation with USFWS or DFW, depending on agency jurisdiction.	DFW
WUS	**Waters of the United States/Waters of the State**	
WUS-1. Identify and Quantify Wetlands and Other Waters of the United States	Before SJRRP actions that may affect waters of the United States or waters of the State, Reclamation will map the distribution of wetlands (including vernal pools and other seasonal wetlands) in the Eastside and Mariposa bypasses. The project proponent will determine, based on the mapped distribution of these wetlands and hydraulic modeling and field observation, the acreage of effects, if any, on waters of the United States. If it is determined that vernal pools or other seasonal wetlands will be affected by the SJRRP, the project proponent will conduct a delineation of waters of the United States, and submit the delineation to the Corps for verification. The delineation will be conducted according to methods established in the Corps *Wetlands Delineation Manual* and *Arid West Supplement* (Corps Environmental Laboratory 1987, 2008). Construction and modification of road crossings, control structures, fish barriers, fish passages, and other structures will be designed to minimize effects on waters of the United States and waters of the State, and will employ BMPs to avoid indirect effects on water quality.	Corps
WUS-2. Obtain Permits and Compensate for Any Loss of Wetlands and Other Waters of	The project proponent, in coordination with the Corps, will determine the acreage of effects on waters of the United States and waters of the State that will result from implementation of the SJRRP. The project proponent will adhere to a “no net loss” basis for the acreage of wetlands and other waters of the United States and waters of the State that will be removed and/or degraded. Wetland habitat will	Corps

Conservation Measures for Biological Resources That May Be Affected by Project Actions

Conservation Measure and Identifier	Applicable Habitat and/or Species, and Conservation Measure Description	Regulatory Agency
the United States/Waters of the State	be restored, enhanced, and/or replaced at acreages and locations and by methods agreed on by the Corps and the Central Valley RWQCB, and DFW, as appropriate, depending on agency jurisdiction. The project proponent will obtain Section 404 and Section 401 permits and comply with all permit terms. The acreage, location, and methods for compensation will be determined during the Section 401 and Section 404 permitting processes. The compensation will be consistent with recommendations in the Fish and Wildlife Coordination Act Report (Appendix F of the PEIS/R).	
INV	**Invasive Plants**	
INV-1. Implement the Invasive Vegetation Monitoring and Management Plan	Reclamation will implement the Invasive Vegetation Monitoring and Management Plan for the SJRRP (Appendix L of the PEIS/R), which includes measures to monitor, control, and where possible eradicate, invasive plant infestations during flow releases and construction activities. The implementation of the Invasive Vegetation Monitoring and Management Plan (Appendix L of the PEIS/R) will include monitoring procedures, thresholds for management responses, success criteria, and adaptive management measures for controlling invasive plant species. The control of invasive weeds and other recommended actions in the Invasive Vegetation Monitoring and Management Plan (Appendix L of the PEIS/R) will be consistent with recommendations in the Fish and Wildlife Coordination Act Report (Appendix F of the PEIS/R).	Reclamation
CP	**Conservation Plans**	
CP-1. Remain Consistent with Approved Conservation Plans	Facility siting and construction activities will be conducted in a manner consistent with the goals and strategies of adopted habitat conservation plans, natural community conservation plans, or other approved local, regional, or State habitat conservation plans to the extent feasible. Coordination shall occur with USFWS and/or DFW, as appropriate.	USFWS DFW
CP-2. Compensate Effects Consistent with Approved Conservation Plans	The project proponent shall compensate effects consistent with applicable conservation plans and implement all applicable measures required by the plans.	USFWS DFW
GS	**Southern Distinct Population Segment of North American Green Sturgeon**	
GS-1. Avoid and Minimize Loss of Habitat And Individuals	The SJRRP will be operated in such a way that actions affecting green sturgeon habitat shall be done in accordance with existing operating criteria of the CVP and SWP, and prevailing and relevant laws, regulations, BOs, and court orders in place when the action(s) are performed.	NMFS
CVS	**Central Valley Steelhead**	
CVS-1. Avoid Loss of Habitat and Risk of	Impacts to habitat conditions (i.e., changes in flows potentially resulting in decreased flows in the tributaries, increases in temperature, increases in pollutant concentration, change in recirculation/recapture	NMFS

Table 2-8.
Conservation Measures for Biological Resources That May Be Affected by Project Actions

Conservation Measure and Identifier	Applicable Habitat and/or Species, and Conservation Measure Description	Regulatory Agency
Take of Species	rates and methods, decrease in floodplain connectivity, removal of riparian vegetation, decreased in quality rearing habitat, etc.) must be analyzed in consultation with NMFS. The Hills Ferry Barrier will be operated and maintained to exclude Central Valley steelhead from the Restoration Area during construction activities and until suitable habitat conditions are restored. Maintenance of conservation measures will be conducted to the extent necessary to ensure that the overall long-term habitat effects of the project are positive. Before implementation of site-specific actions, the action agency shall conduct an education program for all agency and contracted employees relative to the Federally listed species that may be encountered within the study area of the action, and required practices for their avoidance and protection. A NMFS-appointed representative shall be identified to employees and contractors to ensure that questions regarding avoidance and protection measures are addressed in a timely manner. Disturbance of riparian vegetation will be avoided to the greatest extent practicable. A spill prevention plan will be prepared describing measures to be taken to minimize the risk of fluids or other materials used during construction (e.g., oils, transmission and hydraulic fluids, cement, fuel) from entering the San Joaquin River or contaminating riparian areas adjacent to the river itself. In addition to a spill prevention plan, a cleanup protocol will be developed before construction begins and shall be implemented in case of a spill. Stockpiling of materials, including portable equipment, vehicles and supplies, such as chemicals, shall be restricted to the designated construction staging areas, exclusive of any riparian and wetland areas. A qualified biological monitor will be present during all construction activities, including clearing, grubbing, pruning, and trimming of vegetation at each job site during construction initiation, midway through construction, and at the close of construction, to monitor implementation of conservation measures and water quality. The San Joaquin River channel shall be designed to decrease or eliminate predator holding habitat, in coordination with NMFS.	
CVS-2. Minimize Loss of Habitat and Risk of Take of Species	In-channel construction activities that could affect designated critical habitat for Central Valley steelhead will be limited to the low-flow period between June 1 and October 1 to minimize potential for adversely affecting Federally listed anadromous salmonids during their emigration period. In-channel construction activities that could affect designated critical habitat for Central Valley steelhead will be limited to daylight hours during weekdays, leaving a nighttime and weekend period of passage for Federally listed fish species. Construction BMPs for off-channel staging, and storage of equipment and vehicles, will be implemented to minimize the risk of contaminating the waters of the San Joaquin River by spilled materials. BMPs will also include minimization of erosion and stormwater runoff, as appropriate. Riparian vegetation removed or damaged will be replaced at a ratio, coordinated with NMFS, within the immediate area of the disturbance to	NMFS

	maintain habitat quality. If individuals of listed species are observed present within a project area, NMFS must be notified. NMFS personnel shall have access to construction sites during construction, and following completion, to evaluate species presence and condition and/or habitat conditions. If bank stabilization activities should be necessary, then such stabilization shall be constructed to minimize predator habitat, minimize erosion potential, and contain material suitable for supporting riparian vegetation.	
SRCS	**Central Valley Spring-Run Chinook Salmon**	
SRCS-1. Avoid and Minimize Loss of Habitat and Individuals	The SJRRP will be operated in such a way that actions in the vicinity of spring-run Chinook salmon habitat shall be done in accordance with existing operating criteria of the CVP and SWP, and prevailing and relevant laws, regulations, BOs, and court orders in place at the time the actions are performed. SJRRP actions shall be performed in accordance with the Experimental Population 4(d) rule, as it is developed, and where applicable.	NMFS DFW
EFH	**Essential Fish Habitat (Pacific Salmonids)**	
EFH-1. Avoid Loss of Habitat and Risk of Take of Species	Impacts to habitat conditions (e.g., changes in flows potentially resulting in decreased flows in the tributaries, increases in temperature, increases in pollutant concentration, change in recirculation/recapture rates and methods, decrease in floodplain connectivity, removal of riparian vegetation, decreased in quality rearing habitat) must be analyzed in consultation with NMFS. The Hills Ferry Barrier will be operated and maintained to exclude Pacific salmonids from the Restoration Area during construction activities, and until suitable habitat conditions are restored. Under historical operations, the Hills Ferry Barrier is operated September through mid-December. The period of operation under this measure may vary from historical operations. Maintenance of conservation measures will be conducted to the extent necessary to ensure that the overall long-term habitat effects of the project are positive. Before implementation of site-specific actions, the action agency shall conduct an education program for all agency and contracted employees relative to the Federally listed species that may be encountered within the study area of the action, and required practices for their avoidance and protection. A NMFS-appointed representative shall be identified to employees and contractors to ensure that questions regarding avoidance and protection measures are addressed in a timely manner. Disturbance of riparian vegetation will be avoided to the greatest extent practicable. A spill prevention plan will be prepared describing measures to be taken to minimize the risk of fluids or other materials used during construction (e.g., oils, transmission and hydraulic fluids, cement, fuel) from entering the San Joaquin River or contaminating riparian areas adjacent to the river itself. In addition to a spill prevention plan, a cleanup protocol will be developed before construction begins and shall	NMFS

Minimize Flood Risk from Restoration Flows

The Program's strategy for minimizing flood risk is to limit the maximum downstream extent and rate of Restoration Flows for the given reach to then-existing channel capacities. This strategy is incorporated by reference from the PEIS/R (SJRRP 2011a, pages 2-22 through 2-28) and summarized here. These Program-wide commitments are documented in the PEIS/R Record of Decision (ROD). No new Project-level actions to minimize flood risk from Restoration Flows are being proposed.

Throughout Settlement implementation, the maximum downstream extent and rate of Restoration Flows to be released through a reach will be maintained at or below then-existing channel capacities. As channel or structure modifications are completed, maximum Restoration Flow releases will be correspondingly increased in accordance with then-existing channel capacities and with the release schedule. Consistent with the San Joaquin River Restoration Settlement Act, Interim Flows (2009-2014) were reduced, as needed, to address material seepage impacts, as identified through the monitoring program (see the Program's *Physical Monitoring and Management Plan* and *Seepage Management Plan* (PEIS/R Appendices D.1 and D.2, SJRRP 2011a)). If release of water from Friant Dam is required for flood control purposes, concurrent Restoration Flows will be reduced by an amount equivalent to the required flood control release. If flood control releases from Friant exceed the concurrent scheduled Restoration Flows, no additional releases above those required for flood control will be made for SJRRP purposes.

Then-existing channel capacities within the Restoration Area correspond to flows that would not significantly increase flood risk from Interim and Restoration flows in the Restoration Area (see the *Channel Capacity Report* (SJRRP 2015)). The action to release Restoration Flows includes measures that would achieve the following objectives: (1) commit Reclamation to implementing actions that would meet performance standards that minimize increases in flood risk as a result of Restoration Flows, (2) limit the release and conveyance of Restoration Flows to those flows that would remain in-channel until adequate data are available to apply the performance standards and until the performance standards are satisfied, and (3) enable the Settlement to be implemented in coordination with other ongoing and future actions outside of the Settlement that could address channel capacity issues identified in the Settlement or through the SJRRP or other programs. Implementation of measures that achieve these objectives will allow for the safe release and conveyance of Restoration Flows throughout the duration of Settlement implementation.

Reclamation will continue to implement the following three integrated measures that collectively minimize increases in flood risk as a result of Restoration Flows during Settlement implementation:

- **Establish a Channel Capacity Advisory Group and Determine and Update Estimates of Then-Existing Channel Capacities as Needed –** The establishment and administration of a Channel Capacity Advisory Group to provide independent review of estimated then-existing channel capacities, monitoring results, and

management actions to address vegetation and sediment transport within the system as identified by Reclamation.

- **Maintain Restoration Flows at or Below Estimates of Then-Existing Channel Capacities –** The process for limiting Restoration Flows to reduce the risk of levee failure due to underseepage, through-seepage, and associated levee stability issues to less-than-significant levels.
- **Closely Monitor Erosion and Perform Maintenance and/or Reduce Restoration Flows as Necessary to Avoid Erosion-Related Impacts –** The commitment by Reclamation to implement erosion monitoring and management, including monitoring potential erosion sites, reducing Restoration Flows as necessary, and reporting ongoing results of monitoring and management actions to the Channel Capacity Advisory Group.

Only limited data are currently available on San Joaquin River channel capacities and levee conditions. The levee design criteria developed by the Corps and presented in *Design and Construction of Levees Engineering and Design Manual* (Manual No. 1110-2-1913) (Corps 2000a), *Slope Stability* (Manual No. 1110-2-1902) (Corps 2003), and *Design Guidance for Levee Underseepage* (Engineering Technical Letter No. 1110-2-569) (Corps 2005) will be applied throughout the Restoration Area to identify the Restoration Flows that would not cause the levee slope stability Factor of Safety to be reduced below 1.4, or the underseepage Factor of Safety to be reduced below the value corresponding to an exit gradient at the toe of the levee of 0.5. The levee slope stability Factor of Safety is defined as the ratio of available shear strength of the top stratum of the levee slope to the necessary shear strength to keep the slope stable (Corps 2003), and minimum levee slope stability factors of safety are given by the Corps levee criteria shown in Table 2-9. The application of the levee slope stability Factor of Safety of 1.4 is required for federally authorized flood control projects. Through-seepage is calculated as part of the slope stability analysis and does not have a separate Factor of Safety. The underseepage Factor of Safety is defined as a ratio of the critical hydraulic gradient to the actual exit gradient of seepage on the levee. Corps design guidance recommends that the allowable underseepage factor of safety for use in evaluations and/or design of seepage control measures should correspond to an exit gradient at the toe of the levee of 0.5 (in general, this would provide a Factor of Safety of 1.6), but states that deviation from recommended design guidance is acceptable when based and documented on sound engineering judgment and experience (Corps 2005).

Until adequate data are available to determine the Factor of Safety, Reclamation would limit the release of Interim and Restoration flows to those which would remain in-channel. In-channel flows are flows that maintain a water surface elevation at or below the elevation of the landside levee toe (i.e., the base of the levee). When sufficient data are available to determine the Factor of Safety, Reclamation will limit Restoration Flows to levels that would correspond to a Factor of Safety of 1.4 or higher and an underseepage Factor of Safety corresponding to an exit gradient at the toe of the levee of 0.5 or lower at all times. Observation of levee erosion, seepage, boils, impaired emergency levee access, or other indications of increased flood risk identified through ongoing monitoring at potential erosion sites would indicate that the minimum Factor of

Safety is not met and would trigger immediate reductions in Restoration Flows at the site. Such observations would supersede channel capacity estimates, and Restoration Flows will be reduced in areas where these conditions occur.

Table 2-9.
Minimum Factors of Safety - Levee Slope Stability

Type of Slope	Applicable Stability Conditions and Required Factors of Safety			
	End-of-Construction	Long-Term (Steady Seepage)	Rapid Drawdown[a]	Earthquake[b]
New Levees	1.3	1.4	1.0 to 1.2	(see below)
Existing Levees	--	1.4[c]	1.0 to 1.2	(see below)
Other Embankments and Dikes[d]	1.3[e,f]	1.4[c,f]	1.0 to 1.2[f]	(see below)

Source: U.S. Army Corps of Engineers 2000a. Design and Construction of Levees Engineering and Design Manual. Manual No. 1110-2-1913. April. Table 6-1b, page 6-5.

Notes:

[a] Sudden drawdown analyses. F. S. = 1.0 applies to pool levels prior to drawdown for conditions where these water levels are unlikely to persist for long periods preceding drawdown. F. S. = 1.2 applies to pool level, likely to persist for long periods prior to drawdown.

[b] See ER 1110-2-1806 for guidance. An EM for seismic stability analysis is under preparation.

[c] For existing slopes where either sliding or large deformation have occurred previously and back analyses have been performed to establish design shear strengths lower factors of safety may be used. In such cases probabilistic analyses may be useful in supporting the use of lower factors of safety for design.

[d] Includes slopes which are part of cofferdams, retention dikes, stockpiles, navigation channels, breakwater, river banks, and excavation slopes.

[e] Temporary excavated slopes are sometimes designed for only short-term stability with the knowledge that long-term stability is not adequate. In such cases higher factors of safety may be required for end-of-construction to ensure stability during the time the excavation is to remain open. Special care is required in design of temporary slopes, which do not have adequate stability for the long-term (steady seepage) condition.

[f] Lower factors of safety may be appropriate when the consequences of failure in terms of safety, environmental damage and economic losses are small.

Other Environmental Commitments

The Project proponents will implement the following measures to avoid potentially adverse environmental consequences. Many of these measures are consistent with those specified in the PEIS/R ROD.

Air Quality

- The Project proponents will comply with San Joaquin Valley Air Pollution Control District (SJVAPCD) Regulation VIII. Control measures will be implemented to reduce emissions of particulate matter (predominantly dust/dirt) generated by Project activities, including construction and demolition activities, road construction, bulk materials storage, paved and unpaved roads, carryout and track out, and landfill operations. Control measures include phasing work to reduce the amount of surface area disturbed at any one time, applying water to the construction site to limit visual dust emissions, limiting the speed vehicles travel on unpaved access/haul roads, storing and handling bulk materials in such a manner that minimizes visual dust emissions, minimizing carryout and trackout of

soils from unpaved surfaces to paved surfaces, and preparing and implementing a Dust Control Plan.

- The Project proponents will comply with SJVAPCD Rule 9510, "Indirect Source Review," which requires on-site emission reducing design elements and/or the payment of fees that would be used to fund off-site emissions reduction projects. Construction emissions would be reduced onsite by using add-on controls, cleaner fuels, and/or newer lower-emissions equipment, as described in Chapter 4, "Air Quality."
- The Project proponents will implement Mitigation Measures AQ-1A, AQ-1B, AQ-1C, AQ-2, AQ-3A, and AQ-3B, as described in Chapter 4.0, "Air Quality." Implementation of these measures will reduce criteria exhaust emissions from construction equipment, reduce criteria exhaust emissions from material hauling vehicles, offset Project construction emissions through a SJVAPCD voluntary emission reduction agreement, reduce or offset Project emissions, reduce diesel particulate matter emissions from construction equipment, and reduce diesel particulate matter emissions from material hauling vehicles.

Cultural Resources

- The Project proponents will implement Mitigation Measures CUL-1A, CUL-1B, CUL-1C, CUL-1D, CUL-1E, and CUL-2, as described in Chapter 9.0, "Cultural Resources." With implementation of these measures, the Project proponents will comply with Section 106 of the NHPA or equivalent, conduct subsurface testing and/or archaeological monitoring in proximity to identified sites or areas of sensitivity, halt work in the event of an archaeological discovery, plan an intentional site burial preservation in place (where applicable), avoid soil borrowing in the vicinity of known archaeological resources, and follow the Secretary of the Interior's standards for the treatment of historic properties.

Geology and Soils

- Site-specific geotechnical exploration, testing, and analysis will be conducted prior to final design to allow for the characterization of site soils and appropriate design of proposed structures with respect to potentially corrosive soils or subsidence conditions.
- Project proponents will prepare and implement a stormwater pollution prevention plan that complies with applicable Federal regulations concerning construction activities. (This measure is the same as GRW-1A and SQW-1.)
- Excavation of borrow materials will be done in accordance with Reclamation design standards, and comply with provisions of the Clean Water Act Section 402 and the National Pollutant Discharge Elimination System Construction General Permit.

Hydrology – Groundwater

- The Project proponents will implement Mitigation Measures GRW-1A and GRW-1B, as described in Chapter 13.0, "Hydrology – Groundwater." With implementation of these measures, the Project proponents will prepare and implement a stormwater pollution prevention plan and a construction groundwater management plan.

Hydrology – Surface Water Resources and Water Quality

- The Project proponents will implement Mitigation Measures SWQ-1 and SWQ-3, as described in Chapter 14.0, "Hydrology – Surface Water Resources and Water Quality." With implementation of these measures, the Project proponents will develop and implement a stormwater pollution prevention plan and minimize the use of pesticide and herbicide contaminated soil.

Land Use Planning and Agricultural Resources

- The Project proponents will implement Mitigation Measures LU-1, LU-2, LU-3, and LU-5, as described in Chapter 16.0, "Land Use Planning and Agricultural Resources." With implementation of these measures, the Project proponents will preserve agricultural productivity of designated farmland to the extent possible, and notify County planning agencies of general plan and zoning ordinance inconsistencies.

Noise and Vibration

- The Project proponents will implement Mitigation Measures NOI-1, NOI-2, and NOI-3, as described in Chapter 17.0, "Noise and Vibration." Implementation of these measures will reduce temporary and short-term noise levels from construction-related equipment near sensitive receptors, minimize vibration-related effects, and reduce temporary noise levels from construction-related traffic increases near sensitive receptors.

Paleontological Resources

- The Project proponents will implement Mitigation Measures PAL-1, as described in Chapter 18.0, "Paleontological Resources." With implementation of these measures, the Project proponents will stop work if paleontological resources are encountered during earthmoving activities and implement a recovery plan.

Public Health and Hazardous Materials

- The Project proponents will comply with the California Environmental Protection Agency's (Cal/EPA's) Unified Program.
- The Project proponents will comply with Federal, State, and local hazardous materials regulations, as applicable, monitored by the State (e.g., California

Occupational Safety and Health Administration [Cal/OSHA], Department of Toxic Substances Control, California Highway Patrol) and/or local jurisdictions.

- Project proponents will adopt reasonable wildland fire safety strategies and have the firefighting equipment required by Cal/OSHA during all phases of construction.
- The Project proponents will implement Mitigation Measures HAZ-2A, HAZ-2B, HAZ-2C, HAZ-2D, HAZ-2E, HAZ-3, HAZ-4, HAZ-5, and HAZ-6, as described in Chapter 19.0, "Public Health and Hazardous Materials." With implementation of these measures, the Project proponents will follow general hazardous materials guidelines, properly dispose of hazardous building components, properly dispose of pesticides, properly manage discolored or odiferous soils, properly remove underground storage tanks, minimize disturbance to known hazardous material sites, minimize use of pesticide and herbicide contaminated soil, minimize exposure to potential West Nile Virus carrying vectors, minimize exposure to potential Hantavirus vectors, minimize exposure to Valley Fever, and minimize the disturbance of idle or abandoned wells.

Recreation

- The Project proponents will implement Mitigation Measures REC-1 and REC-2, as described in Chapter 20.0, "Recreation." With implementation of these measures, the Project proponents will minimize construction effects on recreation uses and establish boat portage facilities around Project facilities.

Transportation and Traffic

- The Project proponents will comply with Department of Motor Vehicles codes by requiring contractors and employees to be properly licensed and endorsed when operating commercial vehicles.
- The Project proponents will comply with California Vehicle Code section 35551 by enforcing compliance with weight restrictions on vehicles traveling on freeways and highways and by requiring heavy haulers to obtain permits, if required, prior to delivery of any heavy haul load.
- The Project proponents will comply with California Vehicle Code section 35780 by requiring heavy haulers to obtain a Single-Trip Transportation Permit prior to delivery of any oversized load.
- The Project proponents will coordinate with the California Department of Transportation (Caltrans) for relocation of any structures or fixtures necessary to telegraph, telephone, or electric power lines or of any ditches, pipes, drains, sewers, or underground structures located in the public rights-of-way.
- As required by the PEIS/R ROD, Project proponents will prepare and implement a traffic management plan that identifies the number of truck trips, time of day for arrival and departure of trucks, limits on number of truck trips, and traffic circulation control measures. Control measures typically include advertising planned lane closures, warning signage, a flag person to direct traffic flows when

needed, and methods for maintaining continued access by emergency vehicles. During project construction, access to existing land uses will be maintained at all times, with detours used as necessary during road closures. The traffic management plan will be submitted to the appropriate county public works, fire, police, and sheriff departments for comments.

- The Project proponents will implement Mitigation Measures TRA-4A and TRA-4B, as described in Chapter 22.0, "Transportation and Traffic." With implementation of these measures, the Project proponents will provide a temporary roadway and crossing at San Mateo Avenue and use construction sequencing to provide continuous emergency access at Drive 10 ½, where applicable.

Utilities and Service Systems

- As required by the PEIS/R ROD to minimize and avoid disruption of subsurface utilities from ground disturbing activities, Project proponents will (1) confirm the location of existing underground utilities, (2) coordinate with the owners of transmission lines and pipelines, (3) design restoration actions to avoid affecting underground facilities, if feasible, and (4) coordinate with the utility owner to shut off and relocate the utilities, as necessary.
- The location of public utilities will be confirmed and appropriate notifications will be made by contacting utility providers (e.g., power and communication utility service, and irrigation district service) who operate, maintain or own utilities in the Project area.
- Construction contractors will request an underground service alert from Underground Service Alert North in advance of earthmoving activities to locate and avoid underground utilities.
- Solid waste removed from the Project area will be disposed of in a permitted landfill. The operator of the recycling/disposal location will be notified and Project proponents will obtain approval for the type and amount of solid waste that will be generated.

Visual Resources

- The Project proponents will implement Mitigation Measures VIS-1 and VIS-6, as described in Chapter 24.0, "Visual Resources." With implementation of these measures, the Project proponents will minimize visual disruption from construction activities and conform to lighting standards, where applicable.

Permitting

Reclamation will obtain all necessary permits, as required by law. Implementation of the Project may require the permits and approvals described in Table 2-10. In general, Federal and State actions (permit issuance) will require a signed ROD (NEPA) and findings, EIR certification, and Notice of Determination (NOD) documents (CEQA). Additional information on permit acquisition procedures, submittal package

requirements, critical issues, timing, and permit fees is discussed in the Project's Regulatory Compliance TM (SJRRP 2011b).

SWRCB = State Water Resources Control Board
USFWS = U.S. Fish and Wildlife Service

2.3 Alternatives Considered and Eliminated from Further Consideration

Formulation of a range of Project alternatives for inclusion in this EIS/R began with a review of Settlement provisions for achieving the Restoration and Water Management goals and the Settlement provisions for the Reach 2B and Mendota Pool Bypass

components. This was followed by preparing the purpose, need, and objectives; developing criteria for including actions in the Project alternatives; defining planning and implementation constraints; and identifying related projects and opportunities associated with achieving the purpose and need. These steps were applied to actions identified in Settlement provisions and to comments received during the public scoping process to identify a range of alternatives to be addressed. As a result of this process, several potential actions were eliminated from consideration, and the reasonable range of initial alternatives was identified. This process and the alternatives eliminated from consideration are summarized here and described in greater detail in the Project Description TM, Attachment A – Initial Alternatives Evaluation (SJRRP 2012).

2.3.1 Pre-Initial Options Analysis

Pre-initial options analysis included concepts suggested during the Project scoping meetings and other concepts suggested within the Project team.

Some actions suggested during the scoping process and considered by the Project Team were retained for inclusion in the Project initial options, while others were not retained for inclusion because they would not meet the Project purposes, needs, goals, and objectives. The actions suggested during the scoping process, and associated screening information, are summarized below.

- Mitigation for flood impacts: No alterations to flood management operations or to the service level of existing flood control facilities (such as design capacity and levee stability) are included in the Project. Mitigation of flood risks not generated by the Project would be beyond the scope of the Project. Local flooding conditions would be improved through increased capacity within the channel and floodplain and improved levees. Alterations to existing flood control facilities (such as the Chowchilla Bifurcation Structure) would provide at least the same level of service as the existing features and would require no changes to operations.
- Evaluation and redesign of the Columbia-Mowry Distribution System including facility access, operations and maintenance, pumps, pipelines, and power: Modifications to existing canals, pumps, pipelines, access, and power are limited to those relocations necessary to construct the Project. The Project would not include evaluation or redesign of system components outside of those potentially impacted by the Project.
- No interruption of water deliveries: The Project goals and objectives include providing water deliveries up to 2,500 cfs within Reach 2B from the San Joaquin River to the Mendota Pool; however, the availability to provide the contracted water amounts from any particular source is beyond the scope of the Project.
- Acquire land to support recreation, tourism, flora, fauna, and groundwater recharge: The purpose of the Project does not include independently supporting recreation, tourism, flora (other than riparian habitat), fauna (other than salmon and other native fishes), or groundwater recharge, so land would not be acquired solely for these purposes. However, opportunities may exist to support these functions in conjunction with or incidental to implementation of the Project, and

land acquired to meet the Project purposes, needs, goals, and objectives may also benefit recreation, tourism, flora, fauna, and groundwater recharge.

- Shortening channel distance to reduce levee length and reduce maintenance costs: Shortening of the river channel or the bypass alignments would not meet the purpose and need of the Project and may cause considerable negative effects to habitat, geomorphology, and sediment continuity in the reach that would result from shortening, or straightening, the channel.
- Installing a cutoff channel before the river bends just downstream of the Chowchilla Bifurcation Structure to reduce flooding toward Hwy 180: No alterations to flood management operations are included in the Project, and mitigation for flood risks not generated by the Project would be beyond the scope of the Project. Local flooding conditions could be improved through increased capacity within the channel and floodplain and improved levees.
- Installing a wall across the river in Reach 3 just below Mendota Dam and diverting water to Mendota Pool: This action would not meet the purpose and need of the Settlement as it would not provide a bypass around the Pool.
- Allow salmon in the Pool and Chowchilla Bypass: The extent to which fish would enter or be screened out of the Chowchilla Bypass would be beyond the scope of the Project but will be considered as part of other Program actions. Fish screening upstream of Reach 2B diversions to Mendota Pool was included.
- Include provisions to allow for Mendota Dam maintenance: Maintenance of Mendota Dam as it relates to operating the Project is included (e.g., removing sediment to operate the Short Canal); however, general maintenance of the structure and its equipment is beyond the purpose, need, and scope of the Project.
- Avoid bifurcation of future flows (require all flows from Reach 2A to be conveyed to Reach 3): The Settlement requires Restoration Flows in Reach 2B and in downstream reaches, but it does not require flood conveyance in Reach 2B, and diversion of flood flows into the Chowchilla Bypass is required to meet existing flood operation guidelines. The flexibility to divert flows to Mendota Pool is also required to meet potential Exchange Contract water deliveries.
- Fish screens in Mendota Pool (instead of bypassing the Pool): This action would not meet the purpose and need of the Settlement as it would not provide a bypass around the Pool. In addition, the maintenance, reliability of fish screens for all Pool connections would not perform as well as other alternatives.
- Evaluate all alternatives that avoid impacts to wetlands: The extent of impact to existing wetlands was considered in the alternatives evaluation process.
- Avoid dredging or filling in waters of the United States: Filling in waters of the United States would be minimized to the extent possible and was considered in the alternatives evaluation process.
- Address effects of the Project on Milburn Pond: The Project does not affect Milburn Pond.

- Do not reintroduce salmon in order to protect existing riparian habitat: Existing riparian habitat was considered in the alternatives evaluation process. Not reintroducing salmon would be contrary to the Settlement.

Some additional options exist that were not part of the scoping process, but were also considered by the Project Team and not retained for inclusion in the Project initial options because they would not meet the Project purposes, needs, goals, and objectives. These include the following:

- Construction of levees to withstand a 200-year flood: Eliminated because existing levees in the Project area are not part of the Lower San Joaquin River Flood Control Project and providing 200-year flood protection is beyond the scope of the Project and would create secondary flood impacts upstream and downstream of the Project area.

2.3.2 Pre-Evaluation Screening

During the concept refinement phase of the Project, some of the initial options were revised, refined, or eliminated from further consideration. The concepts considered and eliminated from further consideration prior to the alternatives evaluation are described below. Many concepts were refined or revised during appraisal-level design before moving into the alternatives evaluation; those refinements are described in the Project Description TM Attachment A – Alternatives Evaluation Section 5.2 (SJRRP 2012).

Bottomless Arch Culverts

Bottomless arch culverts were considered in the Initial Options TM as a potential method of improving the crossing at San Mateo Avenue. However, based upon further consideration, bottomless arch culverts were found to be too difficult to implement in the sand bed channel of Reach 2B because the culverts would require substantial undercut for foundation work, the culverts would potentially require a concrete floor to stabilize the structures during high flows, and could have an unacceptable failure rate. In addition, less expensive and equally beneficial options are available (i.e., concrete box culverts).

Corrugated Metal Pipe Culverts

Corrugated metal pipe culverts were considered in the Initial Options TM as a potential method of improving the crossing at San Mateo Avenue. However, based upon further consideration, corrugated metal pipe culverts were found to be difficult to design for the fish passage requirements and they may have a shortened lifespan due to the corrosive nature of the soils in the Project area.

Bridge

A bridge was considered in the Initial Options TM as a potential type of crossing for the San Mateo Avenue crossing. However, based upon further consideration, both a box culvert crossing and a bridge crossing were found to be capable of meeting the fish passage requirements, but the bridge is significantly more expensive. Therefore, the bridge crossing was eliminated from further consideration.

Floodplain Vegetation Types

In the Initial Options TM, several floodplain vegetation types were considered: fully grassed floodplain, forested riparian fringe along the river with a grassed floodplain, and fully forested floodplain. Based upon further review during concept refinement, the floodplain vegetation concept used in the hydraulics modeling was revised to a mosaic type floodplain habitat including a forested riparian fringe along the river and a mixture of grasslands, scrub, and trees on the floodplain. The mosaic floodplain habitat was more typically found along the river historically and can be found in other parts of the San Joaquin Valley today.

Floodplain Recontouring

As part of the Initial Options development, recontouring of the entire floodplain to allow inundation of large areas at lower flows was considered. Based upon further review during concept refinement, this concept provided less or similar benefit as the select floodplain grading included in the Project alternatives. Wholesale recontouring would not increase the habitat diversity on the floodplain and thus would not provide increased benefits to fish. However, it would require excavation of much larger quantities of material and thus would increase costs. Wholesale recontouring also has the potential to decrease the area of inundation and cause erosion along the channel. Wholesale floodplain recontouring was therefore eliminated from further consideration.

Older Levee Setbacks

During concept refinement, the levee alignments presented in the Initial Options TM were refined and revised and one alignment was eliminated: Initial Option FP-1. Initial Option FP-1 was found to not sufficiently meet the Settlement requirements to provide floodplain and riparian habitat in Reach 2B. The other levee alignments were modified to account for property lines, field lines, infrastructure, flow and sediment continuity purposes, and to add a minimum 300-foot buffer, where appropriate, between the channel and levee to protect the levee from lateral channel migration and erosion.

Mendota Dam Removal

The Fisheries Management Workgroup asked the lead agencies to consider removing Mendota Dam as part of the Fresno Slough Dam Initial Alternative. Based upon further consideration and analysis, the lead agencies decided not to remove the dam because it provides a grade control point between Reach 3 and Reach 2B. Without the dam, the channel base level would be lowered and incision could migrate upstream through Reach 2B (Tetra Tech 2011). This could jeopardize passage conditions at the structures in the Project area such as at San Mateo Avenue and Chowchilla Bifurcation Structure where channel grades would potentially be lowered by up to approximately 4.7 feet and 1.9 feet, respectively, effectively relocating the grade-control point. Lowering the base-level would also eliminate overbank flow during all but the highest flows (Tetra Tech 2011). Furthermore, structural stability of existing and proposed structures could be compromised by the decreased bed elevations and resulting scour.

Floating Picket Weir

A floating picket weir was considered in the Initial Options TM as a potential method of providing a fish exclusion barrier at the downstream end of the Mendota Pool Bypass

Channel to direct fish into the Bypass. Based upon further consideration, this option was eliminated due to the magnitude of flows expected to be seen at the barrier location and this type of weir not being appropriate for such high flows.

Behavioral Barrier

Behavioral fish barriers were investigated during the appraisal-level design as a means of providing an exclusion/directional barrier at the downstream end of the Mendota Pool Bypass Channel to direct upmigrating adult salmon into the bypass channel and away from the base of Mendota Dam. A system to reroute irrigation flows from Mendota Dam to downstream of the barrier would be included with this concept, leaving slack water between the end of the bypass channel and the Dam. Behavioral barrier systems are a developing technology, but two main types of barriers have been implemented on other rivers: electric barriers and acoustic barriers. Both types of barriers have significant drawbacks for implementation in the Project.

Electric barriers generate an electric current through the water across a channel in order to deter fish. Based on existing and previous installations, electric barriers were found to present potential unavoidable electric shock hazards for fish (target and non-target species), other animals, people, and watercraft. Often target fish species either made it past the barrier or were killed. Velocities and depths need to be consistent for the barrier to be effective; something that has proven difficult on reaches with moveable beds and those with variable flows. Velocities also need to be sufficient to sweep stunned fish out of the barrier, which may be difficult in the low slope, low velocity Reach 3. Some programs are considering replacing their electric barriers with different technologies. For all these reasons, the electric barrier is not recommended.

Acoustic barriers use a sound signal contained in a bubble curtain of air to deter fish; acoustic barriers may also incorporate the use of strobes and lights to deter fish. There are few existing installations of acoustic barriers, but they have been found to be most effective on juvenile fish with minimal effectiveness on adult fish. Effectiveness has also been found to decrease with increasing flows. Acoustic barrier technology is not capable of functioning during high flows such as flood releases from Pine Flat routed down Fresno Slough into Reach 3 (typically at 4,500 cfs or reach capacity). These high flows occur on an average annual frequency of 1 in 5 years, typically in wet years. Since the purpose of the Mendota Pool Bypass Barrier is to direct adult migrating salmon into the bypass at all flows, including flood flows, the acoustic barrier is not recommended.

Velocity Barrier

Based on design and hydraulic analyses, a velocity barrier at the downstream end of the Mendota Pool Bypass Channel was eliminated from further consideration because the resulting barrier would be higher than Mendota Dam, would increase the elevation in Mendota Pool between 4 and 5 feet, and would necessitate improvements to all levees on Mendota Pool and Fresno Slough.

Other Types of Fish Screens

During the appraisal-level design several types of fish screens were reviewed for their applicability to the Project for screening fish from the 2,500 cfs diversion to Mendota

Pool. The following screen design types were eliminated from further consideration due to design constraints. Horizontal flat plate screens (patented by Farmers Irrigation District in Oregon) were eliminated because they are intended for use with smaller diversions (less than 100 cfs); there are no physical model studies or field applications demonstrating that this design is capable of handling larger diversions. Traveling screens were eliminated because maintenance is a significant problem, and there are no known field applications for diversions of the Project's size. Box screens were eliminated because, while they can be sized for larger applications, they function very similarly to cylindrical screens which were considered further. Pump screens were eliminated because they are only applicable to very small diversions (less than 10 cfs).

Pump Diversion to Mendota Pool

All the proposed alternatives divert water to Mendota Pool via gravity. During the appraisal-level design, a pump diversion was also considered and preliminary costs were developed. The pump diversion was eliminated from further consideration because the capital improvement costs are nearly four times the cost of the gravity diversions. In addition, the pump diversion would rely on Mendota Dam or another barrier to form a backwatered pool, so the pump diversion would not be able to eliminate the need for a fish passage structure.

2.3.3 Initial Alternatives Screening

Two floodplain initial alternatives and two bypass initial alternatives were included in the Project description based on their comparatively better performance in the alternatives evaluation. The included alternatives were FP-2 (now called the narrow floodplain), FP-4 (now called the wide floodplain), Compact Bypass, and Fresno Slough Dam. The results of the alternatives evaluation and the initial alternatives recommended for elimination are described in the Project Description TM Attachment A – Alternatives Evaluation Section 8.0 (SJRRP 2012).

Three initial alternatives were eliminated from consideration based on the evaluation results: FP-1, FP-5, and the Settlement Alignment. These initial alternatives were eliminated because they perform relatively poorly when compared to the other initial alternatives. The remaining initial alternatives (FP-2, FP-3, FP-4, Compact Alignment, and Fresno Slough Dam) provide a better balance between benefits and impacts.

FP-1 would result in a confined channel system with high velocities and scour along the corridor requiring expensive bank revetment. Vegetation could be difficult to establish, and water depths would often be too deep to provide effective floodplain rearing and primary production benefits. Based on the results of the evaluation, FP-1 performs poorly for several reasons:

- Relatively low amounts of rearing habitat.
- Poor quality shallow water habitat.
- Relatively high capital improvement costs.
- Relatively low amounts of restoration area.

- Relatively greater risk of channel instability.
- Relatively larger nuisance seepage impacts.

FP-5 would result in large areas too shallow and dry to provide effective floodplain rearing and primary production benefits. Based on the results of the evaluation, FP-5 performs poorly for several reasons:

- Poor quality shallow water habitat.
- Relatively high restoration and land costs.
- Relatively greater land removed from production.
- Limited additional fish habitat and passage benefits for the added costs.
- Potential for fish strandings.

The Settlement Alignment provides less habitat than the Compact Alignment but with higher costs and larger land requirements. Based on the results of the evaluation, the Settlement Alignment performs poorly for several reasons:

- No additional shallow water or rearing habitat.
- Relatively high capital improvement costs.
- Relatively less restoration area.
- Relatively greater risk of channel instability.
- Relatively greater land removed from production.

One option was recommended for elimination from consideration based on the evaluation results: Bend 10 Columbia Canal Relocation. This option was recommended for elimination because it performs relatively poorly when compared to the Bend 10 levee revetment, which provides a better balance between benefits and impacts.

Based on the results of the evaluation, the Bend 10 Columbia Canal Relocation option performs poorly for several reasons:

- Additional land acquisition is required.
- More land removed from production.
- Relatively greater environmental impacts.

3.0 Considerations for Describing the Affected Environment and Environmental Consequences

The Project study area is broadly defined to ensure evaluation of potential direct, indirect, and cumulative effects. The areas where direct, indirect, and cumulative effects may occur differ according to resource area; therefore, the geographic range described varies by resource. Resources are generally described in relatively more detail where direct effects may occur and in relatively less detail where indirect effects are anticipated. The information in this chapter was obtained from technical studies prepared by the U.S. Department of the Interior, Bureau of Reclamation (Reclamation). Additional information was obtained from published environmental and planning documents, books, journals articles, websites, field surveys, and communications with technical experts. Descriptions of the affected environment are organized geographically.

3.1 Study Area

The study area for this Environmental Impact Statement/Report (EIS/R) includes areas that may be affected directly, indirectly, or cumulatively by implementing Project alternatives. The study area has been broadly defined to ensure evaluation of potential effects within the following geographic subareas:

- Upstream reaches (e.g., Reach 2A).
- Reach 2B, Downstream reaches (e.g., Reach 3).
- Chowchilla Bypass.
- Delta-Mendota Canal.
- Mendota Pool.
- Fresno Slough.

Operational impacts could result in these geographic subareas under the Project alternatives. Construction-related impacts would result in the Project area under the Project alternatives. Construction-related impacts would not result in other geographic subareas. The geographic subareas are described briefly below.

3.1.1 Reach 2

Reach 2 begins at Gravelly Ford and extends approximately 24 miles downstream to the Mendota Pool, continuing the boundary between Fresno and Madera counties. This reach is a meandering, low-gradient channel. Reach 2 is subdivided at the Chowchilla Bifurcation Structure into two subreaches, Reach 2A (upstream) and Reach 2B

(downstream). Except for the area backwatered by Mendota Dam, prior to Interim Flows, both Reach 2A and Reach 2B were dry in most months. Reach 2A is subject to extensive seepage losses. Reach 2B is a sandy channel with limited conveyance capacity.

3.1.2 Reach 3

Reach 3 begins at Mendota Dam and extends approximately 23 miles downstream to Sack Dam. Reach 3 conveys flows of up to 800 cubic feet per second (cfs) from the Mendota Pool for diversion to the Arroyo Canal at Sack Dam, maintaining year-round flow in a meandering channel with a sandy bed. Flood flows from the Kings River are conveyed to Reach 3 via Fresno Slough and Mendota Dam. This reach continues the boundary between Fresno and Madera counties. The sandy channel meanders through a predominantly agricultural area, and diversion structures are common in this reach.

3.1.3 Chowchilla Bypass

The Chowchilla Bifurcation Structure at the head of Reach 2B regulates the flow split between the San Joaquin River and the Chowchilla Bypass. The Chowchilla Bifurcation Structure consists of two control structures: one at the head of the Chowchilla Bypass and one across the San Joaquin River at RM 216 (see Figure 3-1). The structure is operated depending on flows in the San Joaquin River, flows from the Kings River system via Fresno Slough, water demands in Mendota Pool, and seasonality. Tributaries to the Chowchilla Bypass include the Fresno River and Berenda Slough. The Chowchilla Bypass extends to the confluence of Ash Slough, which marks the beginning of the Eastside Bypass.

3.1.4 Delta-Mendota Canal

The Delta-Mendota Canal conveys water from the Jones Pumping Plant in the south Delta to agricultural lands in the San Joaquin Valley. Water not delivered directly from the Delta-Mendota Canal is diverted at the O'Neill Pumping Plant and O'Neill Forebay for delivery via the San Luis Canal to Central Valley Project (CVP) contractors in the San Joaquin Valley, or to storage in San Luis Reservoir for later use. Most of the rest of the water continues to the south Central Valley, with some water diverted to Santa Clara County.

3.1.5 Mendota Pool

Mendota Pool is the reservoir created by Mendota Dam and has both a San Joaquin River arm and a Fresno Slough arm (see Figure 3-2). The San Joaquin arm of Mendota Pool is the portion of Reach 2B that extends from Mendota Dam to the San Mateo Avenue crossing. The Fresno Slough arm of Mendota Pool extends several miles south of the San Joaquin River. The pool serves as a distribution point for irrigation water supplies delivered by the Delta-Mendota Canal and for refuge water supply to the Mendota Wildlife Area. Mendota Pool provides no long-term storage for water supply operations or flood management.

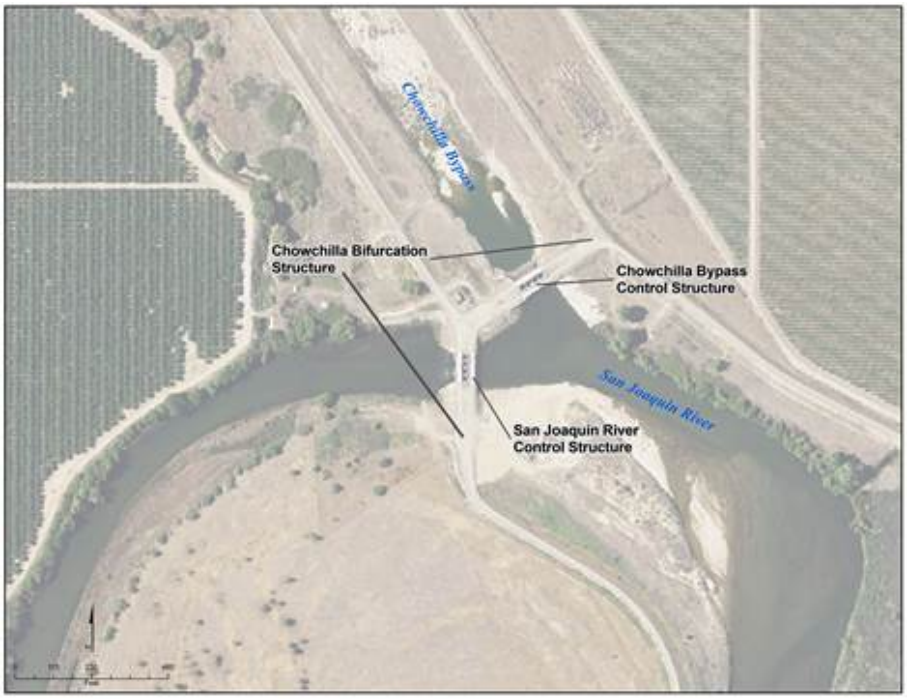

Figure 3-1.
Chowchilla Bifurcation Structure

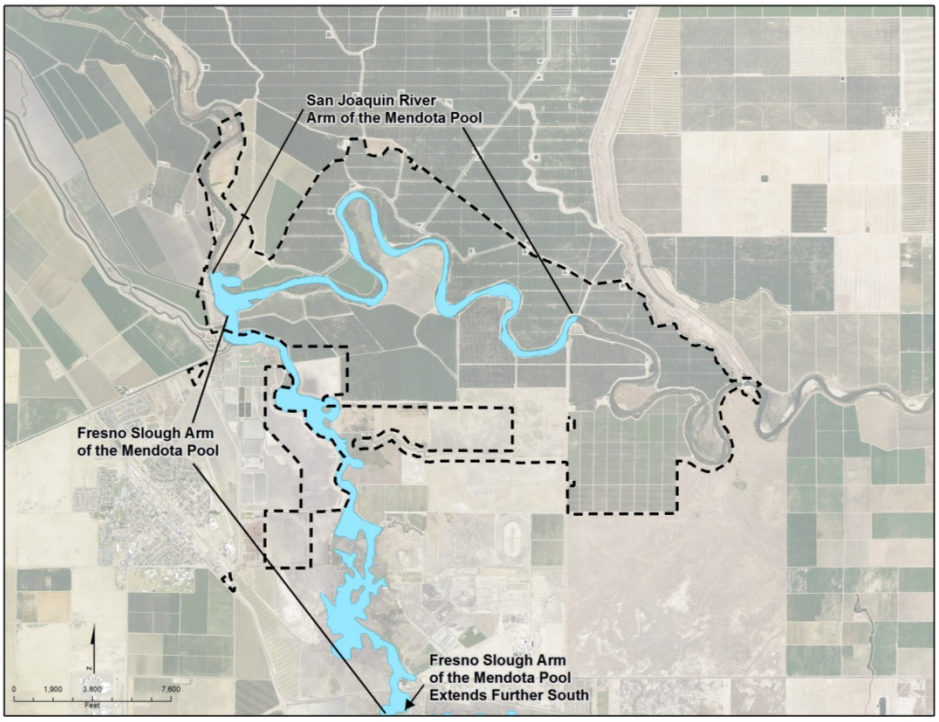

Figure 3-2.
Mendota Pool

Mendota Pool delivers water to the San Joaquin River Exchange Contractors Water Authority, other CVP contractors, wildlife refuges and management areas, and State water contractors. Water delivered to Mendota Pool from the Delta-Mendota Canal is withdrawn at seven canal or pump locations in the pool, leaving about 500 cfs to be discharged down the San Joaquin River for delivery to the Arroyo Canal, which is located about 23 miles downstream from Mendota Dam.

3.1.6 Fresno Slough

Fresno Slough is a distributary of the North Fork of the Kings River and is an intermittent stream that flows northwesterly to the San Joaquin River. James Bypass is a constructed channel that bypasses a portion of Fresno Slough. Flows in the North Fork of the Kings River consist primarily of flood releases from Pine Flat Dam located about 55 miles to the east of the confluence of Fresno Slough and the San Joaquin River. Kings River flood flows can enter Mendota Pool via Fresno Slough/James Bypass. Flows from the Kings River are regulated by Pine Flat Dam releases and the Crescent Weir.

3.2 Chapter Contents and Definition of Terms

Chapters 4.0 through 24.0 include the environmental and regulatory setting for 21 resource topics, as well as discussions of methods, significance criteria, environmental impacts, and mitigation measures for direct and indirect impacts, organized by resource topic. Chapter 25.0 discusses cumulative effects, Chapter 26.0 discusses other disclosures required by National Environmental Policy Act (NEPA) and California Environmental Quality Act (CEQA), including the Mitigation Monitoring and Reporting Program (MMRP). The NEPA/CEQA requirements are summarized in the following subsection, followed by an overview of the content of Chapters 4.0 through 24.0.

3.2.1 NEPA and CEQA Requirements

The NEPA/CEQA requirements for the environmental setting and consequences sections are similar, but not identical. These requirements are summarized below. This section also presents the organization and general assumptions used in the environmental analysis contained in this EIS/R. The reader is referred to the individual technical sections regarding specific assumptions, methodology, and significance criteria (thresholds of significance) used in the analyses.

Environmental Setting

Council on Environmental Quality (CEQ) Regulations specify that an Environmental Impact Statement (EIS) “shall succinctly describe the environment of the area(s) to be affected or created by the alternatives under consideration. The descriptions shall be no longer than necessary to understand the effects of the alternatives. Data and analyses in a statement shall be commensurate with the importance of an impact, with less important material summarized, consolidated, or simply referenced” (40 Code of Federal Regulations [CFR] 1502.15).

Section 15125, subdivision (a) of the State CEQA Guidelines states an Environmental Impact Report (EIR) “must include a description of the physical environment conditions

in the vicinity of the project, as they exist at the time that the notice of preparation is published, or if no notice of preparation is published, at the time the environmental analysis is commenced, from both a local and regional perspective. This environmental setting will normally constitute the baseline physical conditions by which the lead agency determines whether an impact is significant. The description of the environmental setting shall be no longer than is necessary to an understanding of the significant effects of the proposed project and its alternatives."

Environmental Consequences

The CEQ Regulations specify that a Federal agency preparing an EIS must consider the effects of the proposed action and alternatives on the environment; these include effects on ecological, aesthetic, historical, and cultural resources and economic, social, and health effects. Environmental effects are categorized as direct, indirect, and cumulative effects (defined below in Section 3.3.3). An EIS must also discuss possible conflicts with the objectives of Federal, State, regional, and local land use plans, policies, and controls for the area concerned; energy requirements and conservation potential; urban quality; the relationship between short-term uses of the environment and long-term productivity; and irreversible or irretrievable commitments of resources. An EIS must identify relevant, reasonable mitigation measures that are not already included in the proposed action or alternatives to the proposed action that could avoid, minimize, rectify, reduce, eliminate, or compensate for the project's adverse environmental effects (40 CFR 1502.14, 1502.16, 1508.8).

The State CEQA Guidelines explain that the environmental analysis for an EIR must evaluate impacts associated with the project and identify mitigation for any potentially significant impacts. All phases of a proposed project, including development and operation, are evaluated in the analysis. Section 15126.2, subdivision a, of the State CEQA Guidelines states in part:

> *An EIR shall identify and focus on the significant environmental effects of the proposed project. In assessing the impact of a proposed project on the environment, the Lead Agency should normally limit its examination to changes in the existing physical conditions in the affected area as they exist at the time the notice of preparation is published, or where no notice of preparation is published, at the time environmental analysis is commenced. Direct and indirect significant effects of the project on the environment shall be clearly identified and described, giving due consideration to both the short-term and long-term effects. The discussion should include relevant specifics of the area, the resources involved, physical changes, alterations to ecological systems, and changes induced in population distribution, population concentration, the human use of the land (including commercial and residential development), health and safety problems caused by the physical changes, and other aspects of the resource base such as water, historical resources, scenic quality, and public services. The EIR shall also analyze any significant environmental effects the*

> *project might cause by bringing development and people into the area affected…*

An EIR must also discuss inconsistencies between the proposed project and applicable general plans, specific plans, and regional plans (State CEQA Guidelines, § 15125, subd. (d)). An EIR must describe feasible measures that could minimize significant adverse impacts, and the measures must be fully enforceable through permit conditions, agreements, or other legally-binding instruments (State CEQA Guidelines, § 15126.4, subds. (a)(1) & (a)(2)). Mitigation measures are not required for effects that are found to be less than significant (State CEQA Guidelines, § 15126.4, subd. (a)(3)); however, this does not preclude a CEQA lead agency from adopting such mitigation measures as long as the mitigation measures are consistent with all applicable constitutional requirements as specified in State CEQA Guidelines section 15126.4, subdivision (a)(4). Mitigation measures related to historic resources and greenhouse gas (GHG) emissions are discussed in State CEQA Guidelines section 15126.4, subdivisions (b) and (c), respectively.

For Chapters 4.0 through 24.0, an "Impact Assessment Methodology" subsection is provided. This subsection describes the methods, processes, procedures, and/or assumptions used to formulate and conduct the impact analysis for each specific resource topic.

3.2.2 Significance Criteria

Significance criteria (or "thresholds of significance") are used to define the level at which an impact would be considered significant in accordance with CEQA. The thresholds applied in this joint NEPA/CEQA document encompass the factors taken into account under NEPA to determine the significance of an action in terms of its context and intensity of its effects, and also meet the more specific requirements of CEQA for significance thresholds.

Thresholds may be quantitative or qualitative; they may be based on agency or professional standards or on legislative or regulatory requirements that are relevant to the impact analysis. Generally, however, thresholds of significance are derived from Appendix G of the State CEQA Guidelines, as amended, and NEPA, where defined. Significance criteria used in this EIS/R are based on the checklist presented in Appendix G of the State CEQA Guidelines; factual or scientific information and data; and regulatory standards of Federal, State, regional, and local agencies. These thresholds also include the factors taken into account under NEPA to determine the significance of the action in terms of the context and the intensity of its effects.

An environmental document prepared to comply with CEQA must identify the significance of the environmental effects of a proposed project. Therefore, for each effect (impact), a conclusion is provided regarding its significance. A "'significant effect on the environment' means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project…" (State CEQA Guidelines, § 15382).

3.2.3 Impact Comparisons and Definitions

Under CEQA, the environmental analysis compares the alternatives under consideration, including the No-Project Alternative (referred to in this EIS/R as the No-Action Alternative), to existing conditions, defined at the time when the Notice of Preparation was published (July 13, 2009). Under NEPA, the effects of the alternatives under consideration, including the No-Action Alternative, are determined by comparing effects between alternatives and against effects from the No-Action Alternative. Consequently, baseline conditions differ between NEPA and CEQA. Under NEPA, the No-Action Alternative (i.e., expected future conditions without the project) is the baseline to which the Action Alternatives are compared, and the No-Action Alternative is compared to existing conditions. Under CEQA, existing conditions are the baseline to which all alternatives are compared.

Project impacts fall into the following categories:

- A **temporary impact** would occur only during construction. The environmental analysis addresses potentially significant impacts from the direct impact of construction at the project site, direct impact associated with site development, and indirect construction impacts associated with fill and wetland construction activities, construction traffic, etc.
- A **short-term impact** would last from the time construction ceases to within 3 years following construction.
- A **long-term impact** would last longer than 3 years following construction. In some cases, a long-term impact could be considered a permanent impact.
- A **direct impact** is an impact that would be caused by an action and would occur at the same time and place as the action.
- An **indirect impact** is an impact that would be caused by an action but would occur later in time, or at a distance that is removed from the project area (e.g., growth-inducing effects and other changes related to changes in land use patterns, and related effects on the physical environment), yet is reasonably foreseeable in the future.
- A **residual impact** is an impact that would remain after the application of mitigation.
- A **cumulative impact** is an impact taken together with other past, present, and probable future projects producing related impacts, or when two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts. A cumulative impact occurs from the change in the environment which results from the incremental impact of a project when added to other closely related past, present, and reasonably foreseeable probable future projects. Cumulative impacts can result from individually minor but collectively significant projects taking place over a period of time. Cumulative impacts are discussed in Chapter 25.0, “Cumulative Impacts.”

Impacts (and associated mitigation measures as necessary) are listed numerically and sequentially throughout each section. A statement summarizing the impact precedes the discussion of each impact. The discussion that follows the summary statement includes the analysis on which a conclusion is based regarding the significance of the impact. If the discussion is succinct, it is included in its entirety in the summary statement, and is not provided separately.

3.2.4 Impact Levels

This EIS/R uses the following terminology based on CEQA to denote the significance of each environmental effect (impact), and includes consideration of the "context" of the action and the "intensity" (severity) of its effects in accordance with NEPA guidance (40 CFR 1508.27) (CEQ Regulations for implementing NEPA do not require significance determinations):

- **No impact** indicates that the construction, operation, and maintenance of the action alternatives would not have any direct or indirect impacts on the environment. It means that no change from existing conditions would result. This impact level does not require mitigation.
- A **beneficial effect** is one that would result in a beneficial change in the physical environment. This impact level does not require mitigation.
- **A less-than-significant impact** is one that would not result in a substantial or potentially substantial adverse change in the physical environment. This impact level does not require mitigation, even if applicable measures are available, under CEQA.
- A **significant impact** is defined by CEQA as one that would cause "a substantial, or potentially substantial, adverse change in the environment" (Pub. Resources Code, § 21068). Levels of significance can vary by alternative, based on the setting and the nature of the change in the existing physical condition. Under CEQA, mitigation measures or alternatives to the proposed action must be provided, where applicable, to avoid or reduce the magnitude of significant impacts.
- A **potentially significant impact** is one that, if it were to occur, would be considered a significant impact as described above; however, the occurrence of the impact cannot be immediately determined with certainty. For CEQA purposes, a potentially significant impact is treated as if it were a significant impact. Therefore, under CEQA, mitigation measures or alternatives to the proposed action must be provided, where necessary and applicable, to avoid or reduce the magnitude of significant impacts.
- An impact may have a level of significance that is too uncertain to be reasonably determined, which would be designated **too speculative for evaluation**, in accordance with State CEQA Guidelines section 15145. Where some degree of evidence points to the reasonable potential for a significant effect, the EIS/R may explain that a determination of significance is uncertain, but is still assumed to be "potentially significant," as described above. In other circumstances, after thorough investigation, the determination of significance may still be too

speculative to be meaningful. This is an effect for which the degree of significance cannot be determined for specific reasons, such as because aspects of the impact itself are either unpredictable or the severity of consequences cannot be known at this time.

3.2.5 Mitigation Measures

Mitigation measures are presented, where feasible, to avoid, minimize, rectify, reduce, or compensate for significant and potentially significant impacts of the Action Alternatives, in accordance with the State CEQA Guidelines section 15126.4 and NEPA regulations (40 CFR 1508.20). Mitigation measures are not required for impacts identified under the No-Action Alternative because approving agencies would not be required to obtain permits or agreements if the agencies chose not to approve the project. For these reasons, mitigation measures are not provided for the No-Action Alternative even if significant impacts may result. Furthermore, no mitigation measures are proposed when an impact conclusion is "**less than significant**," "**no impact**," or "**beneficial**."

Mitigation measures are identified for project-level actions. Mitigation measures are presented in their entirety for significant and potentially significant project-level impacts and, in accordance with section 15126.4 of the State CEQA Guidelines, are fully enforceable through permit conditions, agreements, or other legally-binding instruments.

Section 15370 of the State CEQA Guidelines defines mitigation as follows:

- Avoiding the impact altogether by not taking a certain action or parts of an action.
- Minimizing impacts by limiting the degree or magnitude of the action and its implementation.
- Rectifying the impact by repairing, rehabilitating, or restoring the impacted environment.
- Reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action.
- Compensating for the impact by replacing or providing substitute resources or environments.

In accordance with Public Resources Code section 21081.6, subdivision (a), if a State agency approves the project actions, that agency would adopt a reporting or monitoring program at the time that it makes its CEQA findings. The purpose of the MMRP (see Chapter 26.0) is to ensure that the mitigation measures adopted as part of project approval would be complied with during project construction and implementation. The MMRP would identify each of the mitigation measures for project-level actions, and describe the party responsible for monitoring (Reclamation, California State Lands Commission, or other, as appropriate), the time frame for implementation, and the program for monitoring compliance.

3.2.6 Significance After Mitigation

For each significant and potentially significant impact, following the presentation of proposed mitigation measures, the significance of the impact after mitigation is stated.

Where sufficient feasible mitigation is not available to reduce impacts to a less-than-significant level, the impacts are identified as "significant and unavoidable." Under State CEQA Guidelines section 15091, subdivision (a), a public agency cannot approve or carry out a project for which an EIR has been certified which identifies one or more significant environmental effects of the project unless the public agency makes one or more written findings for each of those significant effects, accompanied by a brief explanation of the rationale for each finding. In accordance with State CEQA Guidelines section 15093, when an agency approves a project which will result in the occurrence of significant effects which are identified in the Final EIR but are not avoided or substantially lessened, the agency shall make a "statement of overriding considerations" supported by substantial evidence in the record that states in writing the specific reasons to support its action based on the final EIR and/or other information in the record.

For the No-Action and Action Alternatives, significant and unavoidable impacts are also summarized in Chapter 27.0, "Other NEPA and CEQA Considerations."

3.2.7 Relationship between Short-Term Uses of the Environment and Maintenance and Enhancement of Long-Term Productivity

NEPA requires that an EIS include a discussion of the relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity. For the No-Action and Action Alternatives, this discussion is provided in Chapter 26.0, "Other NEPA and CEQA Considerations."

3.2.8 Irreversible and Irretrievable Commitments of Resources

NEPA requires that an EIS include a discussion of the irreversible and irretrievable commitments of resources that may be involved if the project is implemented. Similarly, the State CEQA Guidelines requires the identification and analysis of significant irreversible environmental changes that would be involved if the project is implemented. For joint CEQA/NEPA documents, the EIS/R must analyze and justify the extent to which the Project will commit nonrenewable resources to uses that future generations will probably be unable to reverse (Pub. Resources Code, § 21100(a); State CEQA Guidelines, §§ 15126, Subd. (c), 15126.2, Subd. (c), and 15127).

The irreversible and irretrievable commitment of resources is the permanent loss of resources for future or alternative purposes. Irreversible and irretrievable commitments of resources occur when resources cannot be recovered or recycled or when resources are consumed or reduced to unrecoverable forms. For the No-Action and Action Alternatives, irreversible and irretrievable commitments of resources are discussed in Section 26.3, "Irreversible and Irretrievable Commitments of Resources."

3.3 Resources Eliminated from Further Analysis

CEQA and the State CEQA Guidelines provide for the identification and elimination from detailed study the issues that are not significant or that have been covered by prior environmental review (Pub. Resources Code, § 21002.1, State CEQA Guidelines, § 15143). The CEQ Regulations provide similar provisions (40 CFR 1501.7(a)(3)).

During initial scoping with the public and governmental agencies, and based on information obtained through literature review, agency correspondence, consultations, and field data collection, it was determined that Indian Trust Assets could be eliminated from detailed study because Indian Trust Assets are not found in the Project area. Therefore, with the exception of Indian Trust Assets, all other resource areas covered by NEPA and CEQA are addressed in this EIS/R.

This page left blank intentionally.

4.0 Air Quality

This chapter describes the environmental and regulatory setting for air quality, as well as environmental consequences and mitigation, as they pertain to implementation of the Project alternatives. Greenhouse gas emissions are discussed in Chapter 8.0, "Climate Change and Greenhouse Gas Emissions." The discussion of existing conditions and the potential impacts of the Project alternatives on air quality encompass Reach 2B, Fresno and Madera counties, and the San Joaquin Valley Air Basin (SJVAB).

4.1 Environmental Setting

The Project area and vicinity are located in Fresno and Madera counties, which are part of the SJVAB. The SJVAB also comprises all of Merced, Kings, San Joaquin, Stanislaus, and Tulare counties and the valley portion of Kern County.

4.1.1 Ambient Air Quality

Ambient concentrations of air pollutants, contaminants, and odors are determined by the amount of emissions released by sources and the atmosphere's ability to transport and dilute such emissions. Natural factors which affect transport and dilution include terrain, wind, atmospheric stability, and the presence of sunlight. Therefore, existing air quality conditions in the area are determined by such natural factors as topography, meteorology, and climate, in addition to the amount of emissions released by existing sources, as discussed separately below.

Climate, Meteorology, and Topography

The SJVAB, which occupies the southern half of the Central Valley, is approximately 250 miles long and, on average, 35 miles wide. The SJVAB is a well-defined climatic region with distinct topographic features on three sides. The Coast Range is located on the western border of the SJVAB. The San Emigdio Mountains, which are part of the Coast Range, and the Tehachapi Mountains, which are part of the Sierra Nevada, are both located on the south side of the SJVAB. The Sierra Nevada forms the eastern border of the SJVAB. The northernmost portion of the SJVAB is San Joaquin County. There is no topographic feature delineating the northern edge of the basin. The SJVAB can be considered a "bowl" open only to the north.

The SJVAB is basically flat with a downward gradient in terrain to the northwest. Air flows into the SJVAB through the Carquinez Strait, the only breach in the western mountain barrier, and moves across the Sacramento–San Joaquin Delta from the San Francisco Bay area. The mountains surrounding the SJVAB create a barrier to airflow, which leads to the entrapment of air pollutants when meteorological conditions are unfavorable for transport and dilution. As a result, the SJVAB is highly susceptible to pollutant accumulation over time.

The inland Mediterranean climate type of the SJVAB is characterized by hot, dry summers and cool, rainy winters. The climate is a result of the topography and the strength and location of a semi-permanent, subtropical high-pressure cell. During summer, the Pacific high-pressure cell is centered over the northeastern Pacific Ocean resulting in stable meteorological conditions and a steady northwesterly wind flow. Cold ocean water upwells from below to the surface because of the northwesterly flow, producing a band of cold water off the California coast.

Daily summer high temperatures often exceed 100 degrees Fahrenheit (°F), averaging in the low 90s in the north and high 90s in the south. In the entire SJVAB, daily summer high temperatures average 95ºF. Over the last 30 years, temperatures in the SJVAB averaged 90°F or higher for 106 days a year, and 100°F or higher for 40 days a year. The daily summer temperature variation can be as high as 30°F (San Joaquin Valley Air Pollution Control District [SJVAPCD] 2002). In winter, the Pacific high-pressure cell weakens and shifts southward, resulting in wind flow offshore and allowing storm systems to move in from the Pacific Ocean. Average high temperatures in the winter are in the 50s, but lows in the 30s and 40s can occur on days with persistent fog and low cloudiness. The average daily low temperature in the winter is 45°F (SJVAPCD 2002).

A majority of the precipitation in the SJVAB occurs as rainfall during winter storms. The rare occurrence of precipitation during the summer is in the form of convective rain showers. The amount of precipitation in the SJVAB decreases from north to south primarily because the Pacific storm track often passes through the northern portion of the SJVAB, while the southern portion remains protected by the Pacific high-pressure cell. Stockton, in the north, receives about 20 inches of precipitation per year, while Fresno, in the center, receives about 10 inches per year, and Bakersfield, at the southern end of the valley, receives less than 6 inches per year. Average annual rainfall for the entire SJVAB is approximately 9.25 inches on the valley floor (SJVAPCD 2002).

The winds and unstable atmospheric conditions associated with the passage of winter storms result in periods of low air pollution and excellent visibility. Precipitation and fog tend to reduce or limit some pollutant concentrations. For instance, clouds and fog block sunlight, which is required to fuel photochemical reactions that form ozone. Because carbon monoxide (CO) is partially water-soluble, precipitation and fog also tend to reduce concentrations in the atmosphere. In addition, respirable particulate matter with an aerodynamic diameter of 10 micrometers or less (PM_{10}) can be washed from the atmosphere through wet deposition processes (e.g., rain). However, between winter storms, high pressure and light winds lead to the creation of low-level temperature inversions and stable atmospheric conditions resulting in the concentration of air pollutants (e.g., CO and PM_{10}).

Summer is considered the ozone season in the SJVAB. This season is characterized by poor air movement in the mornings and by longer daylight hours, which provide a plentiful amount of sunlight to fuel photochemical reactions between reactive organic gases (ROG) and nitrogen oxides (NO_X), which result in ozone formation. During the summer, wind speed and direction data indicate that summer wind usually originates at

the north end of the San Joaquin Valley and flows in a south-southeasterly direction through Tehachapi Pass and into the Southeast Desert Air Basin (SJVAPCD 2002).

Criteria Air Pollutants

Concentrations of ozone, CO, nitrogen dioxide (NO_2), sulfur dioxide (SO_2), PM_{10}, fine particulate matter with an aerodynamic resistance diameter of 2.5 micrometers or less ($PM_{2.5}$), and lead are used as indicators of ambient air quality conditions. Because these are the most prevalent air pollutants known to be deleterious to human health, and because there is extensive documentation available on health-effects criteria for these pollutants, they are commonly referred to as "criteria air pollutants."

A brief description of each criteria air pollutant, including source types, health effects, and future trends, is provided below along with the most current attainment area designations and monitoring data for the Project area and vicinity.

Ozone

Ozone is a photochemical oxidant, a substance whose oxygen combines chemically with another substance in the presence of sunlight, and the primary component of smog. Ozone is not directly emitted into the air, but is formed through complex chemical reactions between precursor emissions of ROG and NO_X in the presence of sunlight. ROG are volatile organic compounds that are photochemically reactive. ROG emissions result primarily from incomplete combustion and the evaporation of chemical solvents and fuels. NO_X are a group of gaseous compounds of nitrogen and oxygen that results from the combustion of fuels. As a highly reactive molecule, ozone readily combines with many different components of the atmosphere. Consequently, high levels of ozone tend to exist only while high ROG and NO_X levels are present to sustain the ozone formation process. Once the precursors have been depleted, ozone levels rapidly decline. Because these reactions occur on a regional scale, ozone is a regional pollutant.

Ozone located in the upper atmosphere (stratosphere) acts in a beneficial manner by shielding the earth from harmful ultraviolet radiation that is emitted by the sun. However, ozone located in the lower atmosphere (troposphere) is a major health and environmental concern. Meteorology and terrain play a major role in ozone formation. Generally, low wind speeds or stagnant air coupled with warm temperatures and clear skies provide the optimum conditions for ozone formation. As a result, summer is generally the peak ozone season. Because of the reaction time involved, peak ozone concentrations often occur far downwind of the precursor emissions. In general, ozone concentrations over or near urban and rural areas reflect an interplay of emissions of ozone precursors, transport, meteorology, and atmospheric chemistry.

The adverse health effects associated with exposure to ozone impact primarily the respiratory system. Scientific evidence indicates that ambient levels of ozone affect not only sensitive receptors, such as asthmatics and children, but healthy adults as well. Exposure to ambient levels of ozone ranging from 0.10 to 0.40 parts per million (ppm) for 1 to 2 hours has been found to significantly alter lung functions by increasing respiratory rates and pulmonary resistance, decreasing tidal volumes (the amount of air inhaled and exhaled), and impairing respiratory mechanics. Ambient levels of ozone

above 0.12 ppm are linked to symptomatic responses that include such symptoms as throat dryness, chest tightness, headache, and nausea. In addition to the above adverse health effects, evidence also exists relating ozone exposure to an increase in permeability of respiratory epithelia; such increased permeability leads to an increased response of the respiratory system to challenges and a decrease in the immune system's ability to defend against infection.

Although ozone problem in the SJVAB ranks among the most severe in the State, the ozone precursor emissions of ROG and NO_X have decreased over the past several years because of more stringent motor vehicle standards and cleaner burning fuels. From 1992 to 2012, the maximum peak 8-hour indicator decreased by 6 percent. The number of national 8-hour exceedance days has declined by 32 percent (California Air Resources Board [ARB] 2014).

Carbon Monoxide

CO is a colorless, odorless, and poisonous gas produced by incomplete burning of carbon in fuels, primarily from mobile (transportation) sources. In fact, 86 percent of the nationwide CO emissions are from mobile sources; the other 14 percent consists of CO emissions from wood-burning stoves, incinerators, and industrial sources (U.S. Environmental Protection Agency [EPA] 2013a).

CO enters the bloodstream through the lungs by combining with hemoglobin, which normally supplies oxygen to the cells. However, CO combines with hemoglobin much more readily than oxygen does, resulting in a drastic reduction in the amount of oxygen available to the cells. Adverse health effects associated with exposure to CO concentrations include such symptoms as dizziness, headaches, and fatigue. CO exposure is especially harmful to individuals who suffer from cardiovascular and respiratory diseases (EPA 2014).

The highest concentrations are generally associated with cold, stagnant weather conditions that occur during the winter. In contrast to problems caused by ozone, which tends to be a regional pollutant, CO problems tend to be localized.

Nitrogen Dioxide

NO_2 is a brownish, highly reactive gas that is present in all urban environments. The major human-made sources of NO_2 are combustion devices, such as boilers, gas turbines, and mobile and stationary reciprocating internal combustion engines. Combustion devices emit primarily nitric oxide (NO), which reacts through oxidation in the atmosphere to form NO_2 (EPA 2014). The combined emissions of NO and NO_2 are referred to as NO_X and reported as equivalent NO_2. Because NO_2 is formed and depleted by reactions associated with ozone, the NO_2 concentration in a particular geographical area may not be representative of the local NO_X emission sources.

Inhalation is the most common route of exposure to NO_2. Because NO_2 has relatively low solubility in water, the principal site of toxicity is in the lower respiratory tract. The severity of the adverse health effects depends primarily on the concentration inhaled rather than the duration of exposure. An individual may experience a variety of acute

symptoms, including coughing, difficulty with breathing, vomiting, headache, and eye irritation during or shortly after exposure. After a period of approximately 4 to 12 hours, an exposed individual may experience chemical pneumonitis or pulmonary edema with breathing abnormalities, cough, cyanosis, chest pain and rapid heartbeat. Severe, symptomatic NO_2 intoxication after acute exposure has been linked on occasion with prolonged respiratory impairment with such symptoms as chronic bronchitis and decreased lung functions (EPA 2014).

Sulfur Dioxide

SO_2 is produced by such stationary sources as coal and oil combustion, steel mills, refineries, and pulp and paper mills. The major adverse health effects associated with SO_2 exposure pertain to the upper respiratory tract. SO_2 is a respiratory irritant with constriction of the bronchioles occurring with inhalation of SO_2 at 5 ppm or more. On contact with the moist, mucous membranes, SO_2 produces sulfurous acid (H_2SO_3), which is a direct irritant. Concentration, rather than duration of the exposure, is an important determinant of respiratory effects. Exposure to high SO_2 concentrations may result in edema of the lungs or glottis and respiratory paralysis.

Particulate Matter

Respirable particulate matter with an aerodynamic diameter of 10 micrometers or less is referred to as PM_{10}. PM_{10} consists of particulate matter emitted directly into the air, such as fugitive dust, soot and smoke from mobile and stationary sources, construction operations, fires and natural windblown dust, and particulate matter formed in the atmosphere by condensation and/or transformation of SO_2 and ROG (EPA 2014). $PM_{2.5}$ is a subgroup of PM_{10}, consisting of smaller particles that have an aerodynamic diameter of 2.5 micrometers or less.

PM_{10} emissions in the SJVAB are dominated by emissions from area-wide sources, primarily fugitive dust from vehicle travel on unpaved and paved roads, waste burning, and residential fuel combustion. The adverse health effects associated with PM_{10} depend on the specific composition of the particulate matter. For example, health effects may be associated with metals, polycyclic aromatic hydrocarbons and other toxic substances adsorbed onto fine particulate matter (referred to as the “piggybacking effect”), or with fine dust particles of silica or asbestos. Generally, adverse health effects associated with PM_{10} may result from both short-term and long-term exposure to elevated concentrations and may include breathing and respiratory symptoms, aggravation of existing respiratory and cardiovascular diseases, alterations to the immune system, carcinogenesis, and premature death (EPA 2014). $PM_{2.5}$ poses an increased health risk because the particles can deposit deep in the lungs and may contain substances that are particularly harmful to human health.

Direct emissions of $PM_{2.5}$ remained relatively unchanged between 2000 and 2005, was reduced to current levels by 2010, and are projected by the ARB to remain unchanged through 2035 (ARB 2014). Annual average $PM_{2.5}$ concentrations in the SJVAB show a definite downward trend from 1999 through 2011. Annual average concentrations have dropped 26 percent between 1999 and 2011 (ARB 2014). $PM_{2.5}$ emissions in the SJVAB are dominated by emissions from the same area-wide sources as PM_{10}.

Lead

Lead is a metal found naturally in the environment, as well as in manufactured products. The major sources of lead emissions have historically been mobile and industrial sources. As a result of the phase-out of leaded gasoline, as discussed in detail below, metal processing is currently the primary source of lead emissions. The highest levels of lead in air are generally found near lead smelters. Other stationary sources are waste incinerators, utilities and lead-acid battery manufacturers.

Twenty years ago, mobile sources were the main contributor to ambient lead concentrations in the air. In the early 1970s, the EPA set national regulations to gradually reduce the lead content in gasoline. In 1975, unleaded gasoline was introduced for motor vehicles equipped with catalytic converters. The EPA banned the use of leaded gasoline in highway vehicles in December 1995 (EPA 2014).

As a result of the EPA's regulatory efforts to remove lead from gasoline, emissions of lead from the transportation sector have declined dramatically (95 percent between 1980 and 1999) and levels of lead in the air decreased by 94 percent between 1980 and 1999. The major sources of lead emissions to the air are ore and metals processing and piston-engine aircraft operating on leaded aviation gasoline (EPA 2014). The National Health and Nutrition Examination Survey have found a steady decrease in the levels of lead in people's blood since 1976. This decline has been attributed to the move from leaded to unleaded gasoline (EPA 2013b).

The decrease in lead emissions and ambient lead concentrations over the past 25 years is California's most dramatic success story with regard to air quality management. The rapid decrease in lead concentrations can be attributed primarily to phasing out the lead in gasoline. This phase-out began during the 1970s, and subsequent ARB regulations have virtually eliminated all lead from gasoline now sold in California. All areas of the State are currently designated as attainment for the State lead standard (the EPA does not designate areas for the national lead standard). Although the ambient lead standards are no longer violated, lead emissions from stationary sources still pose "hot spot" problems in some areas. As a result, the ARB identified lead as a toxic air contaminant.

Emission Sources

With respect to the emissions of criteria air pollutants within Fresno and Madera counties, mobile sources are the largest contributor to the estimated annual average levels of CO and NO_X accounting for approximately 68 percent and 83 percent, respectively, of the total emissions. Area-wide sources account for approximately 22 percent, 90 percent, and 73 percent of ROG, PM_{10} and $PM_{2.5}$ emissions, respectively, in the two counties (Fresno and Madera) (ARB 2013a). Table 4-1 shows the estimated annual average emissions for the SJVAB in 2012.

Key:

CO = carbon monoxide

NOx = nitrogen oxides

PM = particulate matter

PM_{10} = particulate matter smaller than or equal to 10 microns in diameter

$PM_{2.5}$ = particulate matter smaller than or equal to 2.5 microns in diameter

ROG = reactive organic gas

SO_x = sulfur oxides

SJVAB = San Joaquin Valley Air Basin

TOG = total organic gas

Similar to most agricultural areas of the Central Valley, the Project area and vicinity have existing air quality emissions of PM, NO_X, and ROG due, in part, to active agricultural land use. Agricultural field operations, such as tilling, planting, weeding, fertilizing, harvesting, and spreading of manure or compost can produce air pollution emissions. These emissions can be directly emitted from the action of wheels and machinery on soil

or from engine operation and fuel combustion. For example, wind erosion can transport dust after tillage (increasing PM_{10}) and fertilizer used for crops release ammonia to the atmosphere, which mixes with other emissions to form microscopic airborne particles (increasing $PM_{2.5}$).

Monitoring Station Data and Attainment Area Designations

Criteria air pollutant concentrations are measured at several monitoring stations in the SJVAB. There are two stations within proximity to the Project area. The closest is the Pump Yard station, approximately 15 miles east of the project site in Madera County, which measures ozone and NO_X. The next closest is the North Villa Avenue station in the town of Clovis, approximately 30 miles east of the Project area in Fresno County. The North Villa Avenue station measures ozone, CO, PM_{10}, $PM_{2.5}$, and NO_2. These monitoring stations are at elevations similar to the Project site, as they are located on the valley floor. Table 4-2 summarizes the air quality data from these stations for 2008 through 2012. The North Villa Avenue station concentrations are not necessarily representative of Project area concentrations because of the distance from the monitoring station to the site, but give approximate emissions levels that would be similar to the Project vicinity. Figure 4-1 shows the locations of the monitoring stations.

Both the ARB and the EPA use this type of monitoring data in relation to applicable standards to designate area attainment status for criteria air pollutants. The purpose of these designations is to identify those areas with air quality problems and thereby initiate planning efforts for improvement. The basic designation categories are nonattainment, maintenance, attainment, and unclassified. A pollutant is designated nonattainment if there was at least one violation of a Federal or State standard for that pollutant in the area, and a pollutant is designated attainment if the Federal or State standard for that pollutant was not violated at any site in the area during a three-year period. A maintenance area is an area that was previously classified as nonattainment and has subsequently demonstrated compliance with the standards. Unclassified is used in an area that cannot be classified on the basis of available information as meeting or not meeting the standards. In addition, the California designations include a subcategory of the nonattainment designation, called nonattainment-transitional. The nonattainment-transitional designation is given to nonattainment areas that are progressing and nearing attainment. The most current attainment designations for the portion of the SJVAB in the Project area and vicinity are shown in Table 4-3 for each criteria air pollutant.

The SJVAB is designated as being in nonattainment for (see Table 4-3):

- The State 1-hour ozone standard and the Federal and State 8-hour ozone standard.
- The State 24-hour and annual PM_{10} standards.
- The State annual $PM_{2.5}$ standard and the Federal 24-hour and annual $PM_{2.5}$ standards.

Notes:

[1] Measurements from the Pump Yard station (Madera County).

[2] Measurements from the North Villa Avenue station in the town of Clovis (Fresno County).

[3] State and national statistics may differ for the following reasons: State statistics are based on California approved samplers, whereas national statistics are based on samplers using Federal reference or equivalent methods. State and national statistics may therefore be based on different samplers. State statistics are based on local conditions National statistics are based on standard conditions. State criteria for ensuring that data are sufficiently complete for calculating valid annual averages are more stringent than the national criteria

[4] Measured days are those days that an actual measurement was greater than the level of the State daily standard or the national daily standard. Measurements are typically collected every 6 days. The number of days above the standard is not necessarily the number of violations of the standard for the year.

[5] National and California 8-hr CO maximum concentrations were the same for these 3 years.

Key:

hr = hour

ppm = parts per million

µg/m^3 = micrograms per cubic meter

Summary of Attainment Status Designations and Ambient Air Quality Standards in the Project Area and Vicinity

Pollutant	Averaging Time	California		National Standards[1]		
		Standards [2,3]	Attainment Status [4]	Primary [3,5]	Secondary [3,6]	Attainment Status [7]
Ozone	1-hour	0.09 ppm (180 µg/m^3)	N (Severe)	-	-	-
	8-hour	0.07 ppm (137 µg/m^3)	N	0.075 ppm (147 µg/m^3)	Same as Primary Standard	N (Extreme)
Carbon Monoxide (CO)	1-hour	20 ppm (23 mg/m^3)	A (Fresno) U (Madera, Modesto)	35 ppm (40 mg/m^3)	–	U/A
	8-hour	9 ppm (10 mg/m^3)		9 ppm (10 mg/m^3)		
Nitrogen Dioxide (NO_2)	Annual Arithmetic Mean	0.030 ppm (57 µg/m^3)	–	0.053 ppm (100 µg/m^3)	Same as Primary Standard	U/A
	1-hour	0.18 ppm (339 µg/m^3)	A	0.10 ppm (188 µg/m^3)	-	–
Sulfur Dioxide (SO_2)	Annual Arithmetic Mean	–	–	0.030 ppm (80 µg/m^3)	–	U/A
	24-hour	0.04 ppm (105 µg/m^3)	A	0.14 ppm (365 µg/m^3)	–	
	3-hour	–	–	–	0.5 ppm (1300 µg/m^3)	
	1-hour	0.25 ppm (655 µg/m^3)	A	0.075 ppm	–	–
Respirable Particulate Matter (PM_{10})	Annual Arithmetic Mean	20 µg/m^3	–	–	Same as Primary Standard	–
	24-hour	50 µg/m^3	N	150 µg/m^3		A
Fine Particulate Matter ($PM_{2.5}$) [9]	Annual Arithmetic Mean	12 µg/m^3	N	12 µg/m^3	Same as Primary Standard	N (Moderate)
	24-hour	–	–	35 µg/m^3		
Lead[8]	30-day Average	1.5 µg/m^3	A	–	–	–
	Calendar Quarter	–	–	1.5 µg/m^3	Same as Primary Standard	U/A
	Rolling 3 Month Average	–	–	0.15 µg/m^3	Same as Primary Standard	U/A
Sulfates	24-hour	25 µg/m^3	A	No National Standards		
Hydrogen Sulfide	1-hour	0.03 ppm (42 µg/m^3)	U	No National Standards		
Vinyl Chloride[8]	24-hour	0.01 ppm (26 µg/m^3)	A	No National Standards		

Table 4-3.
Summary of Attainment Status Designations and Ambient Air Quality Standards in the Project Area and Vicinity

Pollutant	Averaging Time	California		National Standards[1]		
		Standards [2,3]	Attainment Status [4]	Primary [3,5]	Secondary [3,6]	Attainment Status [7]
Visibility-Reducing Particle Matter	8-hour	Extinction coefficient of 0.23 per kilometer —visibility of 10 miles or more (0.07—30 miles or more for Lake Tahoe) because of particles when the relative humidity is less than 70 percent.	U	No National Standards		

Sources: ARB 2011a, 2011b; EPA 2013d; SJVAPCD 2011.

Notes:

[1] National standards (other than ozone, PM, and those based on annual averages or annual arithmetic means) are not to be exceeded more than once a year. The ozone standard is attained when the fourth highest 8-hour concentration in a year, averaged over 3 years, is equal to or less than the standard. The PM_{10} 24-hour standard is attained when 99 percent of the daily concentrations, averaged over 3 years, are equal to or less than the standard. The $PM_{2.5}$ 24-hour standard is attained when 98 percent of the daily concentrations, averaged over 3 years, are equal to or less than the standard. Contact the EPA for further clarification and current Federal policies.

[2] California standards for ozone, CO (except Lake Tahoe), SO_2 (1- and 24-hour), NO_2, PM, and visibility-reducing particles are values that are not to be exceeded. All others are not to be equaled or exceeded. California Ambient Air Quality Standards (CAAQS) are listed in the Table of Standards in California Code of Regulations, Title 17, section 70200.

[3] Concentration expressed first in units in which it was promulgated [i.e., parts per million (ppm) or micrograms per cubic meter ($\mu g/m^3$)]. Equivalent units given in parentheses are based upon a reference temperature of 25°C and a reference pressure of 760 torr. Most measurements of air quality are to be corrected to a reference temperature of 25°C and a reference pressure of 760 torr; ppm in this table refers to ppm by volume, or micromoles of pollutant per mole of gas.

[4] Unclassified (U): a pollutant is designated unclassified if the data are incomplete and do not support a designation of attainment or nonattainment.
Attainment (A): a pollutant is designated attainment if the State standard for that pollutant was not violated at any site in the area during a 3-year period.
Nonattainment (N): a pollutant is designated nonattainment if there was a least one violation of a State standard for that pollutant in the area.
Nonattainment/Transitional (NT): is a subcategory of the nonattainment designation. An area is designated nonattainment/transitional to signify that the area is close to attaining the standard for that pollutant.

[5] National Primary Standards: The levels of air quality necessary, with an adequate margin of safety, to protect the public health.

[6] National Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.

[7] Nonattainment (N): any area that does not meet (or that contributes to ambient air quality in a nearby area that does not meet) the national primary or secondary ambient air quality standard for the pollutant.
Attainment (A): any area that meets the national primary or secondary ambient air quality standard for the pollutant.
Unclassifiable (U): any area that cannot be classified on the basis of available information as meeting or not meeting the national primary or secondary ambient air quality standard for the pollutant.

[8] ARB has identified lead and vinyl chloride as toxic air contaminants with no threshold of exposure for adverse health effects determined. These actions allow for the implementation of control measures at levels below the ambient concentrations specified for these pollutants.

[9.] On December 14, 2012, the EPA revised the annual $PM_{2.5}$ ambient air quality standard. The value was changed from 15 ug/m3 to 12 ug/m3. Attainment designations would not be available until December 2014.

Toxic Air Contaminants

Concentrations of toxic air contaminants, or in Federal parlance hazardous air pollutants (HAPs), are also used as indicators of ambient air quality conditions. A toxic air contaminant is defined as an air pollutant that may cause or contribute to an increase in mortality or in serious illness, or that may pose a hazard to human health. Toxic air contaminants are usually present in minute quantities in the ambient air; however, their high toxicity or health risk may pose a threat to public health even at low concentrations.

According to the *California Almanac of Emissions and Air Quality* (ARB 2007a), the majority of the estimated health risk from toxic air contaminants can be attributed to relatively few compounds, the most important being particulate matter from diesel-fueled engines (diesel particulate matter). Diesel particulate matter differs from other toxic air contaminants in that it is not a single substance, but rather a complex mixture of hundreds of substances. Although diesel particulate matter is emitted by diesel-fueled internal combustion engines, the composition of the emissions varies depending on engine type, operating conditions, fuel composition, lubricating oil, and whether an emission control system is present.

Unlike the other toxic air contaminants, no ambient monitoring data are available for diesel particulate matter because no routine measurement method currently exists. However, the ARB has made preliminary concentration estimates based on a particulate matter exposure method. This method uses the ARB emissions inventory's PM_{10} database, ambient PM_{10} monitoring data and the results from several studies to estimate concentrations of diesel particulate matter. In addition to diesel particulate matter, the toxic air contaminants for which data are available that pose the greatest existing ambient risk in California are benzene, 1,3-butadiene, acetaldehyde, carbon tetrachloride, hexavalent chromium, *para*-dichlorobenzene, formaldehyde, methylene chloride, and perchloroethene.

Diesel particulate matter poses the greatest health risk among these 10 toxic air contaminants. Based on receptor modeling techniques, the ARB estimated the diesel particulate matter health risk within the SJVAB in 2000 to be 390 excess cancer cases per million people. Since 1990, the health risk of diesel particulate matter in the SJVAB has been reduced by 50 percent. Overall, levels of most toxic air contaminants have gone down since 1990 except for *para*-dichlorobenzene and formaldehyde (ARB 2007a).

According to the ARB Community Health Air Pollution Information System, there are five major existing stationary sources of toxic air contaminants within 3 miles of the Project area (ARB 2011c). In addition, vehicles on State Route 140, 165, 99, 41, and 152 are sources of diesel particulate matter and other mobile source air toxics.

Odors

Odors are generally regarded as an annoyance rather than a health hazard. However, manifestations of a person's reaction to foul odors can range from psychological (e.g., irritation, anger, or anxiety) to physiological (e.g., circulatory and respiratory effects, nausea, vomiting, and headache).

With respect to odors, the human nose is the sole sensing device. The ability to detect odors varies considerably among the population and overall is quite subjective. Some individuals have the ability to smell very minute quantities of specific substances; others may not have the same sensitivity, but may have sensitivities to odors of other substances. In addition, people may have different reactions to the same odor; an odor that is offensive to one person may be perfectly acceptable to another (e.g., fast food restaurant). An unfamiliar odor is also more likely to be detected and cause complaints than a familiar one. This is due to the phenomenon known as odor fatigue, in which a person can become desensitized to almost any odor and recognition only occurs with an alteration in the intensity.

Quality and intensity are two properties present in any odor. The quality of an odor indicates the nature of the smell experience. For instance, if a person describes an odor as flowery or sweet, then the person is describing the quality of the odor. Intensity refers to the strength of the odor. For example, a person may use the word strong to describe the intensity of an odor. Odor intensity depends on the odorant concentration in the air. When an odorous sample is progressively diluted, the odorant concentration decreases. As this occurs, the odor intensity weakens and eventually becomes so low that the detection or recognition of the odor is quite difficult. At some point during dilution, the concentration of the odorant reaches a detection threshold. An odorant concentration below the detection threshold means that the concentration in the air is not detectable by the average human.

Potential existing sources of odor include various agricultural activities in the vicinity of the Project area (e.g., dairy operations, livestock operations, and fertilizer use).

4.1.2 Sensitive Receptors

Sensitive receptors are considered those with increased exposure or risk to air pollutants and include schools, daycare facilities, elderly care establishments, medical facilities, and other areas that are populated with people considered more vulnerable to the effects of poor air quality. There are some residences located within a 1,000-foot radius of the Project footprint (Figure 4-2). Sensitive receptors shown on Figure 4-2 are single residences or a group of residences. Since this Project mostly consists of construction activities, the receptors would not be exposed to toxic air contaminants or HAPs for a long period of time.

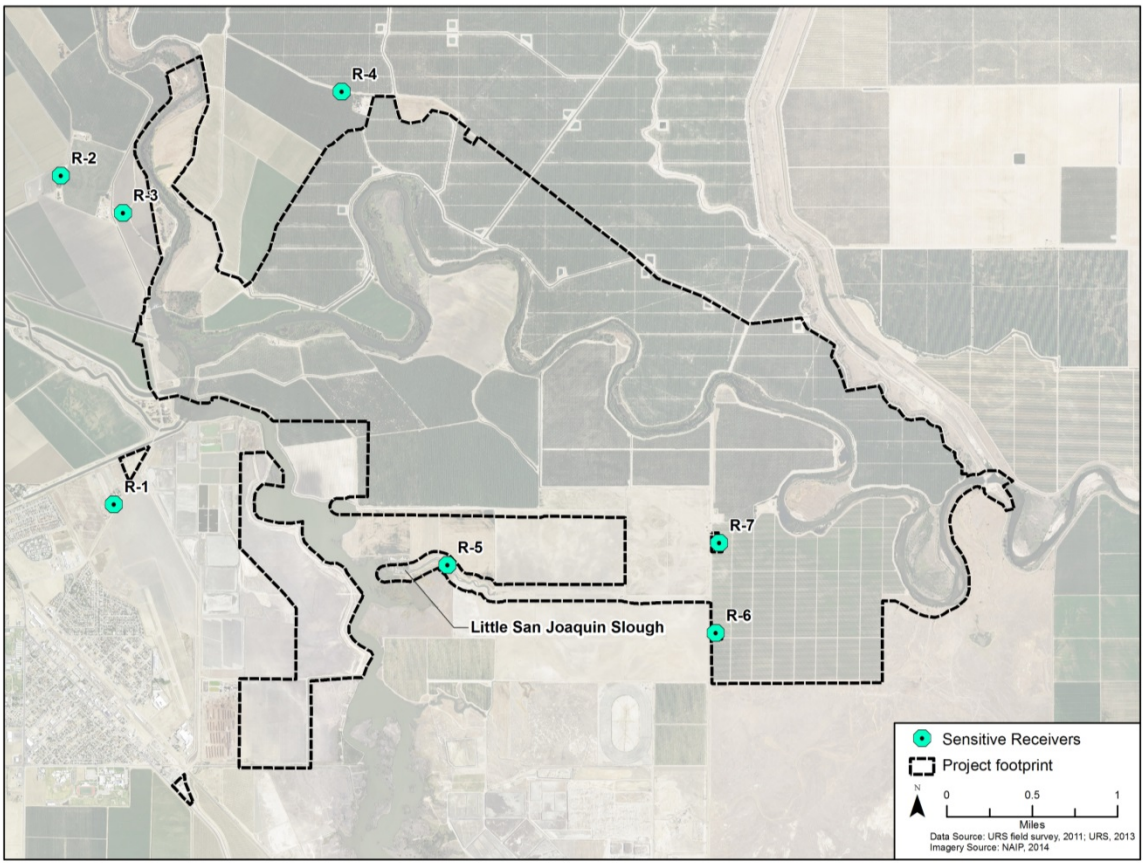

Figure 4-2.
Location of Existing Sensitive Receptors

4.2 Regulatory Setting

Air quality within the Project area and vicinity is regulated by the EPA, the ARB, the SJVAPCD, Fresno and Madera counties, and the cities of Fresno and Firebaugh. Each of these agencies develops rules, regulations, policies, and/or goals to comply with applicable legislation. Although EPA regulations may not be superseded, both State and local regulations may be more stringent.

4.2.1 Federal

Federal laws and regulations pertaining to air quality are discussed below.

Federal Clean Air Act

The Federal Clean Air Act (CAA) was enacted in 1970 to protect and enhance the Nation's air quality to promote public health and welfare and the productive capacity of the Nation's population. The CAA requires an evaluation of any Federal action to determine its potential impact on air quality in the project region. California has a corresponding law, which also must be considered during the preparation of this

Environmental Impact Statement/Report (EIS/R). Most regulatory responsibilities under the CAA are delegated to State, regional, or local government bodies.

The CAA requires areas with unhealthy levels of ozone, CO, NO_2, SO_2, and inhalable particulate matter to develop State Implementation Plans (SIPs) to comply with the national ambient air quality standards (42 United States Code [USC] §7410 et seq.). Federal agencies must conform to SIPs, meaning they must ensure that federally supported activities will not cause or contribute to a new violation, increase the severity of an existing violation, or delay timely attainment of any standard in any area (42 USC §7506(c)(1)(B)).

Proponents of specific projects must demonstrate that the actions will conform to the CAA and the SIP. A Federal action conforms with an applicable SIP if (1) the total of direct and indirect emissions from the action are compliant and consistent with the requirements of the SIP, and (2) one of a list of enumerated, pollutant-specific requirements is satisfied (such as accounting for the Federal action's projected emission of any criteria pollutant in the SIP, or offsetting ozone or NO_2 emissions within the nonattainment area) (42 Code of Federal Regulations [CFR] 93.158(a)). Ultimately, a conformity analysis may require revising a SIP, implementing mitigation measures to bring the Federal action's emissions levels down, or altering the action, possibly by reducing the magnitude of the action, to reduce emissions to levels within the budgets established by the SIP for specific pollutants.

Section 176 of the CAA prohibits Federal agencies from engaging in or supporting an action or activity that does not conform to an applicable SIP. Actions and activities must conform to a SIP's purpose of eliminating or reducing the severity and number of violations of the national ambient air quality standards, and in attaining those standards expeditiously.

Any Federal agency providing financial assistance, issuing a license or permit, or approving or supporting in any way a proposed project located in a nonattainment or maintenance area for a criteria air pollutant is required to issue a conformity analysis. The conformity analysis must certify that the federally permitted project is consistent with the SIP developed pursuant to the CAA. A conformity analysis is required unless the proposed action's emissions are below the federally established *de minimis* emissions thresholds, and the proposed action's emissions do not reach the level of 10 percent or more of the regional emissions budget for any given pollutant in the nonattainment area. This is also applicable to short-term, construction-related emissions, and therefore applies to the Project.

Criteria Air Pollutants

At the Federal level, the EPA has been charged with implementing national air quality programs. EPA's air quality mandates are drawn primarily from the CAA. The most recent major amendments made by Congress were in 1990.

The CAA required the EPA to establish national ambient air quality standards (NAAQS). As shown in Table 4-3, the EPA has established primary and secondary NAAQS for the

following criteria air pollutants: ozone, CO, NO_2, SO_2, PM_{10}, $PM_{2.5}$ and lead. The primary standards protect the public health and the secondary standards protect public welfare. The CAA also required each State to prepare an air quality control plan or SIP. The Federal Clean Air Act Amendments of 1990 (CAAA) added requirements for States with nonattainment areas to revise their SIPs to incorporate additional control measures to reduce air pollution. The SIP is modified periodically to reflect the latest emissions inventories, planning documents, and rules and regulations of the air basins as reported by their jurisdictional agencies. The EPA must review all State SIPs to determine whether they conform to the mandates of the CAA and the amendments thereof, and to determine whether implementing them would achieve air quality goals. If the EPA determines a SIP to be inadequate, a Federal Implementation Plan that imposes additional control measures may be prepared for the nonattainment area. Failure to submit an approvable SIP or to implement the plan within the mandated time frame may cause sanctions to be applied to transportation funding and stationary air pollution sources in the air basin.

Toxic Air Contaminants

The EPA has programs for identifying and regulating toxic air contaminants (HAPs in the Federal parlance). Title III of the CAAA directed the EPA to promulgate national emissions standards for HAPs. The standards may differ for major sources than for area sources of HAPs. Major sources are defined as stationary sources with potential to emit more than 10 tons per year of any HAP or more than 25 tons per year of any combination of HAPs; all other sources are considered area sources. The CAAA called on the EPA to promulgate emissions standards in two phases. In the first phase (1992–2000), the EPA developed technology-based emission standards designed to produce the maximum emission reduction achievable. These standards are generally referred to as requiring Maximum Achievable Control Technology. For area sources, the standards may be different based on generally available control technology. In the second phase (2001–2008), the EPA was required to promulgate health risk–based emissions standards where deemed necessary to address risks remaining after implementation of the technology-based national emissions standards for HAPs.

The CAAA also required the EPA to promulgate vehicle or fuel standards containing reasonable requirements that control toxic emissions including benzene and formaldehyde. Performance criteria were established to limit mobile-source emissions of toxics, including benzene, formaldehyde, and 1,3-butadiene. In addition, Section 219 of the CAAA required the use of reformulated gasoline in selected areas with the most severe ozone nonattainment conditions to further reduce mobile-source emissions.

Odors

There are no Federal laws, regulations, or policies pertaining to odors.

General Conformity

To determine whether projects are subject to the general conformity determination requirements, the EPA has established general conformity threshold values (in tons per calendar year) for each of the criteria pollutants for each type of federally designated nonattainment and maintenance areas. If the emissions generated by construction or operation of a project (on an area-wide basis) are less than these threshold values, the

General Conformity Rule is not applicable and no additional analyses are required. If the emissions are greater than these values, compliance with the General Conformity Rule must be demonstrated.

General conformity requirements apply only to federally designated maintenance and nonattainment areas. The Project area is in an area federally designated as an extreme nonattainment area for the 8-hour ozone standard, a nonattainment area for $PM_{2.5}$, and a maintenance area for PM_{10}. The applicability threshold values for this area, according to 40 CFR Part 93, are 10 tons per year for volatile organic compounds, 10 tons per year for NO_X, and 100 tons per year for $PM_{2.5}$ and PM_{10}.

As such, the Project must demonstrate compliance with the General Conformity Rule before construction begins. Compliance with the General Conformity Rule can be demonstrated in one or more of the following ways:

- By reducing construction-phase emissions to below the general conformity *de minimis* thresholds.
- By showing that the construction-phase emissions are included in the area's emission budget for the SIP.
- By demonstrating that the State agrees to include the emission increases in the area's SIP without exceeding emission budgets.
- By offsetting the Project's construction-phase emissions in each year that the thresholds are exceeded.
- Through an air quality modeling analysis demonstrating that the Project would not cause or exacerbate a NAAQS violation (however, this cannot be used for ozone precursors in ozone nonattainment areas).

4.2.2 State of California

State laws and regulations pertaining to air quality are discussed below.

California Clean Air Act

The California Clean Air Act (CCAA) of 1988 requires nonattainment areas, such as the SJVAB, to achieve and maintain State ambient air quality standards by the earliest practicable date. The CCAA also requires local air districts to develop plans for attaining State ozone, CO, NO_2, and SO_2 standards. The SJVAPCD has the authority to issue permits and ensure compliance with air quality regulations in the Project area.

The SJVAPCD is required by the CCAA to develop "indirect source" control programs in its attainment plans. The SJVAPCD is committed to reducing PM_{10} and nitrous oxides (N_2O) emissions from indirect sources in the 2003 PM_{10} Plan and the 2004 Extreme Ozone Attainment Demonstration Plan. The SJVAPCD's Governing Board adopted District Rule 9510 as a result of this commitment. In accordance with SJVAPCD Rule 9510, Indirect Source Review, applicants must mitigate project impacts through the incorporation of on-site emission reducing design elements and/or the payment of fees that would be used to fund off-site emissions reduction projects.

In accordance with SJVAPCD Rule 8021 – Construction, Demolition, Excavation, Extraction, and Other Earthmoving Activities, the owner or operator of a construction project is required to submit a Dust Control Plan to the SJVAPCD if at any time the project would involve:

- Residential developments of 10 or more acres of disturbed surface area.
- Nonresidential developments of 5 or more acres of disturbed surface area.
- Moving, depositing, or relocating of more than 2,500 cubic yards per day of bulk materials on at least three days of the project.

A Dust Control Plan identifies the fugitive dust sources at the construction site and describes all of the dust control measures to be implemented before, during, and after any dust-generating activity for the duration of the project. The owner or operator is required to comply with all requirements of the applicable rules under Regulation VIII and the SJVAPCD's Rules and Regulations at all times.

Criteria Air Pollutants

The ARB is the agency responsible for coordination and oversight of State and local air pollution control programs in California and for implementing the CCAA. The CCAA, which was adopted in 1988, required the ARB to establish California ambient air quality standards (CAAQS) (Table 4-3). The ARB has established CAAQS for sulfates, hydrogen sulfide, vinyl chloride, visibility-reducing particulate matter, and the above-mentioned criteria air pollutants. In most cases the CAAQS are more stringent than the NAAQS. Differences in the standards are generally explained by the health effects studies considered during the standard-setting process and the interpretation of the studies. In addition, the CAAQS incorporate a margin of safety to protect sensitive individuals.

The CCAA requires that all local air districts in the State endeavor to achieve and maintain the CAAQS by the earliest practical date. The act specifies that local air districts should focus particular attention on reducing the emissions from transportation and area-wide emission sources, and provides districts with the authority to regulate indirect sources.

Among the ARB's other responsibilities are overseeing local air district compliance with California and Federal laws, approving local air quality plans, submitting SIPs to the EPA, monitoring air quality, determining and updating area designations and maps, and setting emissions standards for new mobile sources, consumer products, small utility engines, off-road vehicles, and fuels. In California, there are 15 nonattainment areas for the national ozone standard and two nonattainment areas for the $PM_{2.5}$ standard (EPA 2013d). The ozone SIP and $PM_{2.5}$ SIP were adopted and sent to the EPA on 2007 and 2012, respectively. The SIP must show how each area would attain the Federal standards. To do this, the SIP identifies the amount of pollution emissions that must be reduced in each area to meet the standard and the emission controls needed to reduce the necessary emissions.

Toxic Air Contaminants

Toxic air contaminants in California are primarily regulated through the Tanner Air Toxics Act (Assembly Bill [AB] 1807) and the Air Toxics Hot Spots Information and Assessment Act of 1987 (AB 2588). AB 1807 sets forth a formal procedure for the ARB to designate substances as toxic air contaminants. Research, public participation, and scientific peer review must occur before the ARB can designate a substance as a toxic air contaminant. To date, the ARB has identified more than 21 toxic air contaminants and adopted the EPA's list of HAPs as toxic air contaminants. Most recently, diesel particulate matter was added to the ARB list of toxic air contaminants.

Once a toxic air contaminant is identified, the ARB then adopts an Airborne Toxics Control Measure for sources that emit that particular toxic air contaminant. If there is a safe threshold for a substance at which there is no toxic effect, the control measure must reduce exposure below that threshold. If there is no safe threshold, the measure must incorporate best available control technology (BACT) to minimize emissions (e.g., the airborne toxics control measure limits truck idling to 5 minutes [Cal. Code Regs., tit. 13, Ch. 10, § 2485]).

The Hot Spots Act requires that existing facilities that emit toxic substances above a specified level prepare a toxic-emission inventory, prepare a risk assessment if emissions are significant, notify the public of significant risk levels, and prepare and implement risk reduction measures.

The ARB has adopted diesel-exhaust control measures and more stringent emission standards for various on-road mobile sources of emissions, including transit buses and off-road diesel equipment (e.g., tractors, generators). In February 2000, the ARB adopted a new public-transit bus fleet rule and emission standards for new urban buses. These new rules and standards provide for (1) more stringent emission standards for some new urban bus engines, beginning with 2002 model year engines; (2) zero-emission bus demonstration and purchase requirements applicable to transit agencies; and (3) reporting requirements, under which transit agencies must demonstrate compliance with the public-transit bus fleet rule. Current milestones include the low-sulfur diesel fuel requirement and tighter emission standards for heavy-duty diesel trucks (2007) and off-road diesel equipment (2011) nationwide. Over time, the replacement of older vehicles would result in a vehicle fleet that produces substantially lower levels of toxic air contaminants than under current conditions. Mobile-source emissions of toxic air contaminants (e.g., benzene, 1,3-butadiene, diesel particulate matter) have been reduced significantly over the last decade, and would be reduced further in California through a progression of regulatory measures (e.g., Low Emission Vehicle/Clean Fuels and Phase II reformulated gasoline regulations) and control technologies. With implementation of ARB's Risk Reduction Plan, it is expected that diesel particulate matter concentrations would be reduced by 85 percent in 2020 from the estimated year-2000 level. Adopted regulations are also expected to continue to reduce formaldehyde emissions from cars and light-duty trucks. As emissions are reduced, it is expected that risks associated with exposure to the emissions would also be reduced.

The ARB (2005) published the *Air Quality and Land Use Handbook: A Community Health Perspective,* which provides guidance concerning land use compatibility with toxic air contaminant sources. While not a law or adopted policy, the handbook offers advisory recommendations for the siting of sensitive receptors near uses associated with toxic air contaminants, such as freeways and high-traffic roads, commercial distribution centers, rail yards, ports, refineries dry cleaners, gasoline stations, and industrial facilities.

Odors

There are no State laws, regulations, or policies pertaining to odors.

4.2.3 Regional and Local

Regional and local plans and policies pertaining to air quality are discussed below. The Project area is located within the SJVAB which is regulated by the SJVAPCD.

Criteria Air Pollutants

San Joaquin Valley Air Pollution Control District Regulations

The SJVAPCD seeks to improve air quality conditions in the SJVAB through a comprehensive program of planning, regulation, enforcement, technical innovation and promotion of the understanding of air quality issues. The clean air strategy of the SJVAPCD includes preparing plans and programs for the attainment of ambient air quality standards (AAQS), adopting and enforcing rules and regulations, and issuing permits for stationary sources. The SJVAPCD also inspects stationary sources, responds to citizen complaints, monitors ambient air quality and meteorological conditions, and implements other programs and regulations required by the CAA, CAAA, and CCAA.

Guide for Assessing and Mitigating Air Quality Impacts. In January 2002, the SJVAPCD released a revision to the previously adopted guidelines document. This revised *Guide for Assessing and Mitigating Air Quality Impacts* (GAMAQI) (SJVAPCD 2002) is an advisory document that provides lead agencies, consultants, and project applicants with uniform procedures for addressing air quality in environmental documents. The guide contains the following applicable components:

- Criteria and thresholds for determining whether a project may have a significant adverse air quality impact.
- Specific procedures and modeling protocols for quantifying and analyzing air quality impacts.
- Methods available to mitigate air quality impacts.
- Information for use in air quality assessments that is updated frequently such as air quality data, regulatory setting, climate and topography.

The SJVAPCD prepared an updated Draft GAMAQI in 2012 and a subsequent update to the Draft GAMAQI in July 2014. The Draft 2012 GAMAQI and 2014 GAMAQI contain similar thresholds of significance with additional clarification on criteria mass emissions. They also update and clarify the methodologies and basis for thresholds.

Air Quality Attainment Plans. The SJVAPCD prepares and submits Air Quality Attainment Plans in compliance with the requirements set forth in the CCAA. The CCAA also requires a triennial assessment of the extent of air quality improvements and emission reductions achieved through the use of control measures. As part of the assessment, the attainment plans must be reviewed and, if necessary, revised to correct for deficiencies in progress and to incorporate new data or projections. As a nonattainment area, the region is also required to submit rate-of-progress milestone evaluations in accordance with the CAAA. These milestone reports include compliance demonstrations if requirements are being met in the nonattainment area. The air quality attainment plans and reports present comprehensive strategies to reduce emissions of ROG, NO_X, and $PM_{10}/PM_{2.5}$ from stationary, area, mobile and indirect sources. Such strategies include the adoption of rules and regulations; enhancement of California Environmental Quality Act (CEQA) participation; implementation of a new and modified indirect-source review program; adoption of local air quality plans; and stationary-, mobile-, and indirect-source control measures. Table 4-4 summarizes the SJVAPCD's current Air Quality Attainment Plans.

Rules and Regulations. As mentioned above, the SJVAPCD adopts rules and regulations. All projects are subject to the SJVAPCD's rules and regulations in effect at the time of construction. Specific rules applicable to the construction of the Project may include, but are not limited to:

Regulation VIII—Fugitive Dust PM_{10} Prohibitions: Rules 8011 to 8081 are designed to reduce PM_{10} emissions (predominantly dust/dirt) generated by human activity, including construction and demolition activities, road construction, bulk materials storage, paved and unpaved roads, carryout and track out, and landfill operations. Compliance with Regulation VIII is mandatory. If a nonresidential project is 5 or more acres in area, a Dust Control Plan must be submitted as specified in Section 6.3.1 of Rule 8021 and construction activities are not allowed to commence until the SJVAPCD has approved the plan.

Rule 2010—Permits Required: This rule applies to any person who plans to or does operate, construct, alter, or replace any source operation which may emit air contaminants or may reduce the emission of air contaminants. This Project, or portions thereof, may be subject to SJVAPCD permitting requirements.

Rule 2201—New and Modified Stationary Source Review Rule: This rule applies to all new stationary sources and all modifications of existing stationary sources. They are subject to SJVAPCD permit requirements if, after construction, they emit or may emit one or more affected pollutant.

Rule 3135—Dust Control Plan Fee: This rule requires the applicant to submit a fee in addition to a Dust Control Plan. The purpose of this fee is to recover the SJVAPCD's cost for reviewing such plans and conducting compliance inspections.

Table 4-4.
Summary of San Joaquin Valley Air Pollution Control District Air Quality Plans

Pollutant	Plan Title	Date	Status
Ozone	*Extreme Ozone Attainment Demonstration Plan, San Joaquin Valley Air Basin Plan Demonstrating Attainment of Federal 1-Hour Ozone Standards*	October 2004, Amended October 2005	Adopted by SJVAPCD and ARB in October 2004. Submitted to EPA in November 2004.[1]
	2013 Plan for the Revoked 1-Hour Ozone Standard	September 2013	Adopted by SJVAPCD on September 19, 2013.
	Draft Staff Report, 8-Hour Ozone Reasonably Available Control Technology—State Implementation Plan Analysis	April 2006	Adopted by SJVAPCD in August 17, 2006.
	8-Hour Ozone Attainment Demonstration Plan for the San Joaquin Valley	April 2007	Adopted by SJVAPCD in April 2007. Approved by ARB in June 2007. EPA approved the SJVAPCD 8-hour plan (revised in 2008 and 2011) on March 1, 2012
Carbon Monoxide (CO)	*2004 Revision to the California State Implementation Plan for Carbon Monoxide Updated Maintenance Plan for the Federal Planning Areas*	July 2004	Adopted by ARB July 2004. Approved by EPA on November 30, 2005
Respirable and Fine Particulate Matter (PM_{10} and $PM_{2.5}$)	*$PM_{2.5}$ Plan*	December 2012	Adopted by SJVAPCD in December 2012. Adopted by ARB January 2013 and submitted to the EPA.
	Natural Events Action Plan for High Wind Events in the San Joaquin Valley	August 2008	Adopted by SJVAPCD August 2008. Final Version submitted to ARB and EPA on August 7, 2008.

ARB = California Air Resources Board

EPA = U.S. Environmental Protection Agency

SJVAPCD = San Joaquin Valley Air Pollution Control District

Rule 4101—Visible Emissions: This rule prohibits emissions of visible air contaminants to the atmosphere and applies to any source operation that emits or may emit air contaminants.

Rule 4102—Nuisance: This rule applies to any source operation that emits or may emit air contaminants or other materials. In the event that such emissions create a public nuisance, the owner/operator could be in violation and be subject to SJVAPCD enforcement action.

Rule 4601—Architectural Coatings: This rule limits volatile organic compounds from architectural coatings by specifying architectural coatings storage, clean up, and labeling requirements.

Rule 4641—Cutback, Slow Cure, and Emulsified Asphalt, Paving and Maintenance Operations: This rule applies to the manufacture and use of the aforementioned asphalt types for paving and maintenance operations.

Rule 9510—Indirect Source Review: This rule was adopted to reduce the impacts of growth in emissions from all new development in the SJVAB. The purposes of Rule 9510 are to (1) fulfill the SJVAPCD's emission reduction commitments in the PM_{10} and Ozone Attainment Plans; (2) achieve emission reductions from the construction and use of development projects through design features and on-site measures; and (3) provide a mechanism for reducing emissions from the construction of and use of development projects through off-site measures.

The rule is applicable to any person or entity that undertakes a development project, which upon full build out is 2,000 square feet or more of retail/commercial uses, or 9,000 square feet or more of space not identified in Rule 9510, or any transportation or transit project where construction exhaust emissions equal or exceed 2 tons of NO_X or 2 tons of PM_{10}. As such, this rule is applicable to the San Joaquin River Restoration Program (SJRRP) because projects implemented under the SJRRP meet these criteria. Compliance with Rule 9510 would be required.

Fresno County General Plan

Section G, Air Quality, of the Open Space and Conservation Element of the Fresno County General Plan states that the County would support and implement SJVAPCD programs in maintaining air quality within the County and that the County would consider all air quality implications for new discretionary land use development and transportation infrastructure improvements (Policies OS-G.1 through OS-G.16) (Fresno County 2000).

Madera County General Plan

In 2010 Madera County adopted an Air Quality Element to its General Plan. The Air Quality Element states that the County would support and implement SJVAPCD programs in maintaining air quality within the County and that the County would integrate air quality planning into the transportation planning process (Madera County 2010).

City of Fresno General Plan

Section G-1, Air Quality, of the Resource Conservation Element includes the objective to, in cooperation with other jurisdictions and agencies in the SJVAB, take necessary actions to achieve and maintain compliance with State and national air quality standards (City of Fresno 2009).

City of Firebaugh

The city of Firebaugh does not currently have a general plan or any air quality regulations in its municipal code.

City of Mendota

The city of Mendota General Plan Update 2002-2005 states that the City would support and implement SJVAPCD programs in maintaining air quality within the City and that the City would integrate air quality planning into the transportation planning process. Policies are in support of land use designs to encourage infill and density to support pedestrian circulation which would decrease use of mobile sources. Policies are in support of energy efficient to reduce energy consumption. Policies are in support of construction equipment control devices when operating near sensitive receptors to control the diesel exhaust particulate matter (City of Mendota 2009).

Toxic Air Contaminants

At the local level, air pollution control or management districts may adopt and enforce ARB control measures. Under SJVAPCD Regulations II and VII, all sources that possess the potential to emit toxic air contaminants are required to obtain permits from the district. Permits may be granted to these operations if they are constructed and operated in accordance with applicable regulations, including new-source review standards and air toxics control measures. The SJVAPCD limits emissions and public exposure to toxic air contaminants through a number of programs. The SJVAPCD prioritizes toxic air contaminant-emitting stationary sources based on the quantity and toxicity of the toxic air contaminant emissions and the proximity of the facilities to sensitive receptors.

Projects that require a permit are analyzed by the SJVAPCD (e.g., health risk assessment) on the basis of their potential to emit toxics. If it is determined that the project would emit toxics in excess of the SJVAPCD's threshold of significance for toxic air contaminants, as identified below, projects must implement the best available control technology for toxic air contaminants (T-BACT) to reduce emissions. If a project cannot reduce the risk below the threshold of significance, even after T-BACT has been implemented, the SJVAPCD would deny the permit required by the project. This helps to prevent new problems and reduces emissions from existing older sources by requiring them to apply new technology when retrofitting with respect to toxic air contaminants. It is important to note that the SJVAPCD's air quality permitting process applies to stationary sources; properties that are exposed to elevated levels of non-stationary type sources of toxic air contaminants, and the non-stationary type sources themselves (e.g., on-road vehicles), are not subject to air quality permits. Further, for reasons of feasibility and practicality, mobile sources (e.g., cars, trucks) are not required to implement T-BACT, even if they do have the potential to expose adjacent properties to elevated levels of toxic air contaminants. Rather, emissions controls on such sources (e.g., vehicles) are subject to regulations implemented on the Federal and State levels.

Odors

The SJVAPCD has determined some common types of facilities that have been known to produce odors, including wastewater treatment facilities, chemical manufacturing plants, painting/coating operations, feed lots/dairies, composting facilities, landfills and transfer stations. Any actions related to odors are based on citizen complaints to local governments and the SJVAPCD. According to the SJVAPCD, significant odor problems occur when there is more than one confirmed complaint per year averaged over a three-

year period or when there are three unconfirmed complaints per year averaged over a three-year period (SJVAPCD 2002).

Two situations increase the potential for odor problems. The first occurs when a new odor source is located near existing sensitive receptors. The second occurs when new sensitive receptors are developed near existing sources of odor. In the first situation, the SJVAPCD recommends operational changes, add-on controls, process changes or buffer zones where feasible to address odor complaints. In the second situation, the potential conflict is considered significant if the project site is at least as close as any other site that has already experienced significant odor problems related to the odor source. For projects locating near a source of odors where there is no nearby development that may have filed complaints, and for odor sources locating near existing sensitive receptors, the SJVAPCD requires the determination of potential conflict to be based on the distance and frequency at which odor complaints from the public have occurred in the vicinity of a similar facility (SJVAPCD 2002). The SJVAPCD has adopted Rule 4102, as identified above, that applies to odor emissions.

4.3 Environmental Consequences and Mitigation Measures

4.3.1 Impact Assessment Methodology

This section addresses the potential for impacts to air quality and human health.

Construction activities associated with the Project would generate criteria air pollutant emissions: CO, SO_2, particulate matter (PM_{10} and $PM_{2.5}$); and ozone precursors (ROGs and NO_x). Construction of the Project would generate toxic air contaminant emissions: diesel particulate matter and gasoline related toxic air contaminants.

The following approach was used to estimate criteria pollutant emissions. Exhaust emissions from off-road construction equipment were estimated using the Roadway Construction Emissions Model (RoadMod) and In-Use Off-road Equipment 2011 Inventory Model[1] (Sacramento Metropolitan Air Quality Management District 2012). On-road mobile source emissions from worker and truck trips was calculated using estimates of vehicle miles traveled and appropriate emission factors from Emission Factors Modeling Software (EMFAC) (ARB 2007b). Fugitive dust from earthmoving activities was quantified using AP-42 emission factors. Fugitive dust emissions from mobile source trips and stockpiling was estimated using AP-42 Chapter 13.2 emission factors.

In addition, potential health risks from toxic air contaminants to nearby sensitive receptors (e.g., local parks, residential areas, and schools) were evaluated based on California Office of Environmental Health Hazard Assessment's (OEHHA's) guidelines (OEHHA 2012). Sensitive receptors are populations that are susceptible to the effects of exposure to air toxics such as children and elderly people. Heavy-duty diesel trucks are a

[1] This replaces OFFROAD2007 for construction and mining equipment.

source of diesel particulate matter, which is classified as a chronic and carcinogenic health risk.

Construction Emission Estimation

The construction emissions were broken down into three categories: off-road equipment exhaust, fugitive dust emissions from construction activities, and on-road mobile source exhaust emissions. Emissions were estimated using emission factors taken from RoadMod which has been updated to incorporate the emission factors from In-Use Off-road Equipment 2011 Inventory Model for the off-road equipment (ARB 2011e). The emission factors for on-road mobile sources are based on EMFAC for the SJVAPCD for calendar year 2014 (ARB 2007b). The fugitive dust emissions from construction equipment and travel on roads are based on AP-42 emission factors. Further details on the specific emission factors used are provided in Appendix 4-A – Tables.

The California Department of Water Resources (DWR) provided construction schedules and equipment lists that were used to determine the number, size, and duration of construction equipment activity.[2] A summary of this information is provided in Appendix 4-A – Tables. Project assumptions include: a constant of 100 workers would be used throughout the Project duration; there would be on average 18 working days per month; workers would travel 35 miles each one-way trip; and material hauling trips would average 135 miles for each one-way trip. The number of material hauling trips and the duration of equipment use varies by alternative based on the type of construction activity, as detailed in Appendix 4-A– Tables. Assumptions were based on information provided by DWR and are consistent with those detailed in the Traffic Analysis in Chapter 22.0.

Fugitive dust occurs from various types of construction activity associated with site preparation, grading, dozing, and loading/unloading material. The EPA's AP-42 emission factors for Western Surface Coal Mining were used to estimate the emissions from fugitive dust from grading, bulldozing, and material loading and unloading (EPA 1998). On-road mobile sources generate fugitive dust when traveling on paved and unpaved roads. These were estimated using the EPA's AP-42 emission factors for Paved and Unpaved Roads (EPA 2006, 2011a). Details of these calculations are in Appendix 4-A – Tables.

Operational Emission Estimation

The operational emissions are associated with vehicle traffic of workers to provide maintenance and operation of the Project. The trips were provided by the DWR and other assumptions detailed in the Traffic Analysis. The workers were assumed to travel 35 miles each one-way trip.

The emission factors for on-road mobile sources are conservatively based on EMFAC for the SJVAPCD for calendar year 2014 (ARB 2007b). The fugitive dust emissions travel on roads is based on AP-42 emission factors. Further details on the specific emission factors used are provided in Appendix 4-A – Tables.

[2] If phase duration was not specified, 18 days was assumed.

Health Risk Assessment

The construction equipment and material hauling vehicles emit diesel particulate matter that is classified as a toxic air contaminant. Gasoline-fueled vehicles emit various toxic air contaminants in much smaller quantities and health toxicity compared to diesel particulate matter. Thus, gasoline fueled emission sources have not been included further in this health risk assessment. The emissions of diesel particulate matter sources are used in the health risk assessment and the details of the emission rates used are contained in Appendix 4-A – Tables.

In order to evaluate the impacts of diesel particulate matter on nearby sensitive receptors, a health risk assessment was conducted consistent with OEHHA (OEHHA 2003, 2012) and SJVAPCD guidelines (SJVAPCD 2006) for determining local community risks and hazards. The health risk assessment evaluated the health risks associated with the Project emissions from construction equipment and material hauling vehicles. The detailed information on the methodology and data used to conduct the health risk assessment since air dispersion modeling was required is summarized in Appendix 4-B – Health Risk Assessment Methodology.

4.3.2 Significance Criteria

The Project was evaluated in accordance with the Air Quality section of Appendix G of the CEQA Environmental Checklist and professional judgment on anticipated impacts on air quality. Under the National Environmental Policy Act (NEPA) Council on Environmental Quality (CEQ) Regulations, effects must be evaluated in terms of their context and intensity. These factors have been considered when applying the CEQA Guidelines Appendix G. The Project would result in a significant impact on air quality if it would do any of the following:

- Conflict with or obstruct implementation of the applicable air quality plan.
- Violate any air quality standard or contribute substantially to an existing or projected air quality violation.
- Result in a cumulatively considerable net increase of any criteria pollutant for which the Project region is non-attainment under an applicable Federal or State ambient air quality standard (including releasing emissions which exceed quantitative thresholds for ozone precursors).
- Expose sensitive receptors to substantial pollutant concentrations.
- Create objectionable odors affecting a substantial number of people.

The regional criteria pollutant emissions were compared to the SJVAPCD significance thresholds to determine CEQA significance and to the General Conformity Rule *de minimis* thresholds to determine NEPA effects. These thresholds are shown in Table 4-5. If emissions exceed the SJVAPCD significance thresholds, the emissions would have to be mitigated in order for the impacts to be considered less than significant. If emissions exceed the General Conformity Rule *de minimis* thresholds, a general conformity analysis would be required. Construction emissions are compared to these significance thresholds

to determine significance impacts. Operational emissions for criteria pollutants are also compared to these significance thresholds.

The health risk analysis used the OEHHA's guidance to estimate the Project's incremental increase in chronic and cancer health risks to nearby sensitive receptors. The OEHHA's guidance provides procedures for determining chronic and cancer risk. It provides guidance on exposure parameters such as breathing rates and provides guidance on how to use the tiered approach to analyze health risk impacts.

The significance threshold for health impacts to sensitive receptors is an incremental increase in cancer risk greater than 10 in a million or an chronic hazard index greater than 1 (SJVAPCD 2002, 2012, 2014).

Table 4-5.
SJVAPCD CEQA and General Conformity Rule *de minimis* Thresholds of Significance

Pollutant	SJVAPCD CEQA Thresholds (tpy)	GCR *de minimis* thresholds (tpy)
Ozone precursor (NO_x)	10	10
Ozone precursor (ROGs)	10	10
Carbon monoxide (CO)	100	N/A
Sulfur oxides (SO_x)	27	N/A
Fine Particulate Matter ($PM_{2.5}$)	15	100
$PM_{2.5}$ precursor (SO_2)	N/A	100
Respirable Particulate Matter (PM_{10})	15	100

tpy = tons per year

4.3.3 Impacts and Mitigation Measures

This section provides a Project-level evaluation of direct and indirect effects of the Project alternatives on air quality. It includes analyses of potential effects relative to No-Action conditions in accordance with NEPA and potential impacts compared to existing conditions to meet CEQA requirements. The analysis is organized by Project alternative with specific impact topics numbered sequentially under each alternative. With respect to air quality, the environmental impact issues and concerns are the potential to:

1. Create Excess Amounts of Construction Related Criteria Air Pollutants that Exceed SJVAPCD Thresholds of Significance or Cause or Contribute to Exceedances of the AAQS.
2. Conflict with Applicable Plans or Policies Related to Air Quality.

3. Expose Sensitive Receptors to Substantial Air Pollutants Associated with Construction.
4. Create Excess Amounts of Operational Related Criteria Air Pollutants that Exceed SJVAPCD Thresholds of Significance or Cause or Contribute to Exceedances of the AAQS.
5. Expose Sensitive Receptors to Substantial Air Pollutants Associated with Operation.
6. Create Objectionable Odors from Construction.
7. Create Objectionable Odors from Operation.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. However, other proposed actions under the SJRRP would be implemented, including habitat restoration, augmentation of river flows, and reintroduction of salmon. Without the Project in Reach 2B, however, these Program-level activities would not achieve Settlement goals. This section describes the impacts of the No-Action Alternative. The analysis is a comparison to existing conditions, and no mitigation is required for No-Action.

Impact AQ-1 (No-Action Alternative*): Create Excess Amounts of Construction Related Criteria Air Pollutants that Exceed SJVAPCD Thresholds of Significance or Cause or Contribute to Exceedances of the AAQS*. Under the No-Action Alternative, the Project would not be implemented and there would be no associated construction activities in the Project area. Therefore, there would be no Project-related construction related criteria air pollutants. As a result, there would be **no impact** on air quality from Project-related construction emissions.

Impact AQ-2 (No-Action Alternative): *Conflict with Applicable Plans or Policies Related to Air Quality*. Under the No-Action Alternative, the Project would not be implemented and there would be no associated construction activities in the Project area. In addition, there would be no change in any sources of operational related emissions in the Project area. This includes any emissions associated with vehicles traveling to the Project area for operation and maintenance of the existing facilities located in the Project area. The SJVAPCD has several plans and policies relating to air emissions in the SJVAB. These specifically address ozone, PM_{10} and $PM_{2.5}$ as these are designated as non-attainment under the State and national AAQS. The No-Action Alternative would not generate any new sources of emissions for construction or operation nor does the existing setting have any significant sources of emissions that would be targeted for reduction by the plans and policies. Therefore, there would be no conflicts with applicable plans or policies related to air quality and this would have **no impact**.

Impact AQ-3 (No-Action Alternative): *Expose Sensitive Receptors to Substantial Air Pollutants Associated with Construction*. Under the No-Action Alternative, the Project would not be implemented and there would be no associated construction activities in the

Project area. Therefore, there would be no construction related toxic air contaminants. As a result, there would be **no impact** on sensitive receptors due to toxic air contaminants.

Impact AQ-4 (No-Action Alternative): ***Create Excess Amounts of Operational Related Criteria Air Pollutants that Exceed SJVAPCD Thresholds of Significance or Cause or Contribute to Exceedances of the AAQS***. Under the No-Action Alternative, the Project would not be implemented and there would be no Project-related operational activities in the Project area. Therefore, there would be no operational related criteria air pollutants. As a result, there would be **no impact** on air quality from operational emissions.

Impact AQ-5 (No-Action Alternative): ***Expose Sensitive Receptors to Substantial Air Pollutants Associated with Operation***. Under the No-Action Alternative, the Project would not be implemented and there would be no Project-related operational activities in the Project area. Therefore, there would be no operational related toxic air contaminants. As a result, there would be **no impact** on sensitive receptors due to toxic air contaminants.

Impact AQ-6 (No-Action Alternative): ***Create Objectionable Odors from Construction.*** Under the No-Action Alternative, the Project would not be implemented and there would be no construction activities in the Project area. Therefore, there would be no construction related odors. As a result, there would be **no impact** from odors.

Impact AQ-7 (No-Action Alternative): ***Create Objectionable Odors from Operation*****.** Under the No-Action Alternative, the Project would not be implemented and there would be no Project-related operational activities in the Project area. Therefore, there would be no operational related odors. There are no existing sources of odors in the Project area. As a result; there would be **no impact** from odors.

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

Alternative A would include construction of Project facilities including a Compact Bypass channel, a new levee system with a narrow floodplain encompassing the river channel, and the South Canal. Other key features include construction of the Mendota Pool Dike (separating the San Joaquin River and Mendota Pool), a fish barrier below Mendota Dam, and the South Canal bifurcation structure and fish passage facility, modification of the San Mateo Avenue crossing, and the removal of the San Joaquin River control structure of the Chowchilla Bifurcation Structure. Construction activity is expected to occur intermittently over an approximate 132-month timeframe.

Impact AQ-1 (Alternative A)*: Create Excess Amounts of Construction Related Criteria Air Pollutants that Exceed SJVAPCD Thresholds of Significance or Cause or Contribute to Exceedances of the AAQS*. Compared to No-Action, Alternative A would implement the Project and there would be short-term construction activities in the Project area. Construction emissions were estimated for the off-road construction equipment, material hauling vehicles, worker commute vehicles, and fugitive dust emissions from construction and travel on roads (Table 4-6). The construction emissions represent the worst-case scenario where none of the borrow materials would be sourced locally and

materials would be hauled from more than 100 miles away. These construction emissions were compared to the General Conformity Rule *de minimis* thresholds for NEPA. The General Conformity Rule *de minimis* threshold would be exceeded for NOx and ROG and therefore construction emissions would be substantial.

Total construction emissions were compared to the SJVAPCD's significance thresholds for CEQA. CO, NOx, ROG, PM_{10}, and $PM_{2.5}$ criteria pollutants are above the SJVAPCD annual emissions thresholds which indicate that the Project could cause a significant impact compared to existing conditions. The CO, PM_{10}, and $PM_{2.5}$ emissions were modeled using air dispersion modeling to determine if the concentration including background was below the AAQS or below a significant impact level in the local area. NOx and ROG emissions were not modeled, as these are ozone precursors and contribute to the regional ozone problem.

The modeled 1-hour CO maximum concentration from Project sources is shown in Table 4-7. This was combined with the background concentration based on the average 1-hour concentration for 2010 to 2013. This indicates that at the point of maximum impact, the CO concentration is less than the AAQS. Therefore, modeling indicates that the Project has a less than significant impact for CO.

When modeled, the PM_{10} and $PM_{2.5}$ maximum concentrations from Project sources are shown in Table 4-8. Since the SJVAB is already in non-attainment for both PM_{10} and $PM_{2.5}$, a concentration above the significant impact level would contribute to exceedances of the AAQS. The significant impact levels are based on the Prevention of Significant Deterioration thresholds set by the SJVAPCD. The Fugitive PM_{10} annual significant impact level is 2.08 $\mu g/m^3$. The EPA vacated the $PM_{2.5}$ and Fugitive $PM_{2.5}$ annual significant impact level in 2013. As there is no adopted $PM_{2.5}$ significant impact level, the SJVAPCD recommends using the corresponding PM_{10} significant impact level for both PM_{10} and $PM_{2.5}$ analyses (Villalvazo, pers. comm., 2014). Therefore, 2.08 $\mu g/m^3$ is used as the Fugitive $PM_{2.5}$ annual significant impact level. As shown in Table 4-8 the PM_{10} and $PM_{2.5}$ Project concentrations are below this significance level. Therefore, after modeling, the construction emissions of PM_{10} and $PM_{2.5}$ are less than significant impacts. The calculated fugitive dust emissions would be further reduced if control measures from compliance with SJVAPCD Regulation VIII were quantified; as such, the fugitive dust emissions stated here are conservative because these control measures would be required through mandatory compliance with SJVAPCD Regulation VIII. Compliance with SJVAPCD Regulation VIII would reduce PM_{10} emissions (predominantly dust/dirt) generated by human activity, including construction and demolition activities, road construction, bulk materials storage, paved and unpaved roads, carryout and track out, and landfill operations.

As discussed above, NOx and ROG are above the SJVAPCD annual emissions thresholds for regional air quality. Therefore, Alternative A would have a **significant** impact for construction-related criteria air pollutants for NOx and ROG.

Key:

$\mu g/m^3$ = micrograms per cubic meter

Mitigation Measure AQ-1A (Alternative A): ***Reduce Criteria Exhaust Emissions from Construction Equipment.*** This mitigation measure will apply to heavy-duty construction equipment used during the construction phase of the Project. All off-road construction diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices (e.g., diesel particulate filters), but in no case less clean than the average fleet mix as set forth in the ARB's latest Off-road Construction Emission Database. The contractor will document efforts it undertook to locate newer equipment (Tier 4, Tier 3, or Tier 2), alternative fueled equipment (electric, compressed natural gas, or gasoline), and addition of after-market control devices. This will be documented as part of compliance with the SJVAPCD's Indirect Source Review (ISR). The mitigation would reduce criteria exhaust emissions from construction equipment.

Implementation Action: For off-road construction diesel equipment, the contractor will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices (e.g., diesel particulate filters), but in no case less clean than the average fleet mix as set forth in the ARB's latest Off-road Construction Emission Database. The contractor will document efforts it undertook to locate newer equipment (Tier 4, Tier 3, or Tier 2), alternative fueled equipment (electric, compressed natural gas, or gasoline), and addition of after-market control devices.

Location: The mitigation will apply to all construction areas.

Effectiveness Criteria: Effectiveness will be based on the emissions calculated based on actual equipment used and operating hours with a minimum performance criteria equal to the average fleet mix as set forth in the ARB's latest Off-road Construction Emission Database. This will be detailed in the Air Impact Assessment and Monitoring and Reporting Schedule submitted to the SJVAPCD in conjunction with ISR Rule 9510.

Responsible Agency: U.S. Department of the Interior, Bureau of Reclamation (Reclamation) and California State Lands Commission (CSLC).

Monitoring/Reporting Action: Adequacy of the proposed practices will be confirmed with Reclamation construction managers and CSLC monitors as detailed in the Monitoring and Reporting Schedule submitted to the SJVAPCD. The SJVAPCD would prepare a Monitoring and Reporting Schedule Compliance letter upon completion.

Timing: Mitigation will be ongoing over the construction timeframe.

Mitigation Measure AQ-1B (Alternative A): ***Reduce Criteria Exhaust Emissions from Material Hauling Vehicles.*** This mitigation measure will apply to material hauling vehicles used during the construction phase of the Project. Material hauling trips will be consolidated into the fewest trips possible. All material-hauling diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or

addition of after-market control devices (e.g., diesel particulate filters), but in no case less clean than the average fleet mix as set forth in the ARB's latest EMFAC emission database to any vehicle used that the contractor has control over (ARB 2007b). The contractor will document efforts it undertook to locate newer equipment, alternative fueled equipment (electric, compressed natural gas, or gasoline), and addition of after-market control devices. This will be documented as part of compliance with the SJVAPCD's ISR. The mitigation would reduce criteria exhaust emissions from material hauling vehicles.

Implementation Action: For material hauling vehicles, the contractor will consolidate trips into the fewest possible, use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices (e.g., diesel particulate filters), but in no case less clean than the average fleet mix as set forth in the ARB's latest EMFAC emission database. The contractor will document efforts it undertook to locate newer equipment, alternative fueled equipment (electric, compressed natural gas, or gasoline), and addition of after-market control devices.

Location: The mitigation will apply to all construction areas.

Effectiveness Criteria: Effectiveness will be based on the emissions calculated based on actual equipment used and operating hours with a minimum performance criteria equal to the average fleet mix as set forth in the ARB's latest EMFAC emission database. This will be detailed in the Air Impact Assessment and Monitoring and Reporting Schedule submitted to the SJVAPCD in conjunction with ISR Rule 9510.

Responsible Agency: Reclamation

Monitoring/Reporting Action: Adequacy of the proposed practices will be confirmed with Reclamation construction managers and CSLC monitors as detailed in the Monitoring and Reporting Schedule submitted to the SJVAPCD. The SJVAPCD would prepare a Monitoring and Reporting Schedule Compliance letter upon completion.

Timing: Mitigation will be ongoing over the construction timeframe.

Mitigation Measure AQ-1C (Alternative A): ***Offset Project Construction Emissions through a SJVAPCD Voluntary Emission Reduction Agreement***. This mitigation measure will require Reclamation to enter into a contractual agreement to mitigate by purchasing offsets to net zero the Project's actual emissions from exhaust equipment for ROG and NOx for any year that the emissions are projected to exceed the significance threshold based on the estimated construction emissions for any funded construction phase. This is required under the General Conformity Rule for projects that are above the *de minimis* threshold for ROG or NOx. The agreement will provide funds to the SJVAPCD's Emission Reduction Incentive Program to fund grants for projects that achieve emission reductions, thus offsetting Project-related impacts on air quality. At a

minimum, mitigation/offsets will occur in the year of impact, or as otherwise permitted by 40 CFR Part 93 Section 93.163.

Implementation Action: Reclamation will enter into a contractual agreement to mitigate by purchasing offsets to net zero the Project's actual emissions from exhaust equipment for ROG and NOx for any year that the emissions are projected to exceed the significance threshold based on the estimated construction emissions for any funded construction phase. The mitigation will offset construction emissions by providing funds to the SJVAPCD's Emission Reduction Incentive Program to fund grants for projects that achieve emission reductions.

Location: The mitigation will apply to all construction areas.

Effectiveness Criteria: Effectiveness will be based on actual equipment used and operating hours for any emissions that are not reduced by on-site mitigation. This will be detailed in the Air Impact Assessment and Monitoring and Reporting Schedule submitted to the SJVAPCD in conjunction with ISR Rule 9510.

Responsible Agency: Reclamation

Monitoring/Reporting Action: Adequacy of the proposed practices will be confirmed with the SJVAPCD as detailed in the Monitoring and Reporting Schedule submitted to the SJVAPCD. The SJVAPCD would prepare a Monitoring and Reporting Schedule Compliance letter upon completion.

Timing: Mitigation will be ongoing over the construction timeframe.

Given the current construction phase schedule, the implementation of Mitigation Measures AQ-1A, AQ-1B, and AQ-1C would decrease the ROG and NOx emissions with the remainder of emissions off-set using the Voluntary Emission Reduction Agreement outlined in mitigation measure AQ-1C. In accordance with the SJVAPCD draft GAMAQI, impacts after mitigation would be **less than significant** for Alternative A.

Impact AQ-2 (Alternative A): ***Conflict with Applicable Plans or Policies Related to Air Quality***. Compared to No-Action, Alternative A would implement the Project in Reach 2B and there would be short-term construction activities in the Project area. In addition, there would be a change in the operation related emissions of sources in the Project area. This includes emissions associated with vehicles traveling to the Project area for operation and maintenance of the existing facilities located in the Project area.

The SJVAPCD has several plans and policies relating to air emissions in the SJVAB. These specifically address ozone, PM_{10} and $PM_{2.5}$ as these are designated as non-attainment under the State and national AAQS. As part of this plan, the SJVAPCD has established significance thresholds of allowable emissions from Projects that would ensure consistency with these plans as they work to meet attainment of the Federal and State standards. The Project's emissions are above the ROG and NOx *de minimis*

emission thresholds established by the General Conformity Rule, which would conflict with plans and policies for obtaining national AAQS.

Compared to existing conditions, Project-related ROGs, NOx, PM_{10}, and $PM_{2.5}$ emissions are above the SJVAPCD's annual significance threshold during Project construction under Alternative A. Dispersion modeling of PM_{10} and $PM_{2.5}$ showed that the incremental increase in concentration of PM_{10} and $PM_{2.5}$ would not exceed the significant impact levels and would not be considered to substantially contribute to further exceedances of the ambient air quality standards. However, since ROG and NOx emissions may exceed the SJVAPCD's annual significance threshold, the Project may impede successful implementation of the State air quality attainment plans. Alternative A would result in a **significant** impact.

Mitigation Measure AQ-2 (Alternative A): ***Reduce or Offset Project Emissions.*** Refer to Mitigation Measures AQ-1A, AQ-1B, and AQ-1C (Alternative A). The same measures would be used here. Since Project-related emissions would be above the General Conformity Rule *de minimis* threshold shown in Table 4-6, the Project must satisfy the General Conformity Rule by either reducing emissions below the threshold, enacting a SIP amendment that includes the Project's ROG and NOx emissions, or purchasing offsets for all ROG and NOx emissions for any year in which the emissions exceed 10 tons per year. Compliance with any of these requirements would ensure that the Project does not conflict with applicable portions of the SIP. The mitigation measures AQ-1A, AQ-1B, and AQ-1C would reduce and/or offset construction emissions. Purchasing offsets will contribute to the SJVAPCD emissions reduction incentive program which is part of the strategies outlined in their plans to reach attainment for both ozone and particulate matter. This fund was highlighted as needing additional funds to reach the anticipated project needs for this program. Therefore, by contributing to this fund to offset the Project emissions, Alternative A impacts would be **less than significant**.

Implementation Action: Reduce or offset project emissions by implementing Mitigation Measures AQ-1A, AQ-1B, and AQ-1C.

Location: The mitigation will apply to all construction areas.

Effectiveness Criteria: Effectiveness will be based on actual equipment used and operating hours for any emissions that are not reduced by on-site mitigation. This will be detailed in the Air Impact Assessment and Monitoring and Reporting Schedule submitted to the SJVAPCD in conjunction with ISR Rule 9510.

Responsible Agency: Reclamation

Monitoring/Reporting Action: Adequacy of the proposed practices will be confirmed with the SJVAPCD or Reclamation construction managers and CSLC monitors, as detailed in the Monitoring and Reporting Schedule submitted to the SJVAPCD. The SJVAPCD would prepare a Monitoring and Reporting Schedule Compliance letter upon completion.

Timing: Mitigation will be ongoing over the construction timeframe.

Impact AQ-3 (Alternative A): ***Expose Sensitive Receptors to Substantial Air Pollutants Associated with Construction***. Compared to the No-Action Alternative, Alternative A would implement the Project and there would be short-term construction activities in the Project area. Construction emissions were estimated for the off-road construction equipment and material hauling vehicles which are diesel fueled. These diesel fueled equipment emit the toxic air contaminant diesel particulate matter. The emissions were estimated and along with air dispersion modeling the concentration in the air was estimated. An exposure assessment and health risk assessment was conducted for sensitive receptors in the Project area. The anticipated health impact for excess cancer risk and chronic hazard index are shown in Table 4-9. The threshold of significance is an increase in excess cancer risk greater than 10 in a million or a chronic hazard index greater than 1.

Table 4-9.
Health Impacts at Maximally Exposed Sensitive Receptor

Receptor Type	Alternative	Latitude (UTM)	Longitude (UTM)	Maximum Carcinogen Risk at Receptor in a million	Chronic Hazard Index
Resident Child	A	739738	4072804	77.36	0.04
	B			78.40	0.03
	C			61.60	0.03
	D			70.80	0.03
School Child	A	733752	4071015	60.30	0.03
	B			54.99	0.02
	C			37.03	0.02
	D			38.43	0.02

Notes:
1. The risk is based on a cancer potency factor for diesel particulate matter of 1.1. Individual years' concentration and age specific factors were used to arrive at the total risk.
2. The chronic hazard index is based on a Reference Exposure Level for diesel particulate matter of 5. The year with the highest concentration was used to calculate the chronic hazard index.

Key:
UTM = Universal Transverse Mercator coordinate system northing (latitude) and easting (longitude) in meters.

Sensitive receptors are projected to have an increase in the excess cancer risk for both resident child and school child exposure scenarios. The resident child would potentially be located along San Mateo Avenue which sees a significant amount of material hauling emissions as well as being located near construction work areas. The school child would be at Washington Elementary and would be exposed to material hauling emissions and construction work areas. There is not anticipated to be any non-cancer health effects since the chronic hazard index is less than 1. However, the health risk assessment indicates an increase in cancer risk above the threshold of 10 in a million for sensitive receptors.

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-

Action Alternative). Given the results of the health risk assessment, which indicate that sensitive receptors would have an increase in excess cancer risk above the threshold of 10 in a million, the impact would be **significant**.

Mitigation Measure AQ-3A (Alternative A): ***Reduce Diesel Particulate Matter Emissions from Construction Equipment.*** This mitigation measure will apply to heavy-duty construction equipment used during the construction phase of the Project. All off-road construction diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices (e.g., diesel particulate filters), but in no case less clean than 85 percent reduction in particulate matter compared to a Tier 2 engine. The mitigation would reduce criteria exhaust emissions from construction equipment.

> **Implementation Action:** For off-road construction diesel equipment, the contractor will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices (e.g., diesel particulate filters), but in no case less clean than 85 percent reduction in particulate matter compared to a Tier 2 engine.
>
> **Location:** The mitigation will apply to all construction areas.
>
> **Effectiveness Criteria:** Effectiveness will be based on use of ARB certified after-market control devices or EPA certified engines.
>
> **Responsible Agency:** Reclamation
>
> **Monitoring/Reporting Action:** Adequacy of the proposed practices will be confirmed with Reclamation construction managers and CSLC monitors.
>
> **Timing:** Mitigation will be ongoing over the construction timeframe.

Mitigation Measure AQ-3B (Alternative A): ***Reduce Diesel Particulate Matter Emissions from Material Hauling Vehicles.*** This mitigation measure will apply to material hauling vehicles used during the construction phase of the Project. Material hauling trips will be consolidated into the fewest trips possible. All material-hauling diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices (e.g., diesel particulate filters), but in no case less clean than the average fleet mix as set forth in the ARB's latest EMFAC emission database to any vehicle used that the contractor has control over (ARB 2007b). The contractor will document efforts it undertook to locate newer equipment, alternative fueled equipment (electric, compressed natural gas, or gasoline), and addition of after-market control devices. The mitigation would reduce criteria exhaust emissions from material hauling vehicles.

> **Implementation Action:** For material hauling vehicles, the contractor will consolidate trips into the fewest possible, use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices (e.g., diesel particulate filters), but in no case less clean than the

average fleet mix as set forth in the ARB's latest EMFAC emission database. The contractor will document efforts it undertook to locate newer equipment, alternative fueled equipment (electric, compressed natural gas, or gasoline), and addition of after-market control devices.

Location: The mitigation will apply to all construction areas.

Effectiveness Criteria: Effectiveness will be based on the emissions calculated based on actual equipment used and operating hours with a minimum performance criteria equal to the average fleet mix as set forth in the ARB's latest EMFAC emission database. This will be detailed in the Air Impact Assessment and Monitoring and Reporting Schedule submitted to the SJVAPCD in conjunction with ISR Rule 9510.

Responsible Agency: Reclamation

Monitoring/Reporting Action: Adequacy of the proposed practices will be confirmed with Reclamation construction managers and CSLC monitors as detailed in the Monitoring and Reporting Schedule submitted to the SJVAPCD. The SJVAPCD would prepare a Monitoring and Reporting Schedule Compliance letter upon completion.

Timing: Mitigation will be ongoing over the construction timeframe.

If it is assumed that mitigation measures AQ-3A and AQ-3B could mitigate emissions by 85 percent for Alternative A, which is the maximum estimated if diesel particulate filters can be used by all equipment and trucks, this risk would be reduced to 18.3 in a million for the resident child. The excess cancer risk would still be above 10 in a million. This is due to the size of the construction Project and the receptors' close proximity to the roadway. Alternative A after mitigation would still have a substantial effect on exposure of sensitive receptors to health impacts. After mitigation, Alternative A impacts would remain **significant and unavoidable** in exposing sensitive receptors to substantial air pollutants.

Impact AQ-4 (Alternative A): ***Create Excess Amounts of Operational Related Criteria Air Pollutants that Exceed SJVAPCD Thresholds of Significance or Cause or Contribute to Exceedances of the AAQS***. Compared to the No-Action Alternative, Alternative A would implement the Project and there would be some operational activities in the Project area. Operation emissions are estimated to be from workers driving to the Project area to perform routine maintenance and operation activities associated with the water control structures. These emissions were quantified based on the anticipated number of worker trips. The operational emissions are shown in Table 4-10. These operational emissions were compared to the SJVAPCD's significance thresholds and the General Conformity Rule *de minimis* thresholds. The operational emissions do not exceed these thresholds.

Alternative A would also convert active agricultural areas to natural areas and open space reducing agricultural emissions in the Project area. Agricultural field operations, such as

tilling, planting, weeding, fertilizing, harvesting, and spreading of manure or compost can produce air pollution emissions from the mechanical movement of soil or from engine operation and fuel combustion. For example, wind erosion can transport dust after tillage (increasing PM_{10}) and fertilizer used for crops release ammonia to the atmosphere which mixes with other emissions to form microscopic airborne particles (increasing $PM_{2.5}$).

When comparing Alternative A to existing conditions, impacts would be similar to those described in in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). Therefore, the operational related criteria air pollutants would result in a **less than significant** impact**.**

Table 4-10.
Total Operational Emissions

Alt	CO	NOx	ROG	SOx	PM_{10} Exhaust	PM_{10} Fugitive	PM_{10} Total	$PM_{2.5}$ Exhaust	$PM_{2.5}$ Fugitive	$PM_{2.5}$ Total
	tons									
A	0.032	0.004	0.002	0.0001	0.0005	0.024	0.0243	0.0003	0.006	0.0062
B	0.032	0.004	0.002	0.0001	0.0005	0.025	0.0256	0.0003	0.006	0.0066
C	0.032	0.004	0.002	0.0001	0.0005	0.025	0.0257	0.0003	0.006	0.0066
D	0.031	0.004	0.002	0.0001	0.0005	0.026	0.0262	0.0003	0.006	0.0067
SJVAPCD CEQA Threshold	100	10	10	27	NA	NA	15	NA	NA	15
General Conformity *de minimis* Threshold	NA	10	10	NA	NA	NA	100	NA	NA	100

Notes:

1. Emission factors are based on EMFAC for 2014 to be conservative as the starting year of operation varies (ARB 2007b).
2. Fugitive dust emissions are from travel on paved roads based on AP-42 Chapter 13.1.

Key:

CEQA = California Environmental Quality Act
CO = carbon monoxide
NA = not applicable
NO_X = nitrogen oxides
PM_{10} = particulate matter smaller than or equal to 10 microns in diameter
$PM_{2.5}$ = particulate matter smaller than or equal to 2.5 microns in diameter
ROG = reactive organic gas
SJVAPCD = San Joaquin Valley Air Pollution Control District
SO_X = sulfur oxides

Impact AQ-5 (Alternative A): ***Expose Sensitive Receptors to Substantial Air Pollutants Associated with Operation***. Compared to the No-Action Alternative, Alternative A would implement the Project and there would be operational activities in the Project area. Operational activities would be associated with workers driving to the site to perform routine maintenance and operation activities associated with the water control structures. Most of these vehicles would be gasoline fueled and the gasoline exhaust has significantly less toxicity compared to diesel exhaust. The number of additional trips added to the area near sensitive receptors is minimal. Therefore, there would not be a substantial source of operational related toxic air contaminants.

When comparing Alternative A to existing conditions, impacts would be similar to those described in in the preceding paragraph (i.e., the comparison of Alternative A to the No-Action Alternative). As a result, there would be a **less than significant** impact on sensitive receptors due to toxic air contaminants from Project operation.

Impact AQ-6 (Alternative A): *Create Objectionable Odors from Construction.* Compared to the No-Action Alternative, Alternative A would implement the Project and there would be construction activities in the Project area. Construction equipment and material hauling vehicles using diesel fuel may emit objectionable odors associated with combustion of the diesel fuel. However, these emissions would be transitory.

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative A to the No-Action Alternative). Therefore, odor impacts associated with diesel combustion during construction activities would be a **less than significant** impact from odors.

Impact AQ-7 (Alternative A): *Create Objectionable Odors from Operation*. Compared to the No-Action Alternative, Alternative A would implement the Project and there would be operational activities in the Project area. The operational activities are associated with workers commuting to the Project area to perform routine operation and maintenance. The worker vehicles are not expected to noticeably increase the amount of odors associated with traffic along roads in the Project area.

When comparing Alternative A to existing conditions, impacts would be similar to those described in in the preceding paragraph (i.e., the comparison of Alternative A to the No-Action Alternative). Therefore, odor impacts associated with operational activities would result in a **less than significant** impact.

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Alternative B would include construction of Project features including a Compact Bypass channel, a new levee system with a wide, consensus-based floodplain encompassing the river channel, and the Compact Bypass Bifurcation Structure with fish passage facility. Other key features include construction of a fish passage facility at the San Joaquin River control structure of the Chowchilla Bifurcation Structure, the re-route of Drive 10 ½ (across the Compact Bypass Control Structure), and removal of the San Mateo Avenue crossing. Construction activity is expected to occur intermittently over an approximate 157-month timeframe.

Impact AQ-1 (Alternative B*): Create Excess Amounts of Construction Related Criteria Air Pollutants that Exceed SJVAPCD Thresholds of Significance or Cause or Contribute to Exceedances of the AAQS*. Compared to No-Action, Alternative B would implement the Project and there would be short-term construction activities in the Project area. Construction emissions were estimated for the off-road construction equipment, material hauling vehicles, worker commute vehicles, and fugitive dust emissions from construction and travel on roads. The construction emissions shown in Table 4-6 were compared to the General Conformity Rule *de minimis* threshold for NEPA. The General

Conformity Rule *de minimis* threshold would be exceeded for NOx and ROG and therefore construction emissions would be substantial.

Total construction emissions were compared to the SJVAPCD's significance thresholds for CEQA. CO, NOx, ROG, PM_{10}, and $PM_{2.5}$ criteria pollutants are above the annual emissions thresholds which indicate that the Project could cause a significant impact compared to existing conditions. The CO, $PM_{10,}$ and $PM_{2.5}$ emissions were modeled using air dispersion modeling to determine if the concentration, including background, was below the AAQS or below a significant impact level in the local area. NOx and ROG emissions were not modeled as these are ozone precursors and contribute to the regional ozone problem.

The modeled CO maximum concentration from Project sources is shown in Table 4-7. This was combined with the background concentration based on the average 1 hour for 2010 to 2013. This indicates that at the point of maximum impact, the CO concentration is less than the AAQS. Therefore the Project, after modeling, indicates that there is less than significant impact for CO.

The modeled PM_{10} and $PM_{2.5}$ maximum concentrations from Project sources are shown in Table 4-8. Since the SJVAB is already in non-attainment for both PM_{10} and $PM_{2.5}$, a concentration above the significant impact level would contribute to the existing exceedances of the AAQS. The significant impact levels are based on the Prevention of Significant Deterioration thresholds set by the SJVAPCD. The Fugitive PM_{10} annual significant impact level is 2.08 $\mu g/m^3$. The EPA vacated the $PM_{2.5}$ and Fugitive $PM_{2.5}$ annual significant impact level in 2013. As there is no adopted $PM_{2.5}$ significant impact level, the SJVAPCD recommends using the corresponding PM_{10} significant impact level for both PM_{10} and $PM_{2.5}$ analyses (Villalvazo, pers. comm., 2014). Therefore, 2.08 $\mu g/m^3$ is used as the Fugitive $PM_{2.5}$ annual significant impact level. As shown in Table 4-8 the PM_{10} and $PM_{2.5}$ Project concentrations are below this significance level. Therefore, the construction emissions of PM_{10} and $PM_{2.5}$ are less than significant impacts. The calculated fugitive dust emissions would be further reduced if control measures from compliance with SJVAPCD Regulation VIII were quantified; as such, the fugitive dust emissions stated here are conservative because these control measures would be required through mandatory compliance with SJVAPCD Regulation VIII. Compliance with SJVAPCD Regulation VIII would reduce PM_{10} emissions (predominantly dust/dirt) generated by human activity, including construction and demolition activities, road construction, bulk materials storage, paved and unpaved roads, carryout and track out, and landfill operations.

As discussed above, NOx, ROG are above the SJVAPCD annual emissions thresholds for regional air quality. Therefore, Alternative B would cause a **significant** impact for construction-related criteria air pollutants for NOx and ROG.

Mitigation Measure AQ-1A (Alternative B): ***Reduce Criteria Exhaust Emissions from Construction Equipment.*** Refer to Mitigation Measure AQ-1A (Alternative A). The same measure would be used here. All off-road construction diesel equipment will use

the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices.

Mitigation Measure AQ-1B (Alternative B): ***Reduce Criteria Exhaust Emissions from Material Hauling Vehicles.*** Refer to Mitigation Measure AQ-1B (Alternative A). The same measure would be used here. Material hauling trips will be consolidated into the fewest trips possible. All material hauling diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices.

Mitigation Measure AQ-1C (Alternative B): ***Offset Project Construction Emissions through a SJVAPCD Voluntary Emission Reduction Agreement***. Refer to Mitigation Measure AQ-1C (Alternative A). The same measure would be used here. This mitigation measure will require Reclamation to enter into a contractual agreement to mitigate by purchasing offset to net zero the Project's actual emissions from exhaust equipment for ROG and NOx.

Implementation of these mitigation measures would decrease the ROG and NOx emissions with the remainder of emissions off-set using the Voluntary Emission Reduction Agreement outlined in mitigation measure AQ-1C. According to the SJVAPCD draft GAMAQI, impacts after mitigation would be **less than significant**.

Impact AQ-2 (Alternative B): ***Conflict with Applicable Plans or Policies Related to Air Quality***. Compared to No-Action, Alternative B would implement the Project and there would be short-term construction activities in the Project area. In addition, there would be a change in the operations related emissions from sources in the Project area. This includes emissions associated with vehicles traveling to the Project area for operation and maintenance of the existing facilities located in the Project area. The SJVAPCD has several plans and policies relating to air emissions in the SJVAB. These specifically address ozone, PM_{10} and $PM_{2.5}$ as these are designated as non-attainment under the State and national AAQS. As part of this plan the SJVAPCD has established significance thresholds of allowable emissions from Projects that would ensure consistency with these plans as they work to meet attainment of the Federal and State standards. These thresholds of significance are also consistent with the General Conformity Rule *de minimis* thresholds. The Project's emissions are above the ROG and NOx emission thresholds established by the General Conformity Rule. This would conflict with plans and policies for obtaining national AAQS.

Compared to existing conditions, Project emissions of ROG, NOx, PM_{10}, and $PM_{2.5}$ are above the SJVAPCD's annual significance threshold during Project construction under Alternative B. Dispersion modeling of PM_{10} and $PM_{2.5}$ showed that the incremental increase in concentration of PM_{10} and $PM_{2.5}$ would not exceed the significant impact levels and would not be considered to substantially contribute to further exceedances of the ambient air quality standards. However, since ROG and NOx emissions may exceed the SJVAPCD's annual significance threshold, the Project may impede the implementation of the State air quality attainment plans. Alternative B would result in a **significant** impact.

Mitigation Measure AQ-2 (Alternative B): ***Reduce or Offset Project Emissions.*** Refer to Mitigation Measure AQ-2 (Alternative A). The same measure would be used here. This mitigation measure would reduce criteria exhaust emissions from construction equipment and material hauling vehicles and would offset project construction emissions through a SJVAPCD Voluntary Emission Reduction Agreement. Impacts after mitigation would be **less than significant**.

Impact AQ-3 (Alternative B): ***Expose Sensitive Receptors to Substantial Air Pollutants Associated with Construction***. Compared to the No-Action Alternative, Alternative B would implement the Project and there would be short-term construction activities in the Project area. Construction emissions were estimated for the off-road construction equipment and material hauling vehicles which are diesel fueled. These diesel fueled equipment emit the toxic air contaminant diesel particulate matter. The emissions were estimated and along with air dispersion modeling the concentration in the air was estimated. An exposure assessment and health risk assessment was conducted for sensitive receptors in the Project area. The anticipated health impact for excess cancer risk and chronic hazard index are shown in Table 4-9. The threshold of significance is an increase in excess cancer risk greater than 10 in a million or a chronic hazard index greater than 1.

Sensitive receptors are projected to have an increase in the excess cancer risk for both a resident child and school child exposure scenario. The resident child is located along San Mateo Avenue which sees a significant amount of material hauling emissions as well as being located near construction work areas. The school child is at Washington Elementary and is exposed to material hauling emissions and construction work areas. There is not anticipated to be any non-cancer health effects since the chronic hazard index is less than 1. However, the health risk assessment indicates an increase in cancer risk above the threshold of 10 in a million for sensitive receptors.

When comparing Alternative B to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative B to the No-Action Alternative). Given the results of the health risk assessment which indicate that sensitive receptors would have an increase in excess cancer risk above the threshold of 10 in a million, the impact would be **significant**.

Mitigation Measure AQ-3A (Alternative B): ***Reduce Diesel Particulate Matter Emissions from Construction Equipment.*** Refer to Mitigation Measure AQ-3A (Alternative A). The same measure would be used here. All off-road construction diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices.

Mitigation Measure AQ-3B (Alternative B): ***Reduce Diesel Particulate Matter Emissions from Material Hauling Vehicles.*** Refer to Mitigation Measure AQ-3B (Alternative A). The same measure would be used here. Material hauling trips will be consolidated into the fewest trips possible. All material hauling diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices.

If it is assumed that mitigation measures AQ-3A and AQ-3B could mitigate emissions by 85 percent which is the maximum estimated if diesel particulate filters can be used by all equipment and trucks, the risk associated with Alternative B would be reduced to 17.85 in a million for the resident child. The excess cancer risk would still be above 10 in a million. This is due to the size of the construction project and the receptors' close proximity to the roadway. Alternative B after mitigation would still have a substantial effect on exposure of sensitive receptors to health impacts. After mitigation, Alternative B impacts would remain **significant and unavoidable** in exposing sensitive receptors to substantial air pollutants.

Impact AQ-4 (Alternative B): ***Create Excess Amounts of Operational Related Criteria Air Pollutants that Exceed SJVAPCD Thresholds of Significance or Cause or Contribute to Exceedances of the AAQS***. Compared to the No-Action Alternative, Alternative B would implement the Project and there would be some operational activities in the Project area. Operation emissions are estimated to be from workers driving to the Project area to do routine maintenance and operation activities associated with the water control structures. There are no other sources of emissions anticipated with operation of the Project. These emissions were quantified based on the anticipated number of worker trips. The operational emissions are shown in Table 4-10. These operational emissions were compared to the SJVAPCD's significance thresholds and the General Conformity Rule *de minimis* thresholds. The operational emissions do not exceed these thresholds.

Alternative B would also convert active agricultural areas to natural areas and open space reducing agricultural emissions in the Project area. Agricultural field operations, such as tilling, planting, weeding, fertilizing, harvesting, and spreading of manure or compost can produce air pollution emissions from the mechanical movement of soil or from engine operation and fuel combustion.

When comparing Alternative B to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative B to the No-Action Alternative). Therefore, the operational related criteria air pollutants would result in a **less than significant** impact.

Impact AQ-5 (Alternative B): ***Expose Sensitive Receptors to Substantial Air Pollutants Associated with Operation***. Compared to the No-Action Alternative, Alternative B would implement the Project and there would be operational activities in the Project area. Operational activities would be associated with workers driving to the site to perform routine maintenance and operation activities associated with the water control structures. Most of these vehicles would be gasoline fueled and the gasoline exhaust has significantly less toxicity compared to diesel exhaust. The number of additional trips added to the area near sensitive receptors is minimal. Therefore, there would not be a substantial source of operational related toxic air contaminants.

When comparing Alternative B to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative B to the No-

Action Alternative). As a result, there would be a **less than significant** impact on sensitive receptors due to toxic air contaminants from operation of Alternative B.

Impact AQ-6 (Alternative B): *Create Objectionable Odors from Construction.* Compared to the No-Action Alternative, Alternative B would implement the Project and there would be construction activities in the Project area. Construction equipment and material hauling vehicles using diesel fuel may emit objectionable odors associated with combustion of the diesel fuel. However, these emissions would be transitory.

When comparing Alternative B to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative B to the No-Action Alternative). Therefore, odor impacts of Alternative B associated with diesel combustion during construction activities would be a **less than significant** impact from odors.

Impact AQ-7 (Alternative B): *Create Objectionable Odors from Operation*. Compared to the No-Action Alternative, Alternative B would implement the Project and there would be operational activities in the Project area. The operational activities are associated with workers commuting to the Project area to perform routine operation and maintenance. The worker vehicles are not expected to noticeably increase the amount of odors associated with traffic along roads in the Project area.

When comparing Alternative B to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative B to the No-Action Alternative). Therefore, odor impacts of Alternative B associated with operational activities would result in a **less than significant** impact.

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Alternative C would include construction of Project features including Fresno Slough Dam, a new levee system with a narrow floodplain encompassing the river channel, and the Short Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the Short Canal control structure and fish screen, construction of a fish passage facility at the San Joaquin River control structure of the Chowchilla Bifurcation Structure, modification of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 133-month timeframe.

Impact AQ-1 (Alternative C*): Create Excess Amounts of Construction Related Criteria Air Pollutants that Exceed SJVAPCD Thresholds of Significance or Cause or Contribute to Exceedances of the AAQS*. Compared to No-Action, Alternative C would implement the Project and there would be short-term construction activities in the Project area. Construction emissions were estimated for the off-road construction equipment, material hauling vehicles, worker commute vehicles, and fugitive dust emissions from construction and travel on roads. These construction emissions shown in Table 4-6 were compared to the General Conformity Rule *de minimis* thresholds for NEPA. The General Conformity Rule *de minimis* threshold would be exceeded for NOx and ROG and therefore construction emissions would be substantial.

Total construction emissions were compared to the SJVAPCD's significance thresholds for CEQA. CO, NOx, ROG, PM_{10}, and $PM_{2.5}$ criteria pollutants are above the annual emissions thresholds which indicate that the Project could cause a significant impact compared to existing conditions. The CO, $PM_{10,}$ and $PM_{2.5}$ emissions were modeled using air dispersion modeling to determine if the concentration including background was below the AAQS or below a significant impact level in the local area. NOx and ROG emissions were not modeled as these are ozone precursors and contribute to the regional ozone problem.

The modeled CO maximum concentration from project sources is shown in Table 4-7. This was combined with the background concentration based on the average 1 hour for 2010 to 2013. This indicates that at the point of maximum impact, the CO concentration is less than the AAQS. Therefore the Project, after modeling, indicates that it is less than significant impact for CO.

The modeled PM_{10} and $PM_{2.5}$ maximum concentrations from Project sources are shown in Table 4-8. Since the SJVAB is already significant for both PM_{10} and $PM_{2.5}$, a significant impact would significantly contribute to the existing exceedances of the AAQS. These significant impact levels are based on the Prevention of Significant Deterioration thresholds set by the SJVAPCD. The Fugitive PM_{10} annual significant impact level is 2.08 $\mu g/m^3$. The EPA vacated the $PM_{2.5}$ and Fugitive $PM_{2.5}$ annual significant impact level in 2013. As there is no adopted $PM_{2.5}$ significant impact level, the SJVAPCD recommends using the corresponding PM_{10} significant impact level for both PM_{10} and $PM_{2.5}$ analyses (Villalvazo, pers. comm., 2014). Therefore, 2.08 $\mu g/m^3$ is used as the Fugitive $PM_{2.5}$ annual significant impact level. As shown in Table 4-8 the PM_{10} and $PM_{2.5}$ Project concentrations are below this significance level. Therefore, after modeling, the construction emissions of PM_{10} and $PM_{2.5}$ are less than significant impacts. The calculated fugitive dust emissions would be further reduced if control measures from compliance with SJVAPCD Regulation VIII were quantified; as such, the fugitive dust emissions stated here are conservative because these control measures would be required through mandatory compliance with SJVAPCD Regulation VIII. Compliance with SJVAPCD Regulation VIII would reduce PM_{10} emissions (predominantly dust/dirt) generated by human activity, including construction and demolition activities, road construction, bulk materials storage, paved and unpaved roads, carryout and track out, and landfill operations.

As discussed above, NOx, ROG are above the SJVAPCD annual emissions thresholds for regional air quality. Therefore, Alterative C would cause a **significant** impact for construction-related criteria air pollutants for NOx and ROG.

Mitigation Measure AQ-1A (Alternative C): ***Reduce Criteria Exhaust Emissions from Construction Equipment.*** Refer to Mitigation Measure AQ-1A (Alternative A). The same measure would be used here. All off-road construction diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices.

Mitigation Measure AQ-1B (Alternative C): ***Reduce Criteria Exhaust Emissions from Material Hauling Vehicles.*** Refer to Mitigation Measure AQ-1B (Alternative A). The same measure would be used here. Material hauling trips will be consolidated into the fewest trips possible. All material hauling diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices.

Mitigation Measure AQ-1C (Alternative C): ***Offset Project Construction Emissions through a SJVAPCD Voluntary Emission Reduction Agreement***. Refer to Mitigation Measure AQ-1C (Alternative A). The same measure would be used here. This mitigation measure will require Reclamation to enter into a contractual agreement to mitigate by purchasing offset to net zero the project's actual emissions from equipment exhaust for ROG and NOx.

Implementation of these mitigation measures would decrease the ROG and NOx emissions with the remainder of emissions off-set using the Voluntary Emission Reduction Agreement outlined in mitigation measure AQ-1C. According to the SJVAPCD draft GAMAQI, impacts after mitigation would be **less than significant**.

Impact AQ-2 (Alternative C): ***Conflict with Applicable Plans or Policies Related to Air Quality***. Compared to No-Action, Alternative C would implement the Project and there would be short-term construction activities in the Project area. In addition, there would be a change in the operations related emissions from sources in the Project area. This includes emissions associated with vehicles traveling to the Project area for operation and maintenance of the existing facilities located in the Project area. The SJVAPCD has several plans and policies relating to air emissions in the SJVAB. These specifically address ozone, PM_{10} and $PM_{2.5}$ as these are designated as non-attainment under the State and national AAQS. As part of this plan the SJVAPCD has established significance thresholds of allowable emissions from Projects that would ensure consistency with these plans as they work to meet attainment of the Federal and State standards. These thresholds of significance are also consistent with the General Conformity Rule *de minimis* thresholds. The Project's emissions are above the ROG and NOx emission thresholds established by the General Conformity Rule. This would conflict with plans and policies for obtaining national AAQS.

Compared to existing conditions, Project emissions of ROG, NOx, PM_{10}, and $PM_{2.5}$ are above the SJVAPCD's annual significance threshold during Project construction under Alternative C. Dispersion modeling of PM_{10} and $PM_{2.5}$ showed that the incremental increase in concentration of PM_{10} and $PM_{2.5}$ would not exceed the significant impact levels and would not be considered to substantially contribute to further exceedances of the ambient air quality standards. However, since ROG and NOx emissions may exceed the SJVAPCD's annual significance threshold, the Project may impede the implementation of the State air quality attainment plans. Alternative C would result in a **significant** impact.

Mitigation Measure AQ-2 (Alternative C): ***Reduce or Offset Project Emissions.*** Refer to Mitigation Measure AQ-2 (Alternative A). The same measure would be used here.

This mitigation measure would reduce criteria exhaust emissions from construction equipment and material hauling vehicles and would offset project construction emissions through a SJVAPCD Voluntary Emission Reduction Agreement. Impacts after mitigation would be **less than significant**.

Impact AQ-3 (Alternative C): ***Expose Sensitive Receptors to Substantial Air Pollutants Associated with Construction***. Compared to the No-Action Alternative, Alternative C would implement the Project and there would be short-term construction activities in the Project area. Construction emissions were estimated for the off-road construction equipment and material hauling vehicles which are diesel fueled. These diesel fueled equipment emit the toxic air contaminant diesel particulate matter. The emissions were estimated and along with air dispersion modeling the concentration in the air was estimated. An exposure assessment and health risk assessment was conducted for sensitive receptors in the Project area. The anticipated health impact for excess cancer risk and chronic hazard index are shown in Table 4.9. The threshold of significance is an increase in excess cancer risk greater than 10 in a million or a chronic hazard index greater than 1.

Sensitive receptors are projected to have an increase in the excess cancer risk for both a resident child and school child exposure scenario. The resident child is located along San Mateo Avenue which sees a significant amount of material hauling emissions as well as being located near construction work areas. The school child is at Washington Elementary and is exposed to material hauling emissions and construction work areas. There is not anticipated to be any non-cancer health effects since the chronic hazard index is less than 1. However, the health risk assessment indicates an increase in cancer risk above the threshold of 10 in a million for sensitive receptors.

When comparing Alternative C to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative C to the No-Action Alternative). Given the results of the health risk assessment which indicate that sensitive receptors would have an increase in excess cancer risk above the threshold of 10 in a million, the impact would be **significant**.

Mitigation Measure AQ-3A (Alternative C): ***Reduce Diesel Particulate Matter Emissions from Construction Equipment.*** Refer to Mitigation Measure AQ-3A (Alternative A). The same measure would be used here. All off-road construction diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices.

Mitigation Measure AQ-3B (Alternative C): ***Reduce Diesel Particulate Matter Emissions from Material Hauling Vehicles.*** Refer to Mitigation Measure AQ-3B (Alternative A). The same measure would be used here. Material hauling trips will be consolidated into the fewest trips possible. All material hauling diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices.

If it is assumed that mitigation measures AQ-3A and AQ-3B could mitigate emissions by 85 percent which is the maximum estimated if diesel particulate filters can be used by all equipment and trucks, the risk associated with Alternative C would be reduced to 13.95 in a million for the resident child. The excess cancer risk would still be above 10 in a million. This is due to the size of the construction project and the receptors' close proximity to the roadway. Alternative C after mitigation would still have a substantial effect on exposure of sensitive receptors to health impacts. After mitigation, Alternative C impacts would remain **significant and unavoidable** in exposing sensitive receptors to substantial air pollutants.

Impact AQ-4 (Alternative C): ***Create Excess Amounts of Operational Related Criteria Air Pollutants that Exceed SJVAPCD Thresholds of Significance or Cause or Contribute to Exceedances of the AAQS***. Compared to the No-Action Alternative, Alternative C would implement the Project and there would be some operational activities in the Project area. Operation emissions are estimated to be from workers driving to the Project area to do routine maintenance and operation activities associated with the water control structures. There are no other sources of emissions anticipated with operation of the Project. These emissions were quantified based on the anticipated number of worker trips. The operational emissions are shown in Table 4-10.These operational emissions were compared to the SJVAPCD's significance thresholds and the General Conformity Rule *de minimis* thresholds. The operational emissions do not exceed these thresholds.

Alternative C would also convert active agricultural areas to natural areas and open space reducing agricultural emissions in the Project area. Agricultural field operations, such as tilling, planting, weeding, fertilizing, harvesting, and spreading of manure or compost can produce air pollution emissions from the mechanical movement of soil or from engine operation and fuel combustion.

When comparing Alternative C to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative C to the No-Action Alternative). Therefore, the operational related criteria air pollutants would result in a **less than significant** impact.

Impact AQ-5 (Alternative C): ***Expose Sensitive Receptors to Substantial Air Pollutants Associated with Operation***. Compared to the No-Action Alternative, Alternative C would implement the Project and there would be operational activities in the Project area. Operational activities would be associated with workers driving to the site to perform routine maintenance and operation activities associated with the water control structures. Most of these vehicles would be gasoline fueled and the gasoline exhaust has significantly less toxicity compared to diesel exhaust. The number of additional trips added to the area near sensitive receptors is minimal. Therefore, there would not be a substantial source of operational related toxic air contaminants.

When comparing Alternative C to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative C to the No-

Action Alternative). As a result, there would be a **less than significant** impact on sensitive receptors due to toxic air contaminants from operation of Alternative C.

Impact AQ-6 (Alternative C): *Create Objectionable Odors from Construction.* Compared to the No-Action Alternative, Alternative C would implement the Project and there would be construction activities in the Project area. Construction equipment and material hauling vehicles using diesel fuel may emit objectionable odors associated with combustion of the diesel fuel. However, these emissions would be transitory.

When comparing Alternative C to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative C to the No-Action Alternative). Therefore, odor impacts of Alternative C associated with diesel combustion during construction activities would be a **less than significant** impact from odors.

Impact AQ-7 (Alternative C): *Create Objectionable Odors from Operation*. Compared to the No-Action Alternative, Alternative C would implement the Project and there would be operational activities in the Project area. The operational activities are associated with workers commuting to the Project area to perform routine operation and maintenance. The worker vehicles are not expected to noticeably increase the amount of odors associated with traffic along roads in the Project area.

When comparing Alternative C to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative C to the No-Action Alternative). Therefore, odor impacts of Alternative C associated with operational activities would result in a **less than significant** impact.

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Alternative D would include construction of Project features including Fresno Slough Dam, a new levee system with a wide floodplain encompassing the river channel, and the North Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the North Canal bifurcation structure, and the North Canal fish passage facility, removal of the San Joaquin River control structure of the Chowchilla Bifurcation Structure, removal of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 158-month timeframe.

Impact AQ-1 (Alternative D*): Create Excess Amounts of Construction Related Criteria Air Pollutants that Exceed SJVAPCD Thresholds of Significance or Cause or Contribute to Exceedances of the AAQS*. Compared to No-Action, Alternative D would implement the Project and there would be short-term construction activities in the Project area. Construction emissions were estimated for the off-road construction equipment, material hauling vehicles, worker commute vehicles, and fugitive dust emissions from construction and travel on roads. The construction emissions shown in Table 4-6 were compared to the General Conformity Rule *de minimis* thresholds for NEPA. The General Conformity Rule *de minimis* threshold would be exceeded for NOx and ROG and therefore construction emissions would be substantial.

Total construction emissions were compared to the SJVAPCD's significance thresholds for CEQA. CO, NOx, ROG, PM_{10}, and $PM_{2.5}$ criteria pollutants are above the annual emissions thresholds which indicate that the Project could cause a significant impact compared to existing conditions. The CO, $PM_{10,}$ and $PM_{2.5}$ emissions were modeled using air dispersion modeling to determine if the concentration including background was below the AAQS or below a significant impact level in the local area. NOx and ROG emissions were not modeled as these are ozone precursors and contribute to the regional ozone problem.

The modeled CO maximum concentration from project sources is shown in Table 4-7. This was combined with the background concentration based on the average 1 hour for 2010 to 2013. This indicates that at the point of maximum impact, the CO concentration is less than the AAQS. Therefore the Project, after modeling, indicates that it is less than significant impact for CO.

The modeled PM_{10} and $PM_{2.5}$ maximum concentrations from Project sources are shown in Table 4-8. Since the SJVAB is already significant for both PM_{10} and $PM_{2.5}$, a significant impact would significantly contribute to the existing exceedances of the AAQS. These significant impact levels are based on the Prevention of Significant Deterioration thresholds set by the SJVAPCD. The Fugitive PM_{10} annual significant impact level is 2.08 $\mu g/m^3$. The EPA vacated the $PM_{2.5}$ and Fugitive $PM_{2.5}$ annual significant impact level in 2013. As there is no adopted $PM_{2.5}$ significant impact level, the SJVAPCD recommends using the corresponding PM_{10} significant impact level for both PM_{10} and $PM_{2.5}$ analyses (Villalvazo, pers. comm., 2014). Therefore, 2.08 $\mu g/m^3$ is used as the Fugitive $PM_{2.5}$ annual significant impact level. As shown in Table 4-8 the PM_{10} and $PM_{2.5}$ Project concentrations are below this significance level. Therefore, after modeling, the construction emissions of PM_{10} and $PM_{2.5}$ are less than significant impacts. The calculated fugitive dust emissions would be further reduced if control measures from compliance with SJVAPCD Regulation VIII were quantified; as such, the fugitive dust emissions stated here are conservative because these control measures would be required through mandatory compliance with SJVAPCD Regulation VIII. Compliance with SJVAPCD Regulation VIII would reduce PM_{10} emissions (predominantly dust/dirt) generated by human activity, including construction and demolition activities, road construction, bulk materials storage, paved and unpaved roads, carryout and track out, and landfill operations.

As discussed above, NOx, ROG are above the SJVAPCD annual emissions thresholds for regional air quality. Therefore, Alternative D would cause a **significant** impact for construction-related criteria air pollutants for NOx and ROG.

Mitigation Measure AQ-1A (Alternative D): ***Reduce Criteria Exhaust Emissions from Construction Equipment.*** Refer to Mitigation Measure AQ-1A (Alternative A). The same measure would be used here. All off-road construction diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices.

Mitigation Measure AQ-1B (Alternative D): ***Reduce Criteria Exhaust Emissions from Material Hauling Vehicles.*** Refer to Mitigation Measure AQ-1B (Alternative A). The same measure would be used here. Material hauling trips will be consolidated into the fewest trips possible. All material hauling diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices.

Mitigation Measure AQ-1C (Alternative D): ***Offset Project Construction Emissions through a SJVAPCD Voluntary Emission Reduction Agreement***. Refer to Mitigation Measure AQ-1C (Alternative A). The same measure would be used here. This mitigation measure will require Reclamation to enter into a contractual agreement to mitigate by purchasing offset to net zero the project's actual emissions from equipment exhaust for ROG and NOx.

Implementation of these mitigation measures would decrease the ROG and NOx emissions with the remainder of emissions off-set using the Voluntary Emission Reduction Agreement outlined in mitigation measure AQ-1C. According to the SJVAPCD draft GAMAQI, impacts after mitigations would be **less than significant**.

Impact AQ-2 (Alternative D): ***Conflict with Applicable Plans or Policies Related to Air Quality***. Compared to No-Action, Alternative D would implement the Project and there would be short-term construction activities in the Project area. In addition, there would be a change in the operations related emissions from sources in the Project area. This includes emissions associated with vehicles traveling to the Project area for operation and maintenance of the existing facilities located in the Project area. The SJVAPCD has several plans and policies relating to air emissions in the SJVAB. These specifically address ozone, $PM_{10,}$ and $PM_{2.5,}$ as these are designated as non-attainment under the State and national AAQS. As part of this plan the SJVAPCD has established significance thresholds of allowable emissions from Projects that would ensure consistency with these plans as they work to meet attainment of the Federal and State standards. These thresholds of significance are also consistent with the General Conformity Rule *de minimis* thresholds. The Project's emissions are above the ROG and NOx emission thresholds established by the General Conformity Rule. This would conflict with plans and policies for obtaining national AAQS.

Compared to existing conditions, Project emissions of ROG, NOx, PM_{10}, and $PM_{2.5}$ are above the SJVAPCD's annual significance threshold during Project construction under Alternative D. Dispersion modeling of PM_{10} and $PM_{2.5}$ showed that the incremental increase in concentration of PM_{10} and $PM_{2.5}$ would not exceed the significant impact levels and would not be considered to substantially contribute to further exceedances of the ambient air quality standards. However, since ROG and NOx emissions may exceed the SJVAPCD's annual significance threshold, the Project may impede the implementation of the State air quality attainment plans. Alternative D would results in a **significant** impact.

Mitigation Measure AQ-2 (Alternative D): ***Reduce or Offset Project Emissions.*** Refer to Mitigation Measure AQ-2 (Alternative A). The same measure would be used here.

This mitigation measure would reduce criteria exhaust emissions from construction equipment and material hauling vehicles and would offset project construction emissions through a SJVAPCD Voluntary Emission Reduction Agreement. Impacts after mitigation would be **less than significant**.

Impact AQ-3 (Alternative D): ***Expose Sensitive Receptors to Substantial Air Pollutants Associated with Construction***. Compared to the No-Action Alternative, Alternative D would implement the Project and there would be short-term construction activities in the Project area. Construction emissions were estimated for the off-road construction equipment and material hauling vehicles which are diesel fueled. These diesel fueled equipment emit the toxic air contaminant diesel particulate matter. The emissions were estimated and along with air dispersion modeling the concentration in the air was estimated. An exposure assessment and health risk assessment was conducted for sensitive receptors in the Project area. The anticipated health impact for excess cancer risk and chronic hazard index are shown in Table 4-9. The threshold of significance is an increase in excess cancer risk greater than 10 in a million or a chronic hazard index greater than 1.

Sensitive receptors are projected to have an increase in the excess cancer risk for both a resident child and school child exposure scenario. The resident child is located along San Mateo Avenue which sees a significant amount of material hauling emissions as well as being located near construction work areas. The school child is at Washington Elementary and is exposed to material hauling emissions and construction work areas. There is not anticipated to be any non-cancer health effects since the chronic hazard index is less than 1. However, the health risk assessment indicates an increase in cancer risk above the threshold of 10 in a million for sensitive receptors.

When comparing Alternative D to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative D to the No-Action Alternative). Given the results of the health risk assessment which indicate that sensitive receptors would have an increase in excess cancer risk above the threshold of 10 in a million, the impact would be **significant**.

Mitigation Measure AQ-3A (Alternative D): ***Reduce Diesel Particulate Matter Emissions from Construction Equipment.*** Refer to Mitigation Measure AQ-3A (Alternative A). The same measure would be used here. All off-road construction diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices.

Mitigation Measure AQ-3B (Alternative D): ***Reduce Diesel Particulate Matter Emissions from Material Hauling Vehicles.*** Refer to Mitigation Measure AQ-3B (Alternative A). The same measure would be used here. Material hauling trips will be consolidated into the fewest trips possible. All material hauling diesel equipment will use the cleanest reasonably available equipment or consider alternative fueled equipment or addition of after-market control devices.

If it is assumed that mitigation measures AQ-3A and AQ-3B could mitigate emissions by 85 percent which is the maximum estimated if diesel particulate filters can be used by all equipment and trucks, the risk associated with Alternative D would be reduced to 16.65 in a million for the resident child. The excess cancer risk would still be above 10 in a million. This is due to the size of the construction project and the receptors' close proximity to the roadway. Alternative D after mitigation would still have a substantial effect on exposure of sensitive receptors to health impacts. After mitigation, Alternative D impacts would remain **significant and unavoidable** in exposing sensitive receptors to substantial air pollutants.

Impact AQ-4 (Alternative D): ***Create Excess Amounts of Operational Related Criteria Air Pollutants that Exceed SJVAPCD Thresholds of Significance or Cause or Contribute to Exceedances of the AAQS***. Compared to the No-Action Alternative, Alternative A would implement the Project and there would be some operational activities in the Project area. Operation emissions are estimated to be from workers driving to the Project area to do routine maintenance and operation activities associated with the water control structures. There are no other sources of emissions anticipated with operation of the Project. These emissions were quantified based on the anticipated number of worker trips. The operational emissions are shown in Table 4-10. These operational emissions were compared to the SJVAPCD's significance thresholds and the General Conformity Rule *de minimis* thresholds. The operational emissions do not exceed these thresholds.

Alternative D would also convert active agricultural areas to natural areas and open space reducing agricultural emissions in the Project area. Agricultural field operations, such as tilling, planting, weeding, fertilizing, harvesting, and spreading of manure or compost can produce air pollution emissions from the mechanical movement of soil or from engine operation and fuel combustion.

When comparing Alternative D to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative D to the No-Action Alternative). Therefore, the operational related criteria air pollutants would result in a **less than significant** impact.

Impact AQ-5 (Alternative D): ***Expose Sensitive Receptors to Substantial Air Pollutants Associated with Operation***. Compared to the No-Action Alternative, Alternative D would implement the Project and there would be operational activities in the Project area. Operational activities would be associated with workers driving to the site to perform routine maintenance and operation activities associated with the water control structures. Most of these vehicles would be gasoline fueled and the gasoline exhaust has significantly less toxicity compared to diesel exhaust. The number of additional trips added to the area near sensitive receptors is minimal. Therefore, there would not be a substantial source of operational related toxic air contaminants.

When comparing Alternative D to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative D to the No-

Action Alternative). As a result, there would be a **less than significant** impact on sensitive receptors due to toxic air contaminants from Project operation of Alternative D.

Impact AQ-6 (Alternative D): ***Create Objectionable Odors from Construction.*** Compared to the No-Action Alternative, Alternative D would implement the Project and there would be construction activities in the Project area. Construction equipment and material hauling vehicles using diesel fuel may emit objectionable odors associated with combustion of the diesel fuel. However, these emissions would be transitory.

When comparing Alternative D to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative D to the No-Action Alternative). Therefore, odor impacts of Alternative D associated with diesel combustion during construction activities would be a **less than significant** impact from odors.

Impact AQ-7 (Alternative D): ***Create Objectionable Odors from Operation.*** Compared to the No-Action Alternative, Alternative D would implement the Project and there would be operational activities in the Project area. The operational activities are associated with workers commuting to the Project area to perform routine operation and maintenance. The worker vehicles are not expected to noticeably increase the amount of odors associated with traffic along roads in the Project area.

When comparing Alternative D to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative D to the No-Action Alternative). Therefore, odor impacts of Alternative D associated with operational activities would result in a **less than significant** impact.

5.0 Biological Resources – Fisheries

This section describes the fisheries within the Project area, including habitats, species, and special-status fish species. Section 5.1 describes the environmental setting and Project boundaries. Section 5.2 describes the regulations and local ordinances that would apply to aquatic wildlife resources. Section 5.3 discusses environmental consequences and mitigation measures, where needed.

5.1 Environmental Setting

The environmental setting focuses on Reach 2B, a section of the San Joaquin River which begins at the Chowchilla Bifurcation Structure and ends at Mendota Dam. The Project area also includes about 1,800 linear feet of river upstream of the Chowchilla Bifurcation Structure, about 1.7 miles of the river downstream of Mendota Dam, and a portion of Fresno Slough.

Existing conditions are defined as the conditions existing when the Notice of Intent and Notice of Preparation were filed, which was July 2009, prior to the start of Interim Flows. Several field efforts occurred at later dates, and therefore, the best available information to describe existing conditions also includes information from the period after the start of Interim Flows.

5.1.1 Aquatic Habitat

Mendota Pool is located at the confluence of Fresno Slough and the San Joaquin River. The San Joaquin River arm of Mendota Pool extends from Mendota Dam to San Mateo Avenue. San Mateo Avenue has a low-flow crossing consisting of a culvert and an earthen embankment supporting the roadbed which is overtopped during higher flows.

Water is typically delivered to Mendota Pool from the Delta-Mendota Canal (DMC) and is withdrawn at several canal or pump locations in the Pool including Columbia Canal, Helm Ditch, Main Canal, Outside Canal, Fresno County Waterworks District Canal, Mowry pumps, and others. Water is also delivered to the Pool by the Mendota Pool Pumpers group as well as by river flows. Mendota Pool has been dewatered biennially in mid-winter for inspections and maintenance of the dam, but some locations held standing water during this several week period. Although recent repairs at Mendota Dam have reduced the need to dewater the Pool for dam inspections, Mendota Pool was most recently dewatered for maintenance in the winter of 2011 to 2012.

Prior to the start of Interim Flows in October 2009, the section of Reach 2B between the Chowchilla Bifurcation Structure and San Mateo Avenue was mostly dry (San Joaquin River Restoration Program [SJRRP] 2010a). Surface flows throughout Reach 2B occurred during very wet periods (about every 3 to 5 years). Water released from

Mendota Dam was typically delivered to downstream water users. Downstream of the last diversion point, the river was typically dry.

Aquatic habitat in Reach 2B was either mostly absent within the dry section of the channel or was backwatered in the impounded water body. The river channel was composed of a sand bed with margins occupied by sparse riparian or ruderal vegetation (SJRRP 2010b). The portion of the Reach 2B channel upstream of San Mateo Avenue was composed of unconsolidated fine sand. Aquatic habitat was seasonal because flow was not sustained in the channel. The channel bed was generally devoid of a defined low-flow channel or aquatic habitat features such as pools and bars. Riparian vegetation was sparse and limited to the levees along the channel. Downstream of San Mateo Avenue, aquatic habitat was affected by the backwatering of Mendota Dam and sedimentation in Mendota Pool. The channel was defined by emergent, wetland, and riparian vegetation, including mature cottonwood trees, established along the backwatered portion of Mendota Pool. Most of the Pool was fairly shallow, and some areas also contained submerged aquatic vegetation. Mendota Pool contained mostly introduced fish and a few native fish.

Since the start of Interim Flows there have been some changes in Reach 2B, mostly between the Chowchilla Bifurcation Structure and San Mateo Avenue. The changes primarily consist of more regular inundation due to increased water releases from Friant Dam and the associated establishment of hydrophilic vegetation. Aquatic habitat includes a series of low gradient riffles, flatwater glides, and mid-channel pools (California Department of Fish and Wildlife [DFW] 2010). However, in dry years, portions of the channel still experience extended periods of desiccation. The section of Reach 2B affected by backwater is visibly unchanged by Interim Flows and generally persists as described above because it continues to have water year-round.

5.1.2 Aquatic Foodweb

The aquatic food web is poorly understood and documented in Reach 2B. However, what has been documented are modifications to habitat, introduction of nonnative species, water management activities, and alteration of water quality, which has substantially altered nutrient processing by the primary producers (diatoms and aquatic vegetation) and secondary producers (zooplankton and aquatic invertebrates), and has affected fish communities and other aquatic fauna (Brown 1996).

Food web processes in Reach 2B are influenced by invertebrate production within the reach and by the drift of benthic invertebrates into and out of the reach. The quantity of insects that would drift during times of flow into Reach 2B from upstream reaches is unknown. Reach 1 has gravel substrates and riffles which create productive habitat for benthic invertebrates, suggesting that many prey taxa are likely available for juvenile salmonids[1] (Stillwater Sciences 2003). While many of these taxa have high propensity to drift and are likely important components of fish diets, how far they drift and whether they would drift to locations downstream that do not retain gravel substrate (such as Reach 2B) is unknown. The amount of insect drift that enters Reach 2B would be

[1] Salmonids are those fishes from the *Salmonidae* family, such as salmon, trout, and char.

affected by flows directed into Chowchilla Bypass at the Chowchilla Bifurcation Structure. The amount of insect drift from Reach 2B to downstream reaches would be affected by the proportion of inflow that is exported out of Mendota Pool. Mendota Pool habitat and food web processes would also be affected by water that is imported through the DMC and groundwater inputs from the Mendota Pool Pumpers.

Floodplains that support riparian vegetation or grasslands that are seasonally inundated can also provide a source of nutrients and primary and secondary producers that can propagate to downstream channels, if not exported at on-river diversions. Floodplain habitats typically produce small invertebrates with short life cycles, such as chironomids and cladocerans (McBain and Trush 2002). The inundation timing, duration, and frequency of inundation influence invertebrate production and nutrient processing on floodplains (Ahearn et al. 2006; Grosholz and Gallo 2006). This resource availability, combined with warmer temperatures on the floodplains compared to main channel habitats, has been documented to accelerate juvenile salmonid growth in floodplain river systems (Jeffres et al. 2008). Under existing conditions, however, there is only the main river channel and very limited floodplain habitat is present between the existing levees in Reach 2B.

Invasive fish species may alter food webs and have adverse consequences to native fish species, including increased competition for resources, direct predation, and habitat or behavior interference (Moyle 2002). San Joaquin River non-native piscivores include largemouth bass (*Micropterus salmoides*), smallmouth bass (*Micropterus dolomieu*), green sunfish (*Lepomis cyanellus*), warmouth (*Lepomis gulosus*), black crappie (*Pomoxis nigromaculatus*), striped bass (*Morone saxatilis*), brook trout (*Salvelinus fontinalis*), redear sunfish (*Lepomis microlophus*), spotted bass (*Micropterus punctulatus*), channel catfish (*Ictalurus punctatus*), and white catfish (*Ameiurus catus*). Because of their small size and weaker swimming abilities, larval and early life stages of fish are particularly vulnerable to predation. Imported water from the DMC is an ongoing source for some of these species. Millerton Reservoir and Fresno Slough can also be sources of nonnative fish species.

5.1.3 Aquatic Species Known to Occur in the Project Area and Vicinity

Table 5-1 provides a list of fish species captured and reported between Reaches 2A and 3. Many of these species were found in Mendota Pool.

Table 5-1.
Fish Species in the Vicinity of Reach 2B

Native Fish Species	
Hitch (*Lavinia exilicauda*) [*,1, 3]	Sacramento sucker (*Catostomus occidentalis*) [*,1, 2, 3]
Tule perch (*Hysterocarpus traskii*) [3]	Sacramento splittail (*Pogonichthys macrolepidotus*) [*, 2]
River lamprey (*Lampetra ayresi*) [3]	Prickly sculpin (*Cottus asper*) [2, 3]
Sacramento blackfish (*Orthodon microlepidotus*) [3]	Rainbow trout (*Oncorhynchus mykiss*) [2, 3]
Hardhead (*Mylopharodon conocephalus*) [3]	Sacramento pikeminnow (*Ptychocheilus grandis*) [2, 3]
Kern Brook lamprey (*Lampetra hubbsi*) [3]	Chinook salmon (*Oncorhynchus tshawytscha*) [2]

Table 5-1.
Fish Species in the Vicinity of Reach 2B

Pacific lamprey (*Lampetra tridentata*) [3]	Riffle sculpin (*Cottus gulosus*) [2]
Threespine stickleback (*Gasterosteus aculeatus*) [2, 3]	
Introduced Fish Species	
Threadfin shad (*Dorosoma petenense*) [*,1, 2, 3]	Black bullhead (*Ameiurus melas*) [*,1, 2, 3]
Black crappie (*Pomoxis nigromaculatus*) [*,1, 2, 3]	Largemouth bass (*Micropterus salmoides*) [*,1, 2, 3]
Inland silverside (*Menidia beryllina*) [*, 1, 2, 3]	White catfish (*Ameiurus catus*) [*,1, 2, 3]
Striped bass (*Morone saxatilis*) [*,1, 2, 3]	Pumpkinseed (*Lepomis gibbosus*) [*,1, 2, 3]
Channel catfish (*Ictalurus punctatus*) [*,1, 2, 3]	American shad (*Alosa sapidissima*) [*,1]
Bluegill (*Lepomis macrochirus*) [*,1, 2, 3]	Warmouth (*Lepomis gulosus*) [*,1, 2, 3]
White crappie (*Pomoxis annularis*) [*,1, 2, 3]	Golden shiner (*Notemigonus crysoleucas*) [*,1, 2, 3]
Goldfish (*Carassius auratus*) [*,1,2,3]	Brown bullhead (*Ameiurus nebulosus*) [*,1,2, 3]
Common carp (*Cyprinus carpio*) [*,1, 2, 3]	Western mosquitofish (*Gambusia affinis*) [*,1, 2, 3]
Green sunfish (*Lepomis cyanellus*) [*,1, 2, 3]	Bigscale logperch (*Percina macrolepida*) [*,1, 2, 3]
Redear sunfish (*Lepomis microlophus*) [*, 2, 3]	Red shiner (*Cyprinella letrensis*) [*, 2, 3]
Black bass spp. (*Micropterus spp.*) [*, 2]	Fathead minnow (*Pimephales promelas*) [*, 2, 3]
Spotted bass (*Micropterus punctulatus*) [*, 2, 3]	Yellow bullhead (*Ameiurus natalis*) [*, 2]
Shimofuri goby (*Tridentiger bifasciatus*) [*, 2, 3]	Weather loach (*Misgurnus anquillicaudatus*) [*]
Redeye bass (*Micropterus coosae*) [3]	

Notes:

* Fish species that are also found in Reaches 2A and/or 3

[1] Jones and Stokes 1986, Scientific and common names have been updated from Jones and Stokes (1986) to be consistent with current nomenclature (Nelson et al. 2004).

[2] Hutcherson 2013, unpublished data.

[3] Workman and Portz 2013.

Several fish surveys have been conducted in the San Joaquin River or in the major tributaries of the San Joaquin Valley. Jones and Stokes (1986) found two native fish species (hitch [*Lavinia exilicauda*] and Sacramento sucker [*Catostomus occidentalis*]) and 20 introduced species in Mendota Pool. Since the 1986 survey, additional introduced species have appeared in the Delta and are likely to have been transported to Mendota Pool causing species composition shifts. Previously unreported species were found during surveys of Reaches 1, 3, and 5 during 2004 and 2005. The number of species typically found increased with distance downstream from Friant Dam and the composition of fish assemblages shifted from native species to non-native species.

USFWS and Reclamation conducted comprehensive fish surveys in the San Joaquin River in 2012 and 2013, after the start of Interim Flows. These surveys have found previously unreported native and introduced fish species between Reach 2A and Reach 3. Native fish species captured include Pacific lamprey (*Lampetra tridentate*), prickly sculpin (*Cottus asper*), Sacramento splittail (*Pogonichthys macrolepidotus*), Sacramento blackfish (*Orthodon microlepidotus*), hardhead (*Mylopharodon conocephalus*), Kern Brook lamprey (*Lampetra hubbsi*), river lamprey (*Lampetra ayresi*), and tule perch

(*Hysterocarpus traskii*). Introduced species captured include redear sunfish, spotted bass, Shimofuri goby (*Tridentiger bifasciatus*), bigscale logperch (*Percina macrolepida*), redeye bass (*Micropterus coosae*), striped bass, red shiner (*Cyprinella letrensis*), fathead minnow (*Pimephales promelas*), and yellow bullhead (*Ameiurus natalis*) (Hutcherson 2013; Workman and Portz 2013). Pacific staghorn sculpin (*Leptocottus armatus*) and brook trout (*Salvelinus fontinalis*) have also been detected between Reach 2A and Reach 3. They were likely introduced as a result of the Delta-Mendota Canal and upstream hatcheries, respectively, but these species would be unable to complete their life cycle in Reach 2B and therefore should not be considered part of the Reach 2B fish community. Reaches 1 and 3 and Mendota Pool have likely been sources of fishes that colonize Reach 2B as flows have been restored to the San Joaquin River.

On October 6, 2014 during a 2014 fish sampling effort just upstream of the Chowchilla Bifurcation Structure in Reach 2A (River Mile 215 to 218), U.S. Fish and Wildlife Service (USFWS) captured a weather loach (*Misgurnus anquillicaudatus*), a previously undocumented nonnative species (SJRRP 2014; USFWS 2014). USFWS and CDFW conducted a more intensive fish sampling effort on November 12, 2014 (USFWS 2014). Six additional weather loaches were captured upstream of the structure while none were detected downstream of the structure. Possible negative effects of this species could include egg predation, competition, and pathogen transfer.

Fall-run Chinook salmon (*Oncorhynchus tshawytscha*) have occasionally been found moving into the San Joaquin River upstream of the Merced River (San Francisco Estuary Institute [SFEI] 2002). Although the Hills Ferry Barrier is seasonally installed to restrict movement of adult salmon into areas that presently do not provide access to spawning habitat, adult fall-run Chinook salmon have been observed upstream of the Hills Ferry Barrier and have been observed in wet years at the base of Mendota Dam (Portz et al. 2011).

Although anglers have reported catching 69 white sturgeon (*Acipenser transmontanus*) and one green sturgeon (*Acipenser medirostris*) downstream of the Project area between 2007 and 2012 (DFW 2012), there have been no documented capture of white or green sturgeon from Reach 2B. USFWS captured 28 subadult/adult white sturgeon from 2012 to 2013 and documented spawning at four locations between Vernalis and Grayson (Jackson and Van Eenennaam 2013), approximately 116 to 133 river miles downstream of Reach 2B.

5.1.4 Special Status Species

Based on records in the California Natural Diversity Database (CNDDB) (DFW 2015) and USFWS lists for the Bonita Ranch, Coit Ranch, Firebaugh, Firebaugh NE, Gravelly Ford, Jamesan, Mendota Dam, Poso Farm, and Tranquility U.S. Geological Survey (USGS) 7.5-minute quadrangles (USFWS 2015), three special-status fish species are discussed as to whether they are potentially present in the vicinity of Reach 2B (Table 5-2). Special-status fish species include those species that are Federally-listed, proposed for Federal listing, Federal candidate species, State listed, State fully protected species, or species of special concern.

Table 5-2.
Threatened or Endangered Fish Species, Associated Critical Habitat, or Essential Fish Habitat Considered as Potentially Occurring Within the Project Area

Scientific Name	Common Name	Status	Critical Habitat or Essential Fish Habitat in or near Project Area
Hypomesus transpacificus	Delta Smelt	SE, FT	No
Oncorhynchus mykiss	Central Valley steelhead	ST, FT	No
Oncorhynchus tshawytscha	Central Valley Fall-run and Late fall-run Chinook salmon	SSC	Yes, Essential Fish Habitat
Oncorhynchus tshawytscha	Central Valley Spring-run Chinook salmon[1]	FT	Yes, Essential Fish Habitat

Note:
[1] A nonessential experimental population of spring-run Chinook salmon was released into the Restoration Area in spring 2014. Members of the experimental population have special regulations written for them under Section 4(d).
Key:
FT = Federally Threatened
SE = State of California Endangered
ST = State of California Threatened
SSC = species of special concern

The Federal Endangered Species Act of 1973 (ESA) requires that USFWS and National Oceanic and Atmospheric Administration (NOAA) National Marine Fisheries Service (NMFS) designate critical habitat for the listed species they manage. Federal agencies are required to consider the potential effects of their actions, including permit approval or funding, on listed species and their critical habitat.[2] Critical habitat has been designated for Delta smelt (*Hypomesus transpacificus*) and Central Valley steelhead (*Oncorhynchus mykiss*), but it does not occur within the Project area.

Essential fish habitat (EFH) for Chinook salmon has been designated in the Sacramento and San Joaquin River basins, including the Project area and vicinity. EFH is defined as those waters and substrates necessary to fish for spawning, breeding, feeding, or growth to maturity. Chinook salmon stocks with potential to occur in Reach 2B include Central Valley fall-run and late fall-run Chinook salmon and a nonessential experimental population of Central Valley spring-run Chinook salmon (Table 5-2). Federal fishery management plans identify EFH, as required by the Magnuson-Stevens Fishery Conservation and Management Act (MSFCMA). The Pacific Coast Salmon Fishery Management Plan (Pacific Fishery Management Council [PFMC] 2012) identifies and protects habitat for Pacific coast salmonid species. Although the Central Valley fall-run and late fall-run Chinook salmon are not considered threatened or endangered under the ESA, the habitat is protected as EFH under the MSFCMA.

[2] The ESA defines critical habitat as "the specific areas within the geographical area occupied by the species, at the time it is listed, on which are found those physical or biological features (I) essential to the conservation of the species and (II) which may require special management considerations or protection; and specific areas outside the geographical area occupied by the species at the time it is listed that are determined by the Secretary of the Interior to be essential for the conservation of the species."

Delta Smelt

Species Description

Delta smelt are slender bodied fish about 2 to 3 inches long, in the Osmeridae family (smelts). The species is endemic to the Sacramento-San Joaquin Delta. Delta smelt are able to live in waters with a wide range of salinity and typically rear in shallow (< 10 feet), open waters of the estuary (Moyle 2002). They are mostly found within a salinity range of 2 to 7 parts per thousand and have been collected from the estuarine waters up to 14 parts per thousand. This species can be found in the Delta nearly year-round, with adults moving into the interior Delta before spawning, beginning in December. Spawning occurs from February through May with larval and juvenile fish developing during spring and summer.

USFWS has defined four constituent elements of delta smelt habitat, including: (1) shallow freshwater to slightly brackish sites for spawning; (2) protected channels and rivers to provide transport of larvae to downstream rearing sites; (3) estuary rearing habitat that provides a shallow, protective, food-rich environment; and (4) unrestricted access to spawning sites between December and July (USFWS 1994).

Known Occurrences

CNDDB describes no known occurrences within 10 miles of the Project footprint; in fact, the Project area is over 100 miles from the nearest occupied delta smelt habitat. Delta smelt have been found in the San Joaquin River as far upstream as Mossdale and above, but still within the legal boundaries of the Delta (over 100 river miles below Reach 2B). Delta smelt could be found in Mendota Pool since water from the Delta is pumped into the DMC, but the likelihood of delta smelt surviving the trip in the canal system is very low. Delta smelt reaching the Mendota Pool would be unlikely to survive because of unsuitable habitat that does not provide food resources that smelt depend on for survival and because of water temperatures would also be outside the optimal temperature range for delta smelt during late spring through summer. Potential Project-related flow volume, timing, or water quality changes from the San Joaquin River into the Delta that may affect delta smelt was addressed in the Program Environmental Impact Statement/Report (PEIS/R) (SJRRP 2011, pages 5-82 and 5-83). Based on the available data and existing habitat conditions, the potential for delta smelt to occur within the Project area is extremely low.

Central Valley Steelhead

Species Description

Central Valley steelhead Distinct Population Segment consists of naturally spawned anadromous populations of *O. mykiss* downstream of natural and man-made impassable barriers in the Sacramento and San Joaquin rivers and their tributaries. Steelhead can be divided into two life history types, winter (ocean-maturing) and summer (river-maturing), based on their sexual maturity at river entry and the duration of their spawning migration. Only winter run types are presently found within the Central Valley. Two artificial propagation programs are considered part of the Distinct Population Segment: the Coleman National Fish Hatchery and the Feather River Fish Hatchery steelhead hatchery

programs. The San Joaquin Hatchery, located downstream of Friant Dam, rears rainbow trout for planting into Reach 1 and other locations above Millerton Lake in Fresno and Madera counties. The hatchery operations and facilities would be modified as necessary to support restoring runs of salmon to the San Joaquin River (as a separate project with separate environmental compliance documentation).

Central Valley steelhead generally leave the ocean from August through April and move upstream into Central Valley rivers. Spawning takes place from December through April with a peak between January and March. Steelhead are iteroparous (i.e., capable of spawning more than once over several years), so post-spawn adults (i.e., kelts during this life stage) can return to the ocean where they will mature and possibly migrate inland to spawn again. Juvenile steelhead rear in cold water streams in riffles, runs, and pools. Most steelhead will rear for at least a full year before they begin migrating downstream to the ocean. Outmigration occurs when fish reach 6 to 8 inches in size and begin to transform from a resident juvenile form to a smolt. Outmigration can occur from fall through spring with a peak from February through April.

The NMFS has defined six constituent elements of Central Valley steelhead habitat, including: (1) freshwater spawning sites; (2) freshwater rearing sites with sufficient shade, foraging areas, and space for growth and movement; (3) freshwater migration corridors with sufficient areas of cover; (4) estuarine areas that provide areas for foraging and cover; (5) near shore marine areas that allow for juvenile transition from natal streams to offshore environments; and (6) off-shore marine areas with sufficient forage (NMFS 2005).

Known Occurrences

Steelhead or resident rainbow trout have been captured in the three main tributaries of the San Joaquin River including the Stanislaus, Tuolumne and Merced rivers. They are not known to occur in Reach 5 or upstream within the San Joaquin River (Eilers et al. 2010). Since steelhead require year round habitat for juvenile rearing they would not be present in the typically dry sections of Reach 2B. It is possible, but highly unlikely that juvenile steelhead would be present in the Mendota Pool because water from the Delta is delivered to the pool via the DMC. These fish would have had to successfully be passed through Tracy Fish Collection Facility lift pumps and transit through a canal system full of predators. Aquatic habitat in Mendota Pool is unsuitable for steelhead during the warm summer months.

Based on the occurrence data and available information, there is extremely low potential for Central Valley steelhead to be present within the Project area under existing conditions. As flows are restored to the San Joaquin River and fish passage is provided it is likely that steelhead may move upstream and occupy Reach 2B seasonally during times of the year when water temperatures and habitat are suitable. For example, steelhead could reside year round in Reach 1 or use Reach 2B as a migration corridor if they become established in the San Joaquin River.

Central Valley Fall-Run Chinook Salmon

Species Description

Central Valley fall-run Chinook salmon occur in the Sacramento River and its tributaries; the Delta and Suisun Marsh; and the San Joaquin River and five of its east-side tributaries, including the Merced, Tuolumne, Stanislaus, Mokelumne, and Cosumnes rivers. The Central Valley evolutionarily significant unit (ESU) is considered the southernmost native spawning population of Chinook salmon. Fall-run Chinook are currently the most numerous of the Central Valley runs and the only race that regularly spawns in the San Joaquin basin (NMFS 2008).

Fall-run are ocean-type Chinook that tend to enter freshwater as fully mature fish, migrate to lowland reaches of large rivers and tributaries, and spawn within a few days or weeks of arriving on the spawning grounds. Currently, adult fall-run salmon in the San Joaquin River basin typically migrate upstream between mid-September and early December, and spawn between late October and early December in tributaries of the Sacramento and San Joaquin basins (Moyle 2002). Fall-run Chinook salmon typically rear in freshwater for 1 to 3 months before outmigrating to the ocean, but some may disperse downstream as fry soon after emerging from the streambed. Life history requirements for adult and juvenile Chinook salmon are more fully described in the SJRRP *Fisheries Management Plan* (SJRRP 2010c).

Known Occurrences

Fall-run Chinook salmon occur in the Stanislaus, Tuolumne, and Merced Rivers, but no longer occur within the Project area. Historically, the San Joaquin River likely supported relatively few fall-run Chinook salmon after diversions began at Sack Dam, sometime between 1860 and 1880. During all but wet years, the river was nearly completely dewatered downstream from Sack Dam until late November, by which time it was too late for most fall-run Chinook salmon to migrate upstream in the San Joaquin River Basin (SJRRP 2010c). Fall-run Chinook salmon likely used the San Joaquin River system only when flows were sufficient for upstream passage during the fall.

More recently, Chinook salmon have been found in the San Joaquin River in the vicinity of Mud Slough and the confluence of the Merced River. From 2001 to 2009, two adult Chinook salmon were collected from the San Joaquin River in the vicinity of the Merced River; one was collected at Fremont Ford on December 3, 2003, and the other was collected at Hills Ferry, below Mud Slough, on December 5, 2007 (SFEI 2002). An older report from the Grasslands Bypass program covering the period from 1993 to 2002 is referenced in the 2001 to 2002 report; it notes that 26 Chinook salmon were collected, but the data to support these claims were not verifiable (Eacock, pers. comm., 2011).

During the fall of 2010, after large, early storms damaged the Hills Ferry Barrier and allowed salmon to move above the barrier for several days, multiple adult Chinook salmon were observed by DFW biologists below Sack Dam between November 16 and 18, and below Mendota Dam between November 22 and December 8 (Guzman, pers. comm., 2011).

Based on the occurrence data and available information, fall-run Chinook salmon have not typically been present within the Project area prior to SJRRP restoration activities.

The SJRRP has been releasing fall-run Chinook salmon to the San Joaquin River since 2010 to study juvenile outmigration. Beginning in 2012, adult fall-run have been captured above the Hills Ferry Barrier and transported to Reach 1, to either spawn naturally or be spawned artificially, their progeny outmigrating the following winter/spring.

When fish passage and sufficient flows are provided to Sack Dam in Arroyo Canal located in Reach 3, adult fall-run Chinook salmon could migrate upstream through Reach 2B from October through December, and juvenile fish released in Reach 1 could use Reach 2B for migrant rearing from February through May. These young-of-the-year fish would occur in Reach 2B as transient juveniles as they migrate downstream toward the ocean (Stillwater Sciences 2003).

Central Valley Spring-Run Chinook Salmon

Species Description

The Central Valley spring-run Chinook salmon ESU consists primarily of three populations in three tributary systems (Mill, Deer, and Butte creeks), as well as Feather River and Clear Creek, which are all located within the Sacramento River basin. Recent reintroductions have also established a run in Battle Creek. The population uses rearing and migration habitats in the Sacramento River basin and Delta, San Francisco Bay, and offshore ocean waters.

Historically, spring-run salmon in the San Joaquin River migrated upstream between April and early July, with most adults migrating upstream in May and June. Currently, there is no population of spring-run salmon in the San Joaquin River basin.

Spring-run Chinook salmon tend to enter freshwater as immature fish, migrate far upriver, and delay spawning for weeks or months (stream-type life history) (West Coast Chinook Salmon Biological Review Team [WCCSBRT] 1997). Spawning occurs in Sacramento River tributaries from late September through mid-November. Fry emerge from the gravel from November to March and spend about 3 to 15 months in freshwater habitats prior to emigrating to the ocean. Spring-run Chinook salmon generally mature between 2 and 4 years of age.

In addition to rearing in natal streams, spring-run Chinook salmon juveniles rear in the lower part of nonnatal tributaries and intermittent streams during the winter months (Maslin et al. 1997). Emigration can be highly variable. Some juveniles may begin outmigrating soon after emergence, whereas others over-summer and emigrate as yearlings with the onset of intense fall storms (DFW 1998). The emigration period for spring-run Chinook salmon extends from November to early May. Emigration appears to coincide with high precipitation and high Sacramento River flows.

NMFS designated critical habitat for spawning and rearing Central Valley spring-run Chinook salmon in the Sacramento River and specific tributaries, as well as in the Sacramento Delta Hydrologic Unit within the Sacramento-San Joaquin Delta.

Known Occurrences

Spring-run Chinook salmon no longer occur within the Project area. Historically, spring-run Chinook salmon spawned in the San Joaquin River from about the present day location of Friant Dam to as far upstream as Mammoth Pool (River Mile 322) (McBain and Trush 2002). During the late 1930s and early 1940s, as Friant Dam was being constructed, large runs continued to return to the river. After the dam was completed and the reservoir was filling, runs of 30,000 to 50,000 fish continued to return and spawn in the river downstream of Friant Dam. These runs were completely gone by 1950, as diversions from Friant Dam resulted in the river being dry at Gravelly Ford (McBain and Trush 2002).

There have been reports of Chinook salmon with spring-run-like life histories from tributaries of the San Joaquin River and Delta, specifically in the Stanislaus and Mokelumne rivers. Snorkel surveys in the Stanislaus River in the mid-2000s and netting surveys in the early 2000s resulted in observation or capture of adult Chinook salmon from the Stanislaus River in mid-summer (Wikert, pers. comm., 2011). There are reports that adult Chinook salmon exhibiting traits similar to spring-run Chinook have been counted in the Woodbridge Dam fish ladder by the East Bay Municipal Utility District (Wikert, pers. comm., 2011).

Based on the occurrence data and available information, spring-run Chinook salmon were not recently present within the Project area prior to SJRRP restoration activities.

Juvenile spring-run Chinook salmon, as part of an experimental population, were released into the Restoration Area in spring 2014 and spring 2015. This action as well as all other Chinook salmon reintroduction actions are analyzed under separate environmental documentation. If successful migration, holding, and spawning occurs, juvenile fish could be found using Reach 2B for migrant rearing from November through May. When migration flows are restored to the San Joaquin River and fish passage is provided, adult spring-run Chinook salmon from other rivers in the Central Valley may stray into the San Joaquin River during winter or spring.

5.2 Regulatory Setting

The Federal, State, and local laws and regulations applicable to fisheries in the Project area are described below.

5.2.1 Federal

The following subsections describe Federal laws and regulations governing the protection of fisheries resources.

Clean Water Act Sections 401 and 404

(See Chapter 14.0, “Hydrology - Surface Water Resources and Water Quality.”)

Rivers and Harbors Act Section 10

(See Chapter 14.0, “Hydrology - Surface Water Resources and Water Quality.”)

Federal Endangered Species Act of 1973 (16 United States Code [USC] Section 1531 et seq., 50 Code of Federal Regulations [CFR] Parts 17 and 222)

The ESA includes provisions for protection and management of species that are Federally-listed as threatened or endangered and designates critical habitat for these species. This law prohibits "take" of Federally-listed species, except as authorized under an incidental take permit or incidental take statement. USFWS is the administering agency for this authority for freshwater species. NMFS is the administering agency for anadromous species.

Section 4(d) of the Act allows USFWS or NMFS to establish special regulations for threatened species, subspecies, and Distinct Population Segments. These "4(d) rules" may either increase or decrease ESA's normal protections. One use of 4(d) rules is to relax normal ESA restrictions to reduce conflicts between people and the protections provided to the threatened species. This may occur in situations where conflicts would adversely affect recovery and the reduced protection would not slow the species' recovery.

Section 10(j) of the Act provides for the designation of specific reintroduced populations of listed species as "experimental populations." An experimental population is a geographically described group of reintroduced plants or animals that is isolated from other existing populations of the species. Members of the experimental population are considered to be threatened under ESA, and can have special regulations written for them under Section 4(d).

Fish and Wildlife Coordination Act

The Fish and Wildlife Coordination Act (FWCA) (16 USC 661 et seq.) amended 1946, 1958, 1978, and 1995 requires Federal agencies to coordinate with USFWS, or, in some instances, with NMFS, and with State fish and wildlife resource agencies before undertaking or approving water projects that control or modify surface water. The purpose of this coordination is to ensure that wildlife resources held in public trust receive appropriate consideration and be coordinated with the features of these water resource development projects. Federal agencies undertaking water projects are required to fully consider recommendations made by USFWS, NMFS, and State fish and wildlife resource agencies in project reports, such as documents prepared to comply with the National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA), and to include measures to reduce impacts on wildlife in project plans.

Magnuson-Stevens Fishery Conservation and Management Act 1996 (Public Law 94-265)

This law provides for the conservation and management of all fish resources within the exclusive economic zone of the U.S. and supports and encourages the implementation and enforcement of international fisheries agreements for the conservation and management of highly migratory species. It called for the establishment of Regional Fisheries Management Councils to develop, implement, monitor, and revise fish management plans to promote domestic commercial and recreational fishing. Specifically to the SJRRP, it calls for the protection of EFH in review of projects conducted under Federal permits, licenses, or other authorities that affect or have the potential to affect such habitat. NMFS is responsible for the administration of this act.

Central Valley Project Improvement Act

Implementation of the Central Valley Project Improvement Act (CVPIA) changed management of the Central Valley Project (CVP) by making fish and wildlife protection a project purpose, equal to water supply for agricultural and urban uses. The CVPIA affects water exports from the Delta to San Luis Reservoir and increases operational pressures on the reservoir to meet south-of-Delta water demands. CVPIA Section 3406 (b)(2) authorized and directed the Secretary of the Interior, among other actions, to dedicate and manage 800 thousand acre-feet (TAF) of CVP yield annually for the primary purpose of implementing the fish, wildlife, and habitat restoration purposes and measures authorized in the CVPIA; assist the State in its efforts to protect the waters of the San Francisco Bay-Delta Estuary; and help meet obligations legally imposed on the CVP under Federal or State law following the date of enactment of the CVPIA. CVPIA Section 3406(d)(1) required that the Secretary of the Interior immediately provide specific quantities of water to the refuges, referred to as "Level 2" supplies. The CVPIA requires delivery of Level 2 water in all year–types except critically dry water year conditions, when Level 2 water can be reduced by 25 percent. Section 3406(d)(2) of the CVPIA refers to "Level 4" refuge water supplies, which are the quantities required for optimum habitat management of the existing refuge lands. Level 4 water supplies amount to about 163 TAF above Level 2 water supplies. The availability of Level 4 refuge water supplies is influenced by the availability of water for transfer from willing sellers. CVPIA Section 3406(c)(1) mandated development of a comprehensive plan that is reasonably prudent and feasible to be presented to Congress to address fish, wildlife, and habitat concerns on the San Joaquin River. However, Public Law 111-11 declared "that the Settlement satisfies and discharges all of the obligations of the Secretary contained in section 3406(c)(1)."

5.2.2 State of California

California Water Code

The California Water Code authorizes the State Water Resources Control Board (SWRCB) to allocate surface water rights and permit diversion and use of water throughout the State. SWRCB considers effects on fisheries as part of its permitting process. Division 7 of the California Water Code, known as the Porter-Cologne Water Quality Control Act, regulates activities that affect water quality.

California Fish and Game Code section 1600 et seq.

This law provides for the protection and conservation of fish and wildlife resources with respect to any project that may substantially divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of any river, stream, or lake. The administering agency is the DFW.

California Endangered Species Act of 1984 (Fish & G. Code, §§ 2050-2098)

This law provides for the protection and management of species and subspecies listed by the State as endangered or threatened, or designated as candidates for such listing. They are listed at California Code of Regulations, Title 14, section 670.5. This law prohibits "take" of state-listed or candidate species, except as otherwise authorized by the Fish and Game Code. The term "take" is defined by Fish and Game Code section 86 as "hunt,

pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill." This definition is different in some respects from the definition of "take" under the ESA. The administering agency is the DFW.

Sufficient Water for Fish Below Dams (Fish & G. Code, § 5937)

This law requires that an owner or operator of a dam allow sufficient water to pass through a fishway, or, in the absence of a fishway, allow sufficient water to pass over, around, or through the dam to keep fish in good condition, whether they are planted or exist below the dam. This law provides exceptions for the owner/operator to pass water through a culvert or waste gate during low flow years when the DFW determines that it is infeasible to pass water through a fishway.

California Freshwater Sport Fishing Regulations 2014-2015, effective March 1, 2014

Fishing gear, methods, limits and the kinds of fish allowed for sport harvest are defined in California Sport Fishing Regulations and are updated by recommendations made by the Fish and Game Commission to the DFW. These regulations (identified in Cal. Code Regs. tit. 14) are enforced by DFW in the field. The regulations cover activities allowed under a sport fishing license by fishing districts and are used to manage the harvest of game fish under General Regulations.

Trout, Salmon and Special Regulations, District General Regulations (Cal. Code Regs., tit. 14., ch. 3, art. 2, §7)

The fishing regulations define which waters and when those waters are open and closed to trout and salmon fishing. The regulations further describe gear restrictions, which other species may be taken, and daily bag and possession limits for each species. In waters where the bag limit for trout or salmon is zero, fish must be released unharmed and should not be removed from the water. The following regulations are applicable to the Valley District.

- All lakes and reservoirs except those listed by name in the Special Regulations. Season – All Year. Bag Limit: five.
- All anadromous waters except those listed by name in the Special Regulations. Season – All Year. Bag Limit: two hatchery trout or hatchery steelhead (four hatchery trout or hatchery steelhead in possession). Closed to the take of salmon.
- San Joaquin River from Friant Dam downstream to the Highway 140 bridge. Season – All Year. Bag Limit: two hatchery trout or hatchery steelhead (four hatchery trout or hatchery steelhead in possession).

Reach 2B is in the Valley District and is an anadromous waterbody. [3] Under existing fishing regulations, Valley District anadromous waters are closed to salmon fishing (i.e., no take or possession of salmon).

[3] Anadromous waters are inland waters that are accessible to fish migrating from the ocean.

Taking Fish near Dams, Fishways, Screens and Egg-Taking Stations (Cal. Code Regs., tit. 14., ch. 3, art. 2, § 2.35)

The fishing regulations also define fishing methods and gear restrictions that may be applicable to conditions found in all fishing districts. A regulation that restricts fishing from dams or fishways would be application to Reach 2B. No fish may be taken within 250 feet of:

- Any fishway or any egg-taking station.
- Any dam or any weir or rack which has a fishway or an egg-taking station.
- The upstream side of any fish screen.

Fish may be taken upstream or downstream from any dam that does not have a fishway or egg-taking station (this supersedes Fish & G. Code, § 5502).

5.2.3 Regional and Local

Fresno County Plans and Ordinances

County ordinances directed at maintaining safety for boating and reducing risks from people attempting to swim from, use or fish off of bridges or water control structures include the following:

- **13.32.041 - Restricted areas for mooring, fishing or operating a vessel or watercraft in an area designated by a regulation marker.** It is unlawful for any person or persons to moor, fish or operate any vessel or watercraft in an area in a lake, river or other body of water designated by a regulation marker placed in the water by any public agency to restrict or control the area designated.
- **13.32.055 - Bridge or water control structure—Certain acts upon prohibited.** It is unlawful to loiter upon, fish upon, or jump from any bridge or water control structure that crosses any river, lake, or canal in the County of Fresno. As used in this section, "water control structure" includes any dams, weirs, control gates or headgates that are used for controlling or diverting the water flow on the various waterways in the County of Fresno.

Madera County Plans and Ordinances

County General Plan policies are directed at maintaining recreational and natural resources within the county. Madera County ordinances are directed at maintaining safety for boating and reducing risks from people swimming in waters where motorized boating occurs. There are no county ordinances covering activities in the San Joaquin River. General Plan policies under Section 5, Agricultural and Natural Resources, include:

- Policy 5.C.8. The County shall support the policies of the San Joaquin River Parkway Plan to protect the San Joaquin River as an aquatic habitat and water source.
- Policy 5.E.7. The County shall support the preservation and reestablishment of fisheries in the rivers and streams within the county, whenever possible.

5.3 Environmental Consequences and Mitigation Measures

5.3.1 Impact Assessment Methodology

This section describes the impact assessment methodology for fisheries resources in the Project area. The qualitative impact assessment relied upon knowledge of aquatic resource habitat requirements and expected changes to habitat or populations under the Project alternatives.

The *Fisheries Management Plan* (SJRRP 2010c) describes how the SJRRP would adaptively manage efforts to restore and maintain naturally reproducing and self-sustaining populations of Chinook salmon and other fish in the Restoration Area. A key objective of the Project would be to support restoring and maintaining populations of salmon and other fish in the San Joaquin River by increasing flow capacity and providing habitat in Reach 2B, a portion of which has been mostly dry prior to implementation of the Interim Flows. There is no spawning habitat contained within Reach 2B. Juvenile rearing habitat would occur during the outmigration period only.

The assessment of effects on fisheries is based on changes to habitat conditions in the channel and on the floodplain compared to existing conditions and the No-Action Alternative. The assessment also includes an evaluation of fish passage conditions at proposed facilities and an evaluation of fish entrainment at proposed screening systems. Fish passage and screening facilities were evaluated with respect to the risk in creating potential predator sites for target species. The assessment includes effects of proposed construction activities and operations on fish species compared to existing conditions and the No-Action Alternative.

Channel Habitat

Channel habitat conditions in Reach 2B are linked to features such as pools, bars, and the amount of bordering riparian habitat. These conditions would be expected to change somewhat in the Reach 2B upstream of Mendota Pool; however, the amount and nature of the habitat change are not quantifiable. Channel habitat was evaluated by comparing the relative amount of levee disturbance and channel and floodplain connection for each Project alternative.

Floodplain Habitat

Floodplain habitat for rearing juvenile fish was assessed by evaluating the amount of direct and indirect rearing habitat for the Project alternatives. For the purpose of this analysis, direct rearing habitat is defined as acres of floodplain with a depth greater than 1.0 feet at 2,500 cubic feet per second (cfs), while indirect rearing habitat is defined as the acres of floodplain with a depth less than 1.0 feet at 2,500 cfs. [4] Indirect rearing habitat was evaluated as a proportion of the amount of very shallow water habitat to the amount of rearing habitat.

[4] Direct rearing habitat refers to the habitat areas that fish physically occupy for rearing. Indirect rearing habitat refers to the habitat areas that fish do not physically occupy, but that do provide food and nutrient resources used by rearing fish. Indirect rearing habitat is also known as primary production habitat.

Fish Passage

Fish passage facilities would be provided at existing or proposed structures that would otherwise prevent or impede up- and down-stream passage of migratory salmon and other native fishes. The fish passage assessment assumed that all proposed structures would meet fish passage criteria established by fisheries agencies (see Section 2.2.4); as a result, the impact assessment is qualitative and based on the total number of artificial structures in the migratory pathway. Each structure, whether it is a dam sill, fish ladder (or bifurcation structure), or road crossing, is counted as an individual structure. The total number of steps at structures, such as the number of steps an adult or juvenile salmon would need to jump or swim through was also evaluated.

Risk of Entrainment

Active water diversions within Reach 2B would be screened to prevent fish entrainment by screening fish from Mendota Pool, consolidating diversions, or installing individual screens on some smaller diversions. Even though the diversions would be screened, the type of screen and the size of the diversion can present some risk to out-migrating juvenile salmon or other juvenile native fishes. The risk of entrainment was evaluated by comparing the number of screens along Reach 2B that juvenile fish may encounter as they transit the reach.

Risk of Predation

Potential predation sites can develop along fish screens, at the entrance or exit of fish ladders or in association with bifurcation structures or road crossings. Potential predation sites could harbor predatory fish such as largemouth bass, smallmouth bass, Sacramento pikeminnow, striped bass, or other species. These species would be attracted to scour holes below artificial structures, or structures that create shear zones where areas of turbulent high velocity water are in close proximity to low-velocity water that would favor the feeding of opportunistic predators. The number of potential predation sites associated with structures for the Project alternatives was evaluated.

5.3.2 Significance Criteria

Significance criteria were developed based on applicable regulations and management policies, a review of the available information, and the professional judgment of the authors. The project would have a significant effect on aquatic resources if it will:

- Cause a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status fish species in local or regional plans, policies, or regulations, or by the DFW, NMFS, or USFWS.
- Interfere substantially with the movement of any native resident or migratory fish or impede the use of native fish nursery sites.
- Conflict with any local policies or ordinances protecting biological resources.
- Conflict with the provisions of an adopted or approved habitat conservation plan, or Natural Community Conservation Plan.

In addition to the thresholds of significance for impacts in the Environmental Checklist Form in Appendix G of the State CEQA Guidelines, as amended, thresholds also encompass factors taken into account under NEPA to determine the significance of an action in terms of its context and the intensity of its effects. Impacts to fish would also be considered significant if implementation, operation, or maintenance of actions included in the Project alternatives would do any of the following:

- Cause production and/or discharge of materials that pose a hazard to fish.
- Result in displacement of spawning fish such that year-class strength of any Federal or State special-status fish species or any commercially important fish species is substantially reduced.
- Substantially reduce the abundance, either directly or by reducing the amount or quality of habitat, of any life stage of a Federal or State special-status fish species or any commercially important fish species.
- Adversely modify designated critical habitat for any Federally-listed species.

5.3.3 Impacts and Mitigation Measures

There are nine impact topics selected to answer the questions above on substantial direct or indirect effects to special status, native resident, or migratory fish and their habitats:

1. Effects on Fish Habitat and Passage for Local Fish Populations
2. Effects on Salmonid Rearing Habitat
3. Effects on Upstream Migration of Adult Salmonids
4. Effects on Downstream Migration of Juvenile Salmonids
5. Effects of In-channel Construction Activities on Fish Species within Reach 2B
6. Effects of Floodplain Use by Agriculture on Fish Species within Reach 2B
7. Effects on Occurrence of Native Fish Species within Reach 2B
8. Effects on Predation of Juvenile Salmonids and Native Fish Species
9. Effects on the Aquatic Food Web within Reach 2B

Other fisheries-related issues covered in the PEIS/R are not covered here because they are programmatic in nature and/or are not relevant to the Project area.

Issues Eliminated from Further Analysis

Habitat Conservation Plans and Other Conservation Plans. Aside from the Pacific Coast Salmon Fishery Management Plan, there are no adopted habitat conservation plans, Natural Communities Conservation Plan, or other approved State, regional, or local habitat conservation plans in the Project area. Project activities would not conflict with the provisions of any such plans; therefore, this issue is not further addressed in this section.

Other Local and Regional Plans. The Fresno County General Plan and the Madera County General Plan are described under Regulatory Setting in Section 5.2.3, Regional and Local. The policies identified in these plans to protect biological resources are

consistent with requirements of other State and Federal regulations. Project activities would not conflict with these policies; therefore, local and regional plans are not further addressed in this section.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. However, other proposed actions under the SJRRP would be implemented, including habitat restoration, augmentation of river flows, and reintroduction of salmon. Without the Project in Reach 2B, however, these activities would be unlikely to achieve the Settlement goals. The potential effects of the No-Action Alternative are described below. The analysis is a comparison to existing conditions, and no mitigation is required for No-Action.

Under the No-Action Alternative, salmon would be reintroduced into the San Joaquin River as part of the Program. Downstream migrating juveniles would be entrained in diversions from Mendota Pool each spring during their outmigration. Adult salmon would be blocked on their upstream migration at Mendota Dam in all years except wet year types unless trapped and moved upstream of migration barriers in Reach 2B. Blocked adult salmon would potentially be exposed to poaching in the river below Mendota Dam and/or poor water quality later in the year. There is no spawning substrate in Reach 3, downstream of the dam, so blocked adult fish would not spawn successfully unless they were physically trapped and moved upstream of Mendota Dam.

Impact AQUA-1 (No-Action Alternative): ***Effects on Fish Habitat and Passage for Local Fish Populations.*** Under the No-Action Alternative, the Project would not be implemented and there would be no increase in flow capacity in Reach 2B, Mendota Pool bypass, no fish passage structures, no screens installed on water diversions, and no improvements to San Mateo Avenue crossing. Restoration Flows would occur below Friant Dam to the Merced River, but be limited to than-existing channel capacities. In the context of the Project area, Restoration Flows would provide benefits from the Chowchilla Bifurcation Structure to Mendota Pool by wetting the channel upstream of Mendota Pool and through more frequent and longer duration flows than those that occur under existing conditions. In addition to benefits attributed to the fish population in Reach 2B, Restoration Flows would have benefits throughout the Program area. Compared to existing conditions, the No-Action Alternative would have a **beneficial** effect on fisheries associated with increased flows in the San Joaquin River but would not fully meet the Project purpose and need or achieve the Settlement goals.

Impact AQUA-2 (No-Action Alternative): ***Effects on Salmonid Rearing Habitat.*** Under the No-Action Alternative, none of the proposed fish passage or protection facilities or floodplain habitat associated with setback levees within the Project area would be implemented. As described above, however, rearing habitat conditions would be enhanced from Restoration Flows in the Project area within the existing channel. Restoration Flows would wet an otherwise dry channel upstream of Mendota Pool and seasonal flows would substantially inundate the channel more frequently. Compared to existing conditions, the No-Action Alternative would have a **beneficial** effect on juvenile

salmonid rearing habitat associated with increased flows in the San Joaquin River but would not fully meet the Project purpose and need or achieve the Settlement goals.

Impact AQUA-3 (No-Action Alternative): *Effects on Upstream Migration of Adult Salmonids.* Under the No-Action Alternative, fish passage facilities for upstream migration would not be implemented for the Project, but Restoration Flows would occur below Friant Dam to the Merced River. As part of the Program, other impediments to upstream migrating salmon would be modified to facilitate passage (e.g., Hills Ferry Barrier, Sack Dam). Under the No-Action Alternative, adult salmon likely would be trapped and moved upstream of migration barriers in Reach 2B as a Program action. Trapping and transporting adult Chinook salmon presents physiological stress for the fish that could result in reduced physical condition, injury, or in some cases, mortality. However, transporting Chinook salmon around barriers to access suitable spawning grounds would still have a beneficial effect, since fish downstream of barriers are not likely to find suitable spawning habitat. Compared to existing conditions, the No-Action Alternative would have a **beneficial** effect on upstream passage of adult salmon through trap and transport implemented by the Program but would not fully meet the Project purpose and need or achieve the Settlement goals.

Impact AQUA-4 (No-Action Alternative): *Effects on Downstream Migration of Juvenile Salmonids.* Under the No-Action Alternative, facilities associated with the Project would not be implemented, but Restoration Flows would occur below Friant Dam to the Merced River. Under existing conditions, the section of Reach 2B between the Chowchilla Bifurcation structure and San Mateo Avenue is often dry during the outmigration season. Under the No-Action Alternative, Restoration Flows would provide contiguous habitat connectivity from Friant Dam to the Merced River during typical outmigration periods for salmon and steelhead. Under the No-Action Alternative, juvenile salmon would migrate downstream through Reach 2B and would be exposed to several large, medium, and small unscreened diversions between the Chowchilla Bifurcation Structure and Mendota Dam. Although the flows and increased habitat connectivity would be an improvement over the dry conditions that typify existing conditions, without appropriately screened pumps and diversion structures juveniles would be subjected to high mortality rates as they encounter false migration pathways (i.e., canals and diversions) and experience mortality in pumps. Compared to existing conditions, the No-Action Alternative would have a **beneficial** effect on downstream migration of salmonid species but would not fully meet the Project purpose and need or achieve the Settlement goals.

Impact AQUA-5 (No-Action Alternative): *Effects of In-channel Construction Activities on Fish Species within Reach 2B*. Under the No-Action Alternative, no construction activity would occur in the active channel and there would be no adverse effects on aquatic species associated with construction-related crushing, disturbance, release of sediment, or release of pollutants from equipment operation and ground disturbance activities. Under the No-Action Alternative, the Project would not be implemented and there would be no Project-related short-term construction activities in the Project area. As a result, there would be **no impact** on existing aquatic resources within Reach 2B.

Impact AQUA-6 (No-Action Alternative): ***Effects of Floodplain Use by Agriculture on Fish Species within Reach 2B.*** Existing levees are not set back from the river channel. No agricultural practices presently occur within the existing levees. Under the No-Action Alternative, the Project would not be implemented and there would be no levee set-back and no agricultural use of lands within the existing levees. Compared to existing conditions, there would be **no impact** to fish species.

Impact AQUA-7 (No-Action Alternative): ***Effects on Occurrence of Native Fish Species within Reach 2B.*** Under the No-Action Alternative, the Project would not be implemented and no fish passage or screening facilities would be constructed and no channel improvements would occur. Restoration Flows would occur below Friant Dam to the Merced River. In addition to benefits attributed to the fish population in Reach 2B, Restoration Flows would have benefits throughout the Program area. In the context of the Project area, Restoration Flows within the existing channel capacity would provide benefits from the Chowchilla Bifurcation Structure to Mendota Pool by wetting the channel upstream of Mendota Pool and through more frequent and longer duration flows than those that occur under existing conditions. Compared to existing conditions, the No-Action Alternative would have a **beneficial** effect on native fishes associated with increased flows in the San Joaquin River but would not fully meet the Project purpose and need or achieve the Settlement goals.

Impact AQUA-8 (No-Action Alternative): ***Effects on Predation of Juvenile Salmonids and Native Fish Species.*** Restoration Flows could alter the presence and distribution of non-native predatory fish within Reach 2B. Under the No-Action Alternative, the Project would not be implemented, and no fish passage or screening facilities would be constructed and no channel improvements would occur. Restoration Flows would occur below Friant Dam to the Merced River. In addition to benefits attributed to the fish population in Reach 2B, Restoration Flows would have benefits throughout the Program area and would provide predator fish with better habitat conditions as well. In the context of the Project area, Restoration Flows would provide more opportunities for predators to move into Reach 2B, but would also provide improved habitat for native fishes. Prior to Interim Flows, habitat in Reach 2B was only marginally suitable for native fishes and supported more nonnative fishes than natives; however, increased flow would likely improve native habitat, allow native fishes to multiply in the reach, and increase the proportion of native fishes in Reach 2B. Because the proportion of native fishes is likely to increase as compared to non-native fishes, effects from predation would be reduced, and therefore the No-Action Alternative would have a **beneficial** effect on native fishes as compared to existing conditions.

Impact AQUA-9 (No-Action Alternative): ***Effects on the Aquatic Food Web within Reach 2B.*** Under the No-Action Alternative, the Project would not be implemented, but Restoration Flows would occur below Friant Dam to the Merced River. Levees would not be set back, but channel areas that are typically dry under existing conditions would be inundated under Restoration Flows, which would potentially create conditions for primary and secondary production which would otherwise not occur. Also, as noted in Impact AQUA-4 (No-Action Alternative), Restoration Flows would provide near contiguous habitat connectivity from Friant Dam to the Merced River, which would

potentially bring nutrients and insects from upstream reaches that have different environmental conditions (e.g., gravel in Reach 1) and different insect drift components than found in Reach 2B (e.g., greater proportion of macroinvertebrates). Compared to existing conditions, the inundation of additional existing channel areas under the No-Action Alternative would have a **beneficial** effect on the aquatic food web but would not fully meet the Project purpose and need or achieve the Settlement goals.

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

Under Alternative A, construction of new Project facilities would occur, including a new levee system capable of conveying flows up to 4,500 cfs with 3 feet of freeboard; the Compact Bypass capable of conveying Restoration Flows up to 4,500 cfs around Mendota Pool and Dam; and 10 to 18 grade control structures to aid in upstream passage of adult salmon and other native fishes. A fish guidance barrier would be installed in the San Joaquin River where the Compact Bypass joins the river in Reach 3 to direct upstream adult salmon into the bypass. The Mendota Pool Dike would be constructed across the existing San Joaquin River arm of Mendota Pool to isolate the Mendota Pool from the San Joaquin River and direct flows into the Compact Bypass. The San Mateo Avenue Crossing would be improved. The crossing would accommodate the increased flows in the river by maintaining the required velocities for proper fish passage for flows up to 4,500 cfs. Alternative A includes construction of the South Canal with a bifurcation structure that would provide up to 2,500 cfs diversion into the South Canal and up to 4,500 cfs to the San Joaquin River. The South Canal intake would include a NMFS-compliant fish screen capable of screening juvenile salmon up to flows of 2,500 cfs with a fish return system that would convey screened fish back to the river. An upstream fish passage facility would be constructed at the South Canal bifurcation structure to provide upstream passage when operations prevent passage through the structure. The existing San Joaquin River control structure of the Chowchilla Bifurcation Structure would be removed.

Alternative A would include three upstream fish passage structures (the Compact Bypass grade control structures, San Mateo Avenue and South Canal bifurcation structure, and fish passage facility) that would include up to 43 steps. Downstream migrating fish would encounter the Lone Willow Slough, South Canal, South Canal passage supplemental flow, and Big and Little Bertha fish screens. Most major diversions that currently divert water from Mendota Pool would be isolated from the San Joaquin River.

This alternative would also create a floodplain with an average width of approximately 3,000 feet with low-lying areas on the floodplain connected to the river to prevent fish stranding. The alternative would restore floodplain habitat that would provide about 850 acres of seasonal rearing habitat (about 470 acres of primary production habitat and 380 acres of rearing habitat) for juvenile salmon and other native fishes at a flow of about 2,500 cfs. The alternative would allow agricultural practices in the floodplain (e.g., annual crops, pasture, or floodplain-compatible permanent crops). No changes would occur at Mendota Dam, under Alternative A, although this facility would be isolated from fish migration pathways. Construction activity is expected to occur intermittently over 102 to 132 months (8.5 to 11 years).

Impact AQUA-1 (Alternative A): *Effects on Fish Habitat and Passage for Local Fish Populations.* Compared to the No-Action Alternative, there would be major improvements to habitat quality and quantity, improvements to downstream migration by installation or isolation of the major diversions, and improvements to upstream fish passage around Mendota Dam, at the San Mateo Avenue crossing, and at the South Canal bifurcation structure under Alternative A. Additionally, Alternative A would add floodplain habitat to the river system and convey flows up to 4,500 cfs. Collectively, Alternative A would increase the amount of habitat and improve habitat quality through the added floodplain area for all fish species, reduce losses through unscreened diversion, and improve conditions for upstream passage from Reach 3 to Reach 2A. Conveying Restoration Flows and providing fish passage also restores connectivity of Reach 2B to the rest of the river, and would benefit the entire Restoration Area.

Compared to existing conditions, Alternative A would increase capacity for Restoration Flows, result in improved up and downstream passage, reduce losses to diversions, and increase floodplain habitat. Alternative A would have a **beneficial** effect on fisheries associated with increased mobility within the river, and would improve and expand habitat within Reach 2B.

Impact AQUA-2 (Alternative A): *Effects on Salmonid Rearing Habitat.* Compared to the No-Action Alternative, Alternative A would construct levees capable of conveying 4,500 cfs within Reach 2B. The new levee system would create a 3,000-foot-wide floodplain through Reach 2B that would support food production and rearing habitat. Alternative A would allow inundation of 850 acres of floodplain at 2,500 cfs. This magnitude of flow would create approximately 470 acres of shallow water habitat (less than 1 foot deep) for primary production, and approximately 380 acres of deeper habitat that could directly support rearing conditions (see Figure 2-9 of Chapter 2, “Description of Alternatives”). Floodplain areas adjacent to the main channel would start inundating between 1,200 and 2,200 cfs and would encourage riparian regeneration. Riparian trees may potentially contribute large woody debris to the river channel that could be used as cover by juvenile salmonids within the river channel and on the floodplain.

Compared to existing conditions, Alternative A would enhance overall floodplain acreage along Reach 2B and provide capacity for up to 4,500 cfs. The floodplain areas adjacent to the main channel would provide additional rearing habitat not otherwise available under existing conditions. These floodplains along the river would provide additional rearing habitat and may provide sites for riparian establishment that, in time, could improve habitat conditions for juvenile rearing in Reach 2B. Alternative A would provide a **beneficial** effect on rearing habitat for juvenile salmonid species rearing in Reach 2B.

Impact AQUA-3 (Alternative A): *Effects on Upstream Migration of Adult Salmonids*. Compared to the No-Action Alternative, Alternative A would provide upstream passage from Reach 3 through Reach 2B and into Reach 2A. A fish guidance barrier would be constructed to direct fish into the Compact Bypass. The Compact Bypass would be constructed with 10 to 18 grade control steps to facilitate upstream passage. A dike separating the San Joaquin River from the Mendota Pool would minimize adult fish straying into false migration pathways. The San Mateo Avenue crossing would be rebuilt

to provide passage for adults at all migration flows. The most upstream feature adult fish would encounter is the South Canal bifurcation structure that would have fish passage provided in the form of a ladder or rock ramp fishway. The San Joaquin River control structure of the Chowchilla Bifurcation Structure would be removed, and its function would be combined with the South Canal bifurcation structure so adults could swim unimpeded into Reach 2A. Diversions would be consolidated and screened. There would be a total of 43 hydraulic jumps fish would have to pass over three river-spanning structures between Reach 3 and Reach 2A (Compact Bypass grade control structures, San Mateo Avenue, and the South Canal bifurcation structure and passage facility). All diversions would be screened or isolated in Mendota Pool, which would eliminate false migration pathways.

Under existing conditions, upstream migrating adult salmon are restricted from entering Reach 2B by Mendota Dam, and would have difficulty passing San Mateo Avenue during low flow ranges and passing the San Joaquin River control structure of the Chowchilla Bifurcation Structure at some flows. Adult salmon could also stray into the DMC, Main Canal, Helm Ditch, and Fresno Slough or into the Columbia Canal approach channel. In comparison to existing conditions, Alternative A would establish fish passage from Reach 3 through Reach 2B and into Reach 2A. Alternative A would have a **beneficial** effect by facilitating upstream migration for adult salmon and by isolating or screening possible false migration pathways.

Impact AQUA-4 (Alternative A): *Effects on Downstream Migration of Juvenile Salmonids*. Compared to the No-Action Alternative, Alternative A would improve downstream passage by screening water diversions, isolating operations of Mendota Pool from the river, and providing improved downstream passage for juvenile salmon. The South Canal bifurcation structure would provide for downstream juvenile passage and the South Canal would be screened for diversions. Screened juvenile fish would be directed back to the San Joaquin River and would not pass through Mendota Pool where they are exposed to loss through diversions and predators. Downstream fish passage would be improved at the San Mateo Avenue crossing and through the Compact Bypass, where juvenile fish would pass downstream into Reach 3 without having to pass through Mendota Dam. Under all the alternatives, fish passage and fish screening designs would be based upon criteria from Anadromous Salmonid Passage Facility Design (NMFS 2008) and Guidelines for Salmonid Passage at Stream Crossings (NMFS 2001). Design would be further informed by the flow and depth criteria detailed in Table 2-1 of Chapter 2, “Description of Alternatives.” Outmigrating juvenile salmon would encounter four fish screens and 21 potential predation sites as they pass from Reach 2A through Reach 2B and into Reach 3.

Compared to existing conditions, Alternative A, like the No-Action Alternative, would greatly improve downstream passage for juvenile salmonids through Reach 2B from Reach 2A into Reach 3. Alternative A would have a **beneficial** effect by facilitating downstream passage.

Impact AQUA-5 (Alternative A): *Effects of In-channel Construction Activities on Fish Species within Reach 2B*. Compared to the No-Action Alternative, construction

activity in the active channel could result in adverse effects on aquatic species, including crushing, disturbance of organisms, release of sediment, and release of pollutants associated with ground disturbance or equipment operation. Adverse effects to fish during in-channel construction activities would be minimized by including some or all of the following measures (see Section 2.2.4):

- Temporary bypass facilities around construction areas that meet fish passage criteria.
- Construction in the dry (i.e., not in active flows).
- Phased construction that would allow passage to continue in the channel or in the completed portions of structures while other portions are built.
- Fish rescue and relocation.

Cofferdams would likely be used to construct the Mendota Pool Dike, San Mateo Avenue Crossing, the fish screen return outlets, and the South Canal bifurcation structure. All other structures would likely be constructed in the dry.

The Project would implement Conservation Measures EFH-1, EFH-2, CVS-1, CVS-2, PL-1, GS-1, and SRCS-1 to avoid or minimize adverse effects on Central Valley Chinook salmon, Central Valley steelhead, pacific lamprey, green sturgeon, and associated habitat (see Section 2.2.10, Table 2-8). Adverse effects from construction activities would be minimized through the following measures:

- Disturbance of riparian vegetation would be avoided to the greatest extent practicable (Conservation Measure EFH-1).
- In-channel construction activities that could affect Pacific salmonid habitat would be limited to the low-flow period between June 1 and October 1 to minimize potential for adversely affecting Federally-listed anadromous salmonids during their emigration period (Conservation Measure EFH-2).
- In-channel construction activities that could affect habitat for Pacific salmonids would be limited to daylight hours during weekdays, leaving a nighttime and weekend period of passage for Federally-listed fish species (Conservation Measure EFH-2).
- Work in documented areas of Pacific lamprey presence would be timed to avoid in-channel work during typical lamprey spawning (March 1 to July 1). If temporary dewatering in documented areas of lamprey presence is required for instream channel work, salvage methods would be implemented to capture and move ammocoetes to a safe area, in consultation with USFWS (Conservation Measure PL-1).
- Actions that would affect an introduced experimental population of Central Valley spring-run Chinook salmon would be performed in accordance with the Experimental Population 4(d) rule, where applicable (Conservation Measure SRCS-1).

The Project would also implement the following control measures to avoid or minimize release of sediment or pollutants to the river (see Section 2.2.10, Table 2-8):

- A spill prevention plan would be prepared describing measures to be taken to minimize the risk of fluids or other materials used during construction (e.g., oils, transmission and hydraulic fluids, cement, fuel) from entering the San Joaquin River or contaminating riparian areas adjacent to the river itself. Stockpiling of materials, including portable equipment, vehicles and supplies, such as chemicals, would be restricted to designated construction staging areas, exclusive of any riparian and wetland areas (Conservation Measure EFH-1).
- Construction Best Management Practices (BMPs) for off-channel staging and storage of equipment and vehicles would be implemented. BMPs would also include minimization of erosion and stormwater runoff, as appropriate (Conservation Measure EFH-2).
- A qualified biological monitor would be present during all construction activities, including clearing, grubbing, pruning, and trimming of vegetation at each job site during construction initiation, midway through construction, and at the close of construction to monitor implementation of conservation measures and water quality (Conservation Measure EFH-1).

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to No-Action). Because control measures would be implemented to minimize adverse effects from in-channel construction activities, and because these impacts would occur intermittently within the overall construction timeframe for the entire Project, they are considered **less than significant**.

Impact AQUA-6 (Alternative A): ***Effects of Floodplain Use by Agriculture on Fish Species within Reach 2B.*** Compared to the No-Action Alternative, Alternative A would allow for agricultural use on the expanded floodplains within the levees. Juvenile salmon have been shown to grow more rapidly on the inundated Yolo Bypass floodway when compared to juveniles that remain in the Sacramento River (Sommer et al. 2001). A similar relationship is postulated for the San Joaquin River in Reach 2B. Agricultural use of these lands presently occurs, and moving the levees as part of Alternative A would incorporate these agricultural lands into the floodplain. The majority of the expanded floodplain would become inundated about every 2 years at flows of around 2,500 cfs and higher. Grazing of livestock, pasture, planting annual crops, or planting floodplain-compatible permanent crops would be the agricultural activities implemented on the floodplain between the levees. It is also assumed for the purpose of this analysis that agricultural activities would not occur within 300 feet of the active channel and would also not occur on any constructed floodplain benches adjacent to the main channel or on secondary channels. While flooding of a native floodplain may improve rearing habitat for outmigrating juvenile salmonids, agricultural activities may introduce contaminants (fertilizers, pesticides, manure) directly to the floodplain where they could potentially become entrained in the flow and affect juvenile fish rearing in Reach 2B or in downstream reaches.

Under existing conditions, no agricultural activities occur inside the existing levee alignments. Agricultural crops are presently grown on the area that would be incorporated into the wider floodplain, but these crops are primarily permanent crops (e.g., almonds, pistachios, grapes) that would not be suitable crops to grow in the floodplain and subject to inundation. Compared to existing conditions, agricultural uses under Alternative A would result in periodic soil disturbance, deposition of animal waste, fertilizer or pesticide applications associated with planting of grasses, annual crops or floodplain-compatible permanent crops on the floodplain. These activities would likely occur during periods when the floodplain is dry. Applicable agricultural practices would be in compliance with regulations from the Irrigated Lands Regulatory Program (see Section 14.2.3 for a description of this program). Agricultural use of the floodplain would result in an indirect impact to rearing salmonids in Reach 2B. Because these impacts would occur intermittently throughout the agricultural uses and occur under the control of existing programs, they are considered **less than significant**.

Impact AQUA-7 (Alternative A): *Effects on Occurrence of Native Fish Species within Reach 2B.* Compared to the No-Action Alternative, modifications within Reach 2B would facilitate up and downstream passage for native fishes in addition to juvenile and adult salmon. Native fish include lamprey species, Sacramento sucker, Sacramento pikeminnow, hardhead, hitch, Sacramento blackfish, prickly sculpin, and others. While Restoration Flows would assist in native species dispersal from upstream, the fish passage facilities would aid in downstream dispersal. Fish screens designed to help protect juvenile salmon and larger life stages would also protect similar sized juvenile fish from entrainment into diversions. The increased capacity and expansion of floodplains would also produce additional habitat for rearing larval and juvenile native fishes, in addition to habitat available in the channel. Isolation of Mendota Pool from the San Joaquin River would also provide a benefit to native fishes dispersing through the river or living in Reach 2B.

Under existing conditions, native fish moving downstream in Reach 2B are exposed to entrainment at the many unscreened diversions in Mendota Pool. Except for flood years, native fishes are not able to pass upstream over Mendota Dam and may also have difficulty moving upstream of the San Mateo Avenue crossing or through the Chowchilla Bifurcation Structure. Native fishes are exposed to nonnative piscivores in Mendota Pool. Compared to existing conditions, Alternative A would screen diversions along the San Joaquin River. While screens would not be designed specifically to screen all life stages of native fish, they would be designed to screen fry-sized and larger salmon, and would reduce the loss of juvenile life stages of native fishes to the diversions. Isolating the Pool from the river would reduce predation in Mendota Pool. Increasing capacity, expanding the floodplain, and adding floodplain benches adjacent to the main channel would provide additional habitat that would support larval and juvenile native fishes. In combination, these actions would greatly improve the ability of native fishes to move through and live within Reach 2B. Compared to existing conditions, this would be a **beneficial** effect.

Impact AQUA-8 (Alternative A): *Effects on Predation of Juvenile Salmonids and Native Fish Species.* Compared to the No-Action Alternative, Alternative A would add

several structures while eliminating several features that may harbor predators along the migratory path of juvenile salmon. The No-Action Alternative has numerous diversion intakes in Mendota Dam, Mendota Pool with numerous diversion intakes, and the Chowchilla Bifurcation Structure. Alternative A would have the Compact Bypass, South Canal bifurcation structure, fish screens, and fish bypass return. The total number of potential predation sites associated with artificial structures is 21; however, the isolation of Mendota Pool from the river would eliminate a potentially large predator population from interacting with the outmigrating juvenile salmon.

Under existing conditions, juvenile salmon moving downstream in Reach 2B are exposed to predation at the flow control structures, unscreened intakes, and in Mendota Pool. Isolating the pool and many of the intake structures from the river would reduce opportunities for predation on outmigration juvenile salmon; however, additional structures would be added to the outmigration corridor, including grade control structures in the Compact Bypass and fish passage facilities at the South Canal bifurcation structure. In combination with increased capacity and the widened floodplain, these actions would greatly improve the ability of juvenile salmon to move through Reach 2B even though they would be experiencing some level of predation. Compared to existing conditions, this would be a **beneficial** effect.

Impact AQUA-9 (Alternative A): ***Effects on the Aquatic Food Web within Reach 2B.*** Compared to the No-Action Alternative, Alternative A would provide improved food-web conditions through increased capacity and expanded floodplains. Levees would be set back and floodplain areas would be expanded, making it possible to inundate the majority of the floodplain about every other year through Restoration Flows up to 4,500 cfs, which would potentially create conditions for improved primary and secondary production that would otherwise not occur.

When comparing Alternative A to existing conditions, effects on the aquatic food web would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative A to the No-Action Alternative). Compared to existing conditions, the increased floodplain area, increased frequency of inundation, and the wider floodplains under Alternative A, combined with Restoration Flows, would have a **beneficial** effect on the aquatic food web.

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Under Alternative B, construction of new Project facilities would occur, including a new levee system capable of conveying flows up to 4,500 cfs with 3 feet of freeboard; and a new bypass channel, capable of conveying Restoration Flows around Mendota Pool and Mendota Dam, with 2 to 6 grade control structures to aid in upstream passage of adult and juvenile salmon and other native fishes. A new bifurcation structure would be constructed at the head of the Compact Bypass that would control flows down the San Joaquin River and into Mendota Pool. The Mendota Pool Control Structure would include a fish screen capable of screening juvenile salmon up to flows of 2,500 cfs with a fish return system that conveys screened fish back to the Compact Bypass. The San Mateo Avenue crossing would be removed. Alternative B would modify the Chowchilla

Bifurcation Structure to improve fish passage through the San Joaquin River Control Structure and add a NMFS-approved fish passage facility on that control structure when operations prevent passage through the structure.

Alternative B would include three upstream passage structures (Compact Bypass grade control structures, Compact Bypass Bifurcation Structure and fish passage facility, and the Chowchilla Bifurcation Structure and fish passage facility) that would include up to 54 steps. Downstream migrating fish would encounter the Chowchilla Bifurcation Structure passage facility supplemental flow, Lone Willow Slough, Big and Little Bertha, Compact Bypass Control Structure passage facility supplemental flow, and Mendota Pool Control Structure fish screens. Most major diversions that currently divert water from Mendota Pool would be isolated from the San Joaquin River.

This alternative would also create a floodplain with an average width of approximately 4,200 feet with low-lying areas on the floodplain connected to the river to prevent fish stranding. The alternative would restore floodplain habitat that would provide about 1,000 acres of seasonal rearing habitat (about 440 acres of primary production habitat and 560 acres of rearing habitat) for juvenile salmon and other native fishes at a flow of about 2,500 cfs. The floodplain under Alternative B would be about 44 percent primary production habitat at 2,500 cfs and about 42 percent at 4,500 cfs. The alternative would allow agricultural practices in the floodplain (e.g., annual crops, pasture, or floodplain-compatible permanent crops). No changes would occur at Mendota Dam under Alternative B. Construction activity is expected to occur intermittently over 106 to 157 months (9 to 13 years).

Impact AQUA-1 (Alternative B): ***Effects on Fish Habitat and Passage for Local Fish Populations***. Compared to the No-Action Alternative, there would be major improvements to habitat quality and quantity, improvements to up and downstream fish passage, and a reduction in entrainment under Alternative B. Alternative B would increase capacity to convey up to 4,500 cfs in flows through the reach, increase the amount of habitat, and improve habitat quality for all fish species in Reach 2B. Providing fish passage also restores connectivity of Reach 2B to the rest of the river and would have benefits throughout the Program area.

Compared to existing conditions, Alternative B would result in improved up and downstream passage, reduced loss of fish to diversions, and an increase in floodplain habitat. Alternative B would have a **beneficial** effect on fisheries associated with increased survival of juvenile life stages, increase connectivity within the river, and improved and expanded habitat within Reach 2B.

Impact AQUA-2 (Alternative B): ***Effects on Salmonid Rearing Habitat.*** Compared to the No-Action Alternative, Alternative B would provide a new levee system that would create a 4,200 foot average-width floodplain through Reach 2B that would support food production and rearing habitat. The levee setbacks under Alternative B would allow inundation of 1,000 acres of floodplain at 2,500 cfs. This magnitude of flow would create approximately 440 acres of shallow water habitat (less than 1 foot deep) for primary production and approximately 560 acres of deeper habitat that could directly support

rearing conditions (see Figure 2-12 of Chapter 2, "Description of Alternatives"). Floodplain areas adjacent to the main channel would start inundating between 1,200 and 2,200 cfs and would encourage riparian regeneration. Riparian trees may potentially contribute large woody debris to the river channel that could be used as hydraulic cover by juvenile salmonids within the river channel and on the floodplain.

Compared to existing conditions, Alternative B would provide enhanced rearing conditions on the widened floodplain acreage along Reach 2B and provide capacity for up to 4,500 cfs. The floodplain areas adjacent to the main channel would provide additional rearing habitat not otherwise available under existing conditions. These floodplains along the river may provide sites for riparian establishment that, in time, could improve habitat conditions in the channel for juvenile rearing in Reach 2B. Alternative B would provide a **beneficial** effect on rearing habitat for juvenile salmonids rearing in Reach 2B.

Impact AQUA-3 (Alternative B): *Effects on Upstream Migration of Adult Salmonids*. Compared to the No-Action Alternative, Alternative B would provide upstream passage from Reach 3 through Reach 2B and into Reach 2A. The Compact Bypass would be constructed with two to six grade control steps to facilitate upstream passage. A fish passage facility (a ladder or rock ramp fish way) would provide up and downstream fish passage between the Compact Bypass and the river upstream of the Compact Bypass Control Structure during times when operation of the control structure impedes passage. The Mendota Pool Control Structure may allow some straying, but a fish screen would prevent adult fish from entering Mendota Pool. The San Mateo Avenue crossing would be removed. The Chowchilla Bifurcation Structure would have a fish passage facility to provide passage when operation impedes passage through the structure. All other diversions would be consolidated and/or screened. There would be a total of 54 hydraulic steps that fish would have to pass over three river-spanning structures between Reach 3 and Reach 2A (Compact Bypass grade control structures, Compact Bypass Control Structure and passage facility, and the Chowchilla Bifurcation Structure and passage facility). Diversions would be screened or isolated in Mendota Pool, which would eliminate false migration pathways.

This alternative does not include a fish barrier at the downstream end of the Compact Bypass to keep fish from migrating upstream of the Compact Bypass in Reach 3 toward the base of Mendota Dam. A false migration pathway up to the base of Mendota Dam – of approximately 2,000 feet – would be available to fish in all years, and a false migration pathway into Mendota Pool and Fresno Slough (potentially into the King River system) would occur about once in 5 years when the boards are taken out of Mendota Dam to pass Pine Flat flood releases into Reach 3. A false migration pathway to Mendota Dam would also occur under the No-Action Alternative. Because the Compact Bypass would provide upstream passage under Alternative B, the false migration pathway would affect less fish than under the No-Action Alternative.

When comparing Alternative B to existing conditions, effects would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative B to the No-Action Alternative). Compared to existing conditions, Alternative B would establish fish

passage from Reach 3 through Reach 2B and into Reach 2A. As described above fish passage would be greatly improved over existing conditions. Alternative B would have a **beneficial** effect by facilitating upstream migration for adult salmon and by isolating or screening possible false migration pathways.

Impact AQUA-4 (Alternative B): *Effects on Downstream Migration of Juvenile Salmonids.* Compared to the No-Action Alternative, Alternative B would improve downstream passage by screening water diversions, isolating operations of Mendota Pool from the river, and providing improved downstream passage for juvenile salmon. The Mendota Pool Control Structure may be screened for diversions. Screened juvenile fish would be directed back to the San Joaquin River in the Compact Bypass and would not pass through Mendota Pool where they would be exposed to loss through diversions and predators. Even if not screened, the Mendota Pool Fish Screen would only be operated for Exchange Contractor diversions in summer months in highly infrequent dry years or during flood flow deliveries, when flows split several times before entering Mendota Pool and fish survival through the bypasses is high. Downstream fish passage would be improved at the Chowchilla Bifurcation Structure by installation of a fish passage facility on the San Joaquin River Control Structure. A fish passage facility at the Compact Bypass Control Structure would allow fish to migrate around when operations impede downstream passage. The San Mateo Avenue crossing would be removed. Outmigrating juvenile salmon would encounter three river spanning structures, five fish screens, and nine potential predation sites as they pass from Reach 2A through Reach 2B and into Reach 3.

When comparing Alternative B to existing conditions, effects would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative B to the No-Action Alternative). Compared to existing conditions, Alternative B would greatly improve downstream passage for juvenile salmonids through Reach 2B from Reach 2A into Reach 3. Alternative B would have a **beneficial** effect by facilitating downstream passage.

Impact AQUA-5 (Alternative B): *Effects of In-channel Construction Activities on Fish Species within Reach 2B.* Compared to the No-Action Alternative, Alternative B would include in-water construction and effects would be similar to Alternative A; refer to Impact AQUA-5 (Alternative A) for details. Measures employed in Alternative A, such as in-water construction techniques, would be employed in Alternative B, and would minimize effects of the cofferdams on fish and aquatic biota in Reach 2B during construction.

Compared to existing conditions, Alternative B would have a **less than significant** impact on fish and aquatic organisms due to these measures.

Impact AQUA-6 (Alternative B): *Effects of Floodplain Use by Agriculture on Fish Species within Reach 2B.* Compared to the No-Action Alternative, Alternative B would allow for agricultural use on the expanded floodplains within the levees and effects would be similar to Alternative A; refer to Impact AQUA-6 (Alternative A), with the following exceptions. Agricultural practices (e.g., annual crops, pasture, or floodplain-

compatible permanent crops) could occur on the floodplain in previous agricultural areas outside of State-owned and public trust lands. Growers would be required to leave cover on the ground and would be required to develop and implement a Water Quality Plan, approved by the Reclamation, to meet then-existing water quality standards for coldwater fisheries beneficial in downstream areas.

Similar to Alternative A, it is also assumed for the purpose of this analysis that agricultural activities would not occur within 300 feet of the active channel and would also not occur on any constructed floodplain benches adjacent to the main channel or on secondary channels. While flooding of a native floodplain may improve rearing habitat for outmigrating juvenile salmonids, agricultural activities may introduce contaminants (fertilizers, pesticides, manure) directly to the floodplain where they could potentially become entrained in the flow and affect juvenile fish rearing in Reach 2B or in downstream reaches.

Compared to existing conditions, agricultural uses under Alternative B would result in periodic soil disturbance, deposition of animal waste, fertilizer or pesticide applications associated with planting of grasses, annual crops or floodplain-compatible permanent crops on the floodplain. These activities would likely occur during periods when the floodplain is dry. Agricultural use of the floodplain would result in an indirect impact to rearing salmonids in Reach 2B. Because these impacts would occur intermittently throughout the agricultural uses and occur under the control of a water quality plan, they are considered **less than significant**.

Impact AQUA-7 (Alternative B): ***Effects on Occurrence of Native Fish Species within Reach 2B.*** Compared to the No-Action Alternative, Alternative B would be similar in performance to Alternative A with the following exceptions; refer to Impact AQUA-7 (Alternative A) for more detail.

- Under Alternative B, there would be a greater amount of floodplain habitat restored that would produce additional habitat for rearing larval and juvenile native fishes than in Alternative A.
- Under Alternative B, upstream native fish passage would be more difficult because there is potentially 11 additional hydraulic jumps to pass than in Alternative A.
- Survival in Reach 2B may be less difficult than in Alternative A because there are 12 fewer predation sites.

Similar to Alternative A, partial or complete isolation of Mendota Pool from the San Joaquin River would also provide a benefit to native fishes dispersing through the river or living in Reach 2B. Overall, Alternative B would provide improved conditions for native fish species in Reach 2B.

Compared to existing conditions, Alternative B would have a similar or better performance than Alternative A, with the exceptions noted above. In combination, these

actions would improve the ability of native fishes to move through and live within Reach 2B. Compared to existing conditions, this would be a **beneficial** effect.

Impact AQUA-8 (Alternative B): ***Effects on Predation of Juvenile Salmonids and Native Fish Species.*** Compared to the No-Action Alternative, Alternative B would perform similarly to Alternative A with respect to predation effects; refer to Impact AQUA-8 (Alternative A) for details. Alternative B has nine potential predation sites. The No-Action Alternative includes Mendota Pool with numerous diversion intakes and predation sites and Mendota Dam. Alternative B would have improved fish passage conditions and partially or completely isolate Mendota Pool from the San Joaquin River. Overall, predation is likely reduced compared to the No-Action Alternative.

Compared to existing conditions, Alternative B would be similar in performance to Alternative A (see above). Compared to the existing conditions, overall predation would be reduced, which would be a **beneficial** effect.

Impact AQUA-9 (Alternative B): ***Effects on the Aquatic Food Web within Reach 2B.*** Compared to the No-Action Alternative, Alternative B would provide improved food-web conditions through increased capacity and expanded floodplains. Levees would be set back and floodplain areas would be expanded, making it possible to inundate the majority of the floodplain about every other year through Restoration Flows up to 4,500 cfs, which would potentially create conditions for improved primary and secondary production that would otherwise not occur.

When comparing Alternative B to existing conditions, effects on the aquatic food web would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative B to the No-Action Alternative). Compared to existing conditions, the increased floodplain area, increased frequency of inundation, and the wider floodplains under Alternative B combined with Restoration Flows would have a **beneficial** effect on the aquatic food web.

Alternative C (Fresno Slough Bypass with Narrow Floodplain and Short Canal)

Under Alternative C, construction of new Project facilities would occur, including a new levee system capable of conveying flows up to 4,500 cfs with 3 feet of freeboard. Mendota Pool would be restricted to Fresno Slough and the San Joaquin River would bypass Mendota Pool through its historic channel and would be capable of conveying Restoration Flows through Mendota Dam into Reach 3. Mendota Dam would be modified with a fish passage facility to allow passage when operations would impede passage at Mendota Dam. Five to 10 grade control structures would be added downstream of Mendota Dam to backwater the apron of Mendota Dam and facilitate fish passage. Fresno Slough Dam would be constructed in Fresno Slough with a fish directional barrier installed below the Fresno Slough Dam to prevent adult fish from migrating into Fresno Slough during Kings River flood releases. Diversions would be made to Mendota Pool by re-installing flashboards in Mendota Dam and taking water into the pool through the Short Canal. The Short Canal would be screened for juvenile salmon. Screened fish would be returned to the San Joaquin River. A fish guidance barrier would be installed below the proposed Fresno Slough Dam to guide adult salmon

upstream to the San Joaquin River. The San Mateo Avenue Crossing would be improved. Alternative C would modify the Chowchilla Bifurcation Structure to improve fish passage through the San Joaquin River Control Structure and add a fish passage facility on the structure for times when operations impede passage through the structure. Sediment removal in the San Joaquin River is assumed to occur to bring the channel bed into a new equilibrium grade through the former San Joaquin arm of the Mendota Pool.

Alternative C would include four upstream passage structures (Mendota Dam grade control structures, Mendota Dam, San Mateo Avenue and the Chowchilla Bifurcation Structure and fish passage facility) that would include up to 59 steps. Downstream migrating fish would encounter the Chowchilla Bifurcation Structure passage facility supplemental flow, Lone Willow Slough, Big and Little Bertha, and Short Canal fish screens. Most major diversions that currently divert water from Mendota Pool would be isolated from the San Joaquin River. Sediment removal in the San Joaquin River is assumed under this alternative to bring the channel bed into a new equilibrium grade through the former Mendota Pool area.

This alternative would create a floodplain with an average width of approximately 3,000 feet with low-lying areas on the floodplain connected to the river to prevent fish stranding. The alternative would restore floodplain habitat that would provide about 750 acres of seasonal rearing habitat (about 520 acres of primary production habitat and 230 acres of rearing habitat) for juvenile salmon and other native fishes at a flow of about 2,500 cfs. In this alternative, the floodplain would not be used for agricultural activities. Construction activity is expected to occur intermittently over 91 to 133 months (7.5 to 11 years).

Impact AQUA-1 (Alternative C): ***Effects on Fish Habitat and Passage for Local Fish Populations.*** Compared to the No-Action Alternative, Alternative C would be very similar to Alternative A; refer to Impact AQUA-1 (Alternative A) for details. Alternative C would increase capacity to convey up to 4,500 cfs in flows through the reach and increase the amount of habitat and improve habitat quality for all fish species in Reach 2B. Conveying Restoration Flows and providing fish passage also restores connectivity of Reach 2B to the rest of the river and would have benefits throughout the Program area.

Compared to existing conditions, Alternative C would perform similar to Alternative A. Alternative C would have a **beneficial** effect on fisheries associated with increased mobility within the river and improved and expanded habitat within Reach 2B.

Impact AQUA-2 (Alternative C): ***Effects on Salmonid Rearing Habitat.*** Compared to the No-Action Alternative, Alternative C would perform similar to Alternative A because it has about the same amount of expanded floodplain; refer to Impact AQUA-2 (Alternative A) for details. Alternative C would provide for an average floodplain of about 3,000 feet. Alternative C would allow inundation of 750 acres of floodplain at 2,500 cfs. This magnitude of flow would create approximately 520 acres of shallow water habitat (less than 1 foot deep) for primary production and approximately 230 acres of deeper habitat that could directly support rearing conditions (see Figure 2-15 of Chapter

2, "Description of Alternatives"). Alternative C would improve rearing habitat conditions for juvenile salmonids in Reach 2B.

Compared to existing conditions, Alternative C would perform similar to Alternative A, because about the same amount of expanded floodplain would occur under both alternatives. Alternative C would have a **beneficial** effect on juvenile salmon rearing habitat within Reach 2B.

Impact AQUA-3 (Alternative C): ***Effects on Upstream Migration of Adult Salmonids***. Compared to the No-Action Alternative, Alternative C would substantially improve upstream passage from Reach 3 into Reach 2A. Alternative C would typically provide passage over Mendota Dam by removing the flashboards and adding five to ten grade control structures to backwater the river over a notched Mendota Dam sill. Mendota Pool would be restricted to Fresno Slough with water delivery from the San Joaquin River into Mendota Pool through the Short Canal. When water deliveries from the San Joaquin River are made to Mendota Pool, the flashboards would be installed in the dam and passage would occur through a fish passage facility around the dam. A fish directional barrier would be installed below the Fresno Slough Dam to prevent adult fish from migrating into Fresno Slough during Kings River flood releases from the Fresno Slough Dam. The San Mateo Avenue crossing would be improved. The Chowchilla Bifurcation Structure would have a fish passage facility to provide passage when operation impedes passage through the structure. All other diversions would be consolidated and screened. Upstream migration adults would encounter four river spanning structures (Mendota Dam grade control structures, Mendota Dam, San Mateo Avenue, and Chowchilla Bifurcation Structure and passage facility) with up to 59 steps. Alternative C would improve passage conditions compared to the No-Action Alternative.

Under existing conditions, upstream migrating adult salmon are restricted from entering Reach 2B by Mendota Dam. In comparison to existing conditions, Alternative C would create fish passage through Reach 2B from Reach 3 and into Reach 2A (see above). Alternative C would have a **beneficial** effect by allowing upstream migrating adults to pass upstream to potential spawning habitat.

Impact AQUA-4 (Alternative C): ***Effects on Downstream Migration of Juvenile Salmonids***. In comparison to the No-Action Alternative, Alternative C would improve downstream passage of juvenile salmonids by screening water diversions, isolating operations of Mendota Pool from the river and providing improved downstream passage for juvenile salmon. Juvenile salmon would be prevented from entering Mendota Pool by a fish screen at the head of the Short Canal. Downstream fish passage would be improved at the Chowchilla Bifurcation Structure by installation of a fish passage facility on the San Joaquin River Control Structure. The San Mateo Avenue crossing would be improved to facilitate downstream passage. Outmigrating juvenile salmon would encounter four river spanning structures, five fish screens, and 14 potential predation sites as they move through Reach 2B.

Compared to existing conditions, Alternative C would improve downstream migration of juvenile salmonids through Reach 2B from Reach 2A into Reach 3 for the same reasons

as mentioned in the above paragraph. As such, Alternative C would have a **beneficial** effect on downstream passage of juvenile salmonids.

Impact AQUA-5 (Alternative C): *Effects of In-channel Construction Activities on Fish Species within Reach 2B*. Compared to the No-Action Alternative, Alternative C would include in-water construction, and the effects would be similar to Alternative A; refer to Impact AQUA-5 (Alternative A) for details. Measures employed in Alternative C, such as in-water construction techniques, would be the same as those employed in Alternative A, and would minimize the effects of the cofferdams on fish and aquatic biota in Reach 2B during construction.

Compared to existing conditions, Alternative C would have a **less than significant** impact on fish and aquatic organisms due to these measures.

Impact AQUA-6 (Alternative C): *Effects of Floodplain Use by Agriculture on Fish Species within Reach 2B*. Similar to the No-Action Alternative, Alternative C does not support agricultural purposes on the expanded floodplains within the levees; therefore, there would be no effect of floodplain agricultural activities on rearing salmonids in Reach 2B.

Compared to existing conditions, Alternative C would have **no effect** from floodplain agricultural activities on rearing salmonids.

Impact AQUA-7 (Alternative C): *Effects on Occurrence of Native Fish Species within Reach 2B.* Compared to the No-Action Alternative, Alternative C would perform slightly better than Alternative A; refer to Impact AQUA-7 (Alternative A) for details. While both alternatives have about the same amount of floodplain for rearing larval and juvenile native fishes, Alternative C has fewer potential predation sites. Isolation of Mendota Pool from the San Joaquin River would also provide a benefit to native fishes dispersing through the river or living in Reach 2B under Alternative C. Overall, Alternative C would provide improved conditions for native fish species in Reach 2B.

Compared to existing conditions, Alternative C would have similar or better performance than Alternative A because of the reduced number of potential predation sites. In combination, the actions described above would improve the ability of native fishes to move through and live within Reach 2B. Compared to existing conditions, this would be a **beneficial** effect.

Impact AQUA-8 (Alternative C): *Effects on Predation of Juvenile Salmonids and Native Fish Species.* Compared to the No-Action Alternative, Alternative C would perform slightly better than Alternative A; refer to Impact AQUA-8 (Alternative A) for details. The No-Action Alternative includes Mendota Pool with numerous diversion intakes and associated potential predation sites while Alternative C would reduce the total number of potential predation sites to 14, isolate Mendota Pool from the San Joaquin River and minimize the number of potential predation sites remaining in the river. As a result, Alternative C would likely reduce predation compared to the No-Action Alternative.

Compared to existing conditions, Alternative C would perform slightly better than Alternative A, for the reason mentioned in the paragraph above, and would have fewer potential predation sites than Alternative A. Compared to the existing conditions, overall predation would be reduced, which would have a **beneficial** effect.

Impact AQUA-9 (Alternative C): ***Effects on the Aquatic Food Web within Reach 2B.*** Compared to the No-Action Alternative, Alternative C would perform similarly to Alternative A because both alternatives have about the same size floodplain and other such features; refer to Impact AQUA-9 (Alternative A) for details. Levees would be set back a similar distance and floodplain areas would be expanded, making it possible to inundate the majority of the floodplain about every other year through Restoration Flows up to 4,500 cfs, which would potentially create conditions for primary and secondary production that would not otherwise occur. Alternative C would improve aquatic food web conditions within Reach 2B relative to the No-Action Alternative.

When comparing Alternative C to existing conditions, effects on the aquatic food web would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative C to the No-Action Alternative). The increased floodplain area, increased frequency of inundation, and the wider floodplains under Alternative C, combined with Restoration Flows, would have a **beneficial** effect on the aquatic food web.

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Under Alternative D, construction of new Project facilities would occur, including a new levee system capable of conveying flows up to 4,500 cfs with 3 feet of freeboard. Mendota Pool would be restricted to Fresno Slough and the San Joaquin River would bypass Mendota Pool through its historic channel. The San Joaquin River would be capable of conveying Restoration Flows through Mendota Dam into Reach 3. Mendota Dam would be modified with a fish passage facility to allow passage when operations would impede passage at Mendota Dam. Five to 10 grade control structures would be added downstream of Mendota Dam to backwater the apron of Mendota Dam and facilitate fish passage. Fresno Slough Dam would be constructed in Fresno Slough with a fish directional barrier installed below the Fresno Slough Dam to prevent adult fish from migrating into Fresno Slough during Kings River flood releases. Diversions to Mendota Pool would occur at the new North Canal bifurcation structure that would provide up to 2,500 cfs diversion into the North Canal and up to 4,500 cfs to the San Joaquin River. The North Canal intake would include a fish screen capable of screening juvenile salmon and a fish return system that conveys screened fish back to the river. An upstream fish passage facility would be constructed at the North Canal bifurcation structure to provide upstream passage when operations impede passage through the structure. San Mateo Avenue crossing and the existing San Joaquin River control structure of the Chowchilla Bifurcation Structure would be removed.

Alternative D would include four upstream passage structures (Mendota Dam grade control structures, Mendota Dam, and the North Canal bifurcation structure and passage facility) totaling up to 36 steps. Downstream migrating fish would encounter the Lone Willow Slough, North Canal passage facility supplemental flow, and the North Canal and Big and Little Bertha fish screens. Most major diversions that currently divert water from

the Mendota Pool would be isolated from the San Joaquin River. Sediment removal in the San Joaquin River is assumed under this alternative to bring the channel bed into a new equilibrium grade through the former Mendota Pool area.

This alternative would create a floodplain with an average width of approximately 4,200 feet with low-lying areas on the floodplain connected to the river to prevent fish stranding. The alternative would restore floodplain habitat that would provide about 1,050 acres of seasonal rearing habitat (about 740 acres of primary production habitat and 310 acres of rearing habitat) for juvenile salmon and other native fishes at a flow of about 2,500 cfs. The alternative would allow agricultural practices in the floodplain (e.g., annual crops, pasture, or floodplain-compatible permanent crops). Construction activity is expected to occur intermittently over 97 to 158 months (8 to 13 years).

Impact AQUA-1 (Alternative D): ***Effects on Fish Habitat and Passage for Local Fish Populations.*** Compared to the No-Action Alternative, Alternative D would be very similar in performance to Alternative B; refer to Impact AQUA-1 (Alternative B) for details. Alternative D has a similar sized floodplain as Alternative B and would increase capacity to convey up to 4,500 cfs in flows through the reach, which would increase the amount of habitat and improve habitat quality for all fish species in Reach 2B. Conveying Restoration Flows and providing fish passage would also restore connectivity through Reach 2B to the rest of the river, and would have benefits throughout the Program area.

Compared to existing conditions, Alternative D would be very similar performance to Alternative B. Alternative D would have a **beneficial** effect on fisheries using and moving through Reach 2B.

Impact AQUA-2 (Alternative D): ***Effects on Salmonid Rearing Habitat***. Compared to the No-Action Alternative, Alternative D would perform similar to Alternative B; refer to Impact AQUA-2 (Alternative B) for details. Alternative D would create about the same amount of new floodplain rearing habitat that would inundate 1,050 acres at 2,500 cfs. This magnitude of flow would create approximately 740 acres of shallow water habitat (less than 1 foot deep) for primary production and approximately 310 acres of deeper habitat that could directly support rearing conditions (see Figure 2-19 of Chapter 2, “Description of Alternatives”). Floodplain benches adjacent to the main channel could encourage riparian regeneration similar to Alternative B. Alternative D would improve salmonid rearing habitat in Reach 2B.

Compared to existing conditions, Alternative D would create a substantial amount of floodplain habitat that could be used as rearing habitat for juvenile salmonids (see above), and would be similar in performance to Alternative B. Alternative D would provide a **beneficial** effect on rearing habitat for listed salmonid species by expanding floodplain habitat supporting rearing juvenile salmon.

Impact AQUA-3 (Alternative D): ***Effects on Upstream Migration of Adult Salmonids***. In comparison to the No-Action Alternative, Alternative D would improve upstream passage from Reach 3 into Reach 2B, and from Reach 2B into Reach 2A. Under this alternative, the concrete portions of Mendota Dam would remain in place, the sill would

be notched to improve fish passage and the five to 10 grade control structures installed downstream to backwater the river over the sill. The flash boards at the dam would be removed and flows would pass over the notched sill. The Fresno Slough Dam would be constructed in Fresno Slough with a fish directional barrier installed below the Fresno Slough Dam to prevent adult fish from migrating into Fresno Slough during Kings River flood releases. The North Canal bifurcation structure would be constructed to allow water deliveries from Reach 2B to Mendota Pool and to control flows from the San Joaquin River into the Chowchilla Bypass. The San Mateo Avenue road crossing and the existing San Joaquin River control structure of Chowchilla Bifurcation Structure would be removed under this alternative. Alternative D would result in three main river spanning structures (Mendota Dam grade control structures, Mendota Dam, and the North Canal bifurcation structure and passage facility) having up to 36 steps. All diversions would be screened or isolated in Mendota Pool, which would eliminate false migration pathways.

Under existing conditions, upstream migrating adult salmonids are restricted from entering Reach 2B by Mendota Dam, and would have difficulty passing San Mateo Avenue during low flow ranges and passing the San Joaquin River control structure of the Chowchilla Bifurcation Structure at some flows. Adult salmon could also stray into the DMC, Main Canal, Helm Ditch, and Fresno Slough or into the Columbia Canal approach channel. In comparison to existing condition, Alternative D would improve upstream fish passage through Reach 2B from Reach 3 and into Reach 2A for the reasons mentioned above. Alternative D would have a **beneficial** effect by allowing upstream migrating adults to pass upstream to potential spawning habitat.

Impact AQUA-4 (Alternative D): ***Effects on Downstream Migration of Juvenile Salmonids***. In comparison to the No-Action Alternative, Alternative D would be similar in performance to Alternative C; refer to Impact AQUA-4 (Alternative C) for details. Juvenile fish would encounter the same number of fish screens and potential predation sites as they would under Alternative C, so performance of the two alternatives for downstream migration would be similar. Alternative D would improve conditions relative to the No-Action Alternative.

Compared to existing conditions, Alternative D would be similar in performance as Alternative C, because fish would encounter the same number and types of fish screens and potential predation sites. As such, Alternative D would have a **beneficial** effect on downstream passage of juvenile salmonids.

Impact AQUA-5 (Alternative D): ***Effects of In-channel Construction Activities on Fish Species within Reach 2B.*** Compared to the No-Action Alternative, Alternative D would include in-water construction and effects would be similar to Alternative A; refer to Impact AQUA-5 (Alternative A) for details. Measures employed in Alternative A, such as in-water construction techniques, would be employed in Alternative D, and would minimize effects of the cofferdams on fish and aquatic biota in Reach 2B during construction.

Compared to existing conditions, Alternative D would have a **less than significant** impact on fish and aquatic organisms due to these measures.

Impact AQUA-6 (Alternative D): *Effects of Floodplain Use by Agriculture on Fish Species within Reach 2B.* Compared to the No-Action Alternative, Alternative D would perform similarly to Alternative A; refer to Impact AQUA-6 (Alternative A) for details. Agricultural use of these lands presently occurs under the No-Action Alternative, moving the levees would incorporate these agricultural lands into the floodplain. The majority of the expanded floodplain would become inundated about every 2 years at flows of around 2,500 cfs and higher. Juvenile salmon have been shown to grow more rapidly on the inundated Yolo Bypass floodway when compared to juveniles that remain in the Sacramento River (Sommer et al. 2001). A similar relationship is postulated for the San Joaquin River in Reach 2B.

Grazing of livestock, pasture, planting annual crops, or planting floodplain-compatible permanent crops would be the agricultural activities implemented on the floodplain between the levees. It is also assumed for the purpose of this analysis that agricultural activities would not occur within 300 feet of the active channel and would also not occur on any constructed floodplain benches adjacent to the main channel or on secondary channels. While flooding of a native floodplain may improve rearing habitat for outmigrating juvenile salmonids, agricultural activities may introduce contaminants (fertilizers, pesticides, manure) directly to the floodplain where they could potentially become entrained in the flow and affect juvenile fish rearing in Reach 2B or in downstream reaches.

Under existing conditions, no agricultural activities occur inside the existing levees. Agricultural crops are presently grown on the area that would be incorporated into the wider floodplain, but these crops are primarily permanent crops (e.g., almonds, pistachios, grapes) and would likely not be suitable crops to grow in the floodplain. Compared to existing conditions, agricultural uses under Alternative D would result in periodic soil disturbance, deposition of animal waste, fertilizer or pesticide applications associated with planting of grasses, annual crops or floodplain-compatible permanent crops on the floodplain. These activities would likely occur during periods when the floodplain is dry. Agricultural use of the floodplain would result in an indirect impact to rearing salmonids in Reach 2B. Because these impacts would occur intermittently throughout the agricultural uses and occur under the control of existing programs, they are considered **less than significant**.

Impact AQUA-7 (Alternative D): *Effects on Occurrence of Native Fish Species within Reach 2B.* Compared to the No-Action Alternative, modifications within Reach 2B under Alternative D would be similar in performance to Alternative B; refer to Impact AQUA-7 (Alternative B) for details. The increased capacity and expansion of floodplains would produce additional habitat for rearing larval and juvenile native fishes. Similar to other alternatives, isolation of Mendota Pool from the San Joaquin River would also provide a benefit to native fishes dispersing through the river or living in Reach 2B.

Compared to existing conditions, Alternative D would have similar performance as Alternative B (see above). Alternative D would have one less fish screen (four instead of five) fewer predation sites (14 instead of 22), which would improve the performance of Alternative D relative to Alternative B. In combination, these actions would improve the

ability of native fishes to move through Reach 2B and greatly expand the habitat within Reach 2B. Compared to existing conditions, this would be a **beneficial** effect.

Impact AQUA-8 (Alternative D): *Effects on Predation of Juvenile Salmonids and Native Fish Species.* Compared to the No-Action Alternative, Alternative D would perform similar to Alternative C; refer to Impact AQUA-8 (Alternative C) for details.

The No-Action Alternative includes continued operation of Mendota Pool with numerous diversion intakes and associated potential predation sites, and potential predation sites at Mendota Dam and the Chowchilla Bifurcation Structure. Alternative D would have potential predation sites at the North Canal bifurcation structure, Mendota Dam, and the Mendota Dam grade control structures. However, the North Canal fish screen would screen water flowing into Mendota Pool and the pool would be isolated from the river. The San Joaquin River control structure of the Chowchilla Bifurcation Structure and the San Mateo Avenue crossing would be removed. Alternative D would reduce predation compared to the No-Action Alternative.

Compared to existing conditions, Alternative D would be similar in performance to Alternative C (see above). Alternative D has the same number of screens and potential predation sites as Alternative C. Compared to the existing conditions, this would be a **beneficial** effect.

Impact AQUA-9 (Alternative D): *Effects on the Aquatic Food Web within Reach 2B.* Compared to the No-Action Alternative, Alternative D would be similar in performance to Alternative B, because both alternatives have about the same amount of floodplain habitat; refer to Impact AQUA-9 (Alternative B) for details. Levees would be set back and floodplain areas would be expanded, making it possible to inundate the majority of the floodplain about every other year through Restoration Flows up to 4,500 cfs, which would potentially create conditions for improved primary and secondary production that would otherwise not occur.

When comparing Alternative D to existing conditions, effects on the aquatic food web would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative D to the No-Action Alternative). Compared to existing conditions, the increased floodplain area, increased frequency of inundation, and the wide floodplains under Alternative D, combined with Restoration Flows, would have a **beneficial** effect on the aquatic food web.

6.0 Biological Resources – Vegetation

This chapter describes the environmental and regulatory setting for vegetation and special-status plants in the Project area, analyzes the environmental consequences associated with the Project alternatives, and identifies impacts and mitigation measures.

6.1 Environmental Setting

Biological resources addressed in this section include special-status plants, vegetation alliances, and non-native invasive plant species. Existing conditions are the baseline biological resource conditions that existed when the Notice of Intent and Notice of Preparation were filed, which was July 2009. However, field data were collected at later dates, after the start of Interim Flows. Therefore, the best available information to describe existing conditions was typically from the period after the start of Interim Flows.

6.1.1 Regional Setting

The San Joaquin River downstream of Friant Dam is a deeply incised channel that discharges to the San Joaquin Valley floor near Gravelly Ford. The San Joaquin River and its main tributaries in their historic natural state meandered across alluvial fans along the main axis of the valley. The river distributed higher flows into a complex network of sloughs that branched off both sides of the river. It flowed through a flat, homogeneous topography and supported a limited riparian forest. The flat valley floor surrounding the riparian forest supported extensive wetlands dominated by tule marsh. Riparian forest zones were present along the margins of the main channel and were not very extensive (The Bay Institute 1998).

Near Mendota, the San Joaquin River merged with Fresno Slough, which was part of an intricate slough system that exchanged water between the Tulare Lake Basin and the San Joaquin River. Downstream from Mendota, the San Joaquin River flowed through a network of large slough channels supporting riparian woodlands, tule marshes, and backwater ponds until the Merced River confluence. Downstream from this point, the floodplain was more confined and the river exhibited a highly sinuous pattern of meanders with a complex of oxbow lakes, backwater sloughs, ponds, and sand bars. In its lower sections just upstream from the Delta, the river formed low natural levees approximately 6 feet high (The Bay Institute 1998).

The San Joaquin River has changed dramatically since the early 20th century. The river is now largely confined within constructed levees and bounded by agricultural and urban development, flows are regulated through dams and water diversions, and floodplain habitats have been fragmented and reduced in size and diversity (McBain and Trush 2002). As a result, the riparian communities and associated wildlife have substantially changed from historic conditions (Bureau of Reclamation [Reclamation] 1998a).

Vegetation in the Restoration Area has been heavily impacted by levee construction, conversion of riparian areas into agricultural fields, ongoing agricultural practices, livestock grazing, introduction of non-native invasive plant species, and the quantity and duration of river flows. In typical water years, Friant Dam is operated to store flows in the spring for water deliveries during the summer months, resulting in abrupt decreases in stream flow. A rapid rate of drawdown generally prevents the establishment of new willow, cottonwood, and other riparian tree and shrub species. Water diversions upstream of the Project area have caused substantial loss of riparian vegetation in several reaches of the river (e.g., Reaches 2 and 4A), and urban and agricultural development have caused a gradual loss in the area available for riparian habitat (Reclamation 1998a).

6.1.2 Project Setting

The Project area includes Reach 2B and a small portion of Reach 3, situated along approximately 12 miles of the San Joaquin River from the Chowchilla Bifurcation Structure to 2 miles downstream of Mendota Dam. Figure 1-2 of Chapter 1.0, "Introduction," includes a map of the Project area.

The river reach within the Project area consists primarily of a sandy river channel constricted by levees on both sides. The river is lined with narrow bands of riparian vegetation that extend from sparse and narrow riparian terraces to the top of the levees. Until the recently implemented Interim Flow regime, the portion of the Project area upstream of San Mateo Avenue was dry most of the year and the portion downstream was inundated by Mendota Pool.

Vegetation Alliances

Riparian vegetation types on levee banks, narrow terraces, small floodplains, and within the active channel include:

- Riparian forests and woodlands.
- Riparian thickets.
- Riparian scrub.
- Grasslands and herbaceous fields.
- Marshes and wet meadows.

These general vegetation types are subdivided into vegetation alliances based on the predominant species present. Table 6-1 provides a cross-reference between the special-status vegetation alliances recognized by the California Department of Fish and Wildlife (DFW) (2009) and found in the Project area, the former sensitive natural community types (DFW 2003), and plant community types (Holland 1986) used to classify vegetation in California. For the purpose of this document, special-status vegetation alliances are defined as natural communities that are considered vulnerable, imperiled, or critically imperiled, in California (State ranks 1-3 and riparian and wetland alliances). DFW currently requires that the vegetation alliance nomenclature based on the current system be used when evaluating project impacts (DFW 2009, Hickson 2009). Most types of wetlands and riparian communities are considered special-status vegetation alliances due to their limited distribution in California.

Table 6-1.
Cross-Reference of Vegetation Alliance, Natural Community, and Plant Community Types

Vegetation Alliance Common/ Scientific Name (DFW 2009)	Natural Community (DFW 2003)	Plant Community (Holland 1986)
Riparian Forest and Woodland Vegetation Alliances		
Fremont cottonwood forest/ *Populus fremontii* alliance	Fremont Cottonwood Riparian Forests and Woodlands	Cottonwood Riparian Forest
Oregon ash groves/ *Fraxinus latifolia* forest alliance	Oregon Ash Riparian Forest	Mixed Riparian Forest
Valley oak woodland/ *Quercus lobata* woodland alliance	Valley Oak Forests and Woodlands	Valley Oak Riparian Forest
Riparian Thicket Alliances		
Black willow thickets/ *Salix gooddingii* alliance	Black Willow Riparian Forests and Woodlands	Willow Riparian Forest
Buttonwillow thickets/ *Cephalanthus occidentalis* alliance	Buttonbush Scrub	Riparian Scrub
Red willow thickets/ *Salix laevigata* woodland alliance	Red Willow Riparian Forests	Willow Riparian Forest
Arrow weed thickets/ *Pluchea sericea* shrubland alliance	Arrow Weed Scrubs	Riparian Scrub
Riparian Scrub Alliances		
Blue elderberry stands/ *Sambucus nigra* shrubland alliance	Elderberry Scrub and Savanna	Elderberry Savanna
California rose briar patches/ *Rosa californica* alliance	California Rose Riparian Scrub	Riparian Scrub

Grassland and Herbaceous Field Alliances		
Tar plant fields/ *Centromadia pungens* or other species herbaceous alliance	Tar Plant Fields	Grassland and Pasture
Creeping rye grass turfs/ *Leymus triticoides* herbaceous alliance	Creeping Ryegrass Grassland	Grassland and Pasture
Salt grass flats/ *Distichlis spicata* herbaceous alliance	Saltgrass	Emergent Wetland
Marsh and Wet Meadow Alliances		
California bulrush marsh/ *Schoenoplectus californicus* herbaceous alliance	California Bulrush Wetland	Emergent Wetland
Pale spike rush marshes/ *Eleocharis macrostachya* herbaceous alliance	Spikerush	Emergent Wetland
Yerba mansa meadows/ *Anemopsis californica* herbaceous alliance	Alkali Meadow	Alkali Sink
Alkali heath marsh/ *Frankenia salina* alliance	Alkali Heath Dwarf Scrub	Alkali Sink

Table 6-2 below lists special-status vegetation alliances observed in the Project area, their extent, and vegetation alliance state ranking. DFW ranks vegetation alliances based on their rarity, vulnerability to disturbance, and association with sensitive habitat types such as streams and wetlands.

Table 6-2.
Special-Status Vegetation Alliances in the Project Area

Common Name	Scientific Name	State Rank	Area (acres)
Riparian Forest and Woodland Alliances			
Fremont cottonwood forest	*Populus fremontii* alliance	S3.2/Riparian	90.9
Oregon ash groves	*Fraxinus latifolia* forest alliance	S3.2/Riparian	7.1
Valley oak woodland	*Quercus lobata woodland* alliance	S3 to S2	0.2
Riparian Thicket Alliances			
Black willow thickets	*Salix gooddingii* alliance	S3/Riparian	146.8
Buttonwillow thickets	*Cephalanthus occidentalis* alliance	S2/Riparian	1.6
Red willow thickets	*Salix laevigata* woodland alliance	S3/Riparian	0.6
Arrow weed thickets	*Pluchea sericea* shrubland alliance	S3/Wetland	0.4
Riparian Scrub Alliances			
Blue elderberry stands	*Sambucus nigra* shrubland alliance	S3	76.4
California rose briar patches	*Rosa californica* alliance	S3/Riparian	13.4
Spinescale scrub	*Atriplex spinifera* alliance	S3	0.7
Silver bush lupine scrub	*Lupinus albifrons* shrubland alliance	S4	4.1
Grassland and Herbaceous Field Alliances			
Tar plant fields	*Centromadia pungens* or other species herbaceous alliance	S2	35.4
Creeping rye grass turfs	*Leymus triticoides* herbaceous alliance	S3/Riparian	6.2
Salt grass flats	*Distichlis spicata* herbaceous alliance	S4/Wetland	2.3
Marsh and Wet Meadow Alliances			
California bulrush marsh	*Schoenoplectus californicus* herbaceous alliance	S4/Wetland	47.0
Pale spike rush marsh	*Eleocharis macrostachya* herbaceous alliance	S4/Wetland	1.6
Yerba mansa meadows	*Anemopsis californica* herbaceous alliance	S2/Wetland	0.8
Alkali heath marsh	*Frankenia salina* alliance	S3/Wetland	0.7

Vegetation Alliance State Ranking by DFW:
S1 = statewide critically imperiled
S2 = statewide imperiled
S3 = statewide vulnerable
S3.2 = vulnerable and threatened – at moderate risk of extinction or elimination in the State due to a restricted range, relatively few populations, recent and widespread declines, or other factors.
S4 = statewide apparently secure
S5 = secure

Riparian Forest and Woodland

Riparian forest and woodland alliances in the Project area include Fremont cottonwood forest, Oregon ash groves, and valley oak woodland.

Fremont cottonwood forest (*Populus fremontii* alliance) is a multilayered riparian forest occurring on high floodplain areas along the San Joaquin River. Older and decadent stands of cottonwood riparian forest also exist in areas that were formerly active floodplains, but are now on functional terraces because of the reduction in high flow regime following the completion of Friant Dam. Fremont cottonwood forests are typically up to 80 feet tall and the canopy cover is open in woodlands to continuous in forests. Fremont cottonwood is the dominant or co-dominant species in the tree canopy with other trees such as Oregon ash (*Fraxinus latifolia*), California black walnut (*Juglands californica*), California sycamore (*Platanus racemosa*), and black willow (*Salix gooddingii*). California wild grape (*Vitis californica*) is a conspicuous vine usually growing within the canopy of Fremont cottonwoods. The mid-story is typically dominated by open to intermittent shade-tolerant shrubs and small trees. Other shrubby species of willow such as sandbar willow (*Salix exigua*) may also be present within the mid-story along the sunny edges of the forest. The understory is typically dominated by native grasses and forbs, such as creeping wildrye (*Leymus triticoides*), stinging nettle (*Urtica dioica* ssp. *holosericea*), and at the lower mesic edges, Santa Barbara sedge (*Carex barbarae*). Fremont cottonwood forest occurs on 66 acres in the Project area.

Oregon ash groves (*Fraxinus latifolia* forest alliance) occur where Oregon ash is the dominant or co-dominant species in the tree canopy with other riparian trees. Oregon ash groves are typically up to 50 feet tall and the canopy cover is open to continuous. Shrubs are sparse to intermittent because of heavy shade under the dense canopy. The herbaceous layer is sparse and variable. The alliance occurs on terraces and levee slopes with alluvial soils in the Project area.

Valley oak woodlands (*Quercus lobata* woodland alliance) have valley oak as the dominant or co-dominant tree. Although this alliance was found in the Project area, only individual trees were observed and these were possibly planted. The alliance occurs on the south side of Mendota Pool in soils that may be seasonally saturated or intermittently flooded during very high flows.

Riparian Thickets

Riparian thicket vegetation alliances in the Project area include black willow thickets, buttonwillow thickets, red willow thickets, and arrow weed thickets.

Black willow thickets (*Salix gooddingii* alliance) have black willow as the dominant or co-dominant species in the tree canopy with other trees such as white alder, Fremont cottonwood, red willow, arroyo willow, shining willow and yellow willow (*Alnus rhombifolia, Populus fremontii, Salix laevigata, S. lasiolepis, S. lucida* ssp. *lasiandra,* and *S. lutea*). In the Project area, black willow thickets are typically up to 60 feet tall and the alliance canopy cover is open to continuous. Shrubs are open to continuous with blue elderberry (*Sambucus nigra*), coyote brush (*Baccharis pilularis*), and mulefat (*B.*

salicifolia). The alliance occurs in riparian corridors, rocky floodplains, small intermittent streams, springs, and seeps.

Buttonwillow thicket (*Cephalanthus occidentalis* alliance) is a vegetation alliance where buttonwillow shrubs are dominant in the canopy or co-dominant with black willow, shining willow (*S.lucida* ssp. *lasiandra*), and sandbar willow (*S. exigua*). Buttonwillow shrubs are typically less than 20 feet tall and the alliance provides open, intermittent, or continuous canopy cover. The herbaceous understory layer is sparse or grassy. The alliance occurs in seasonally flooded basins with slowly moving or stagnant water and in floodplains with subsurface water at the end of the growing season. Many small stands of buttonwillow occur on the lower margins of the levee banks throughout most of the Project area and these stands often form narrow strips along levees.

Red willow thicket (*Salix laevigata* woodland alliance) is a vegetation alliance where red willow is the dominant or co-dominant in the tree canopy with other trees. In the Project area, these can be Fremont cottonwood, black willow, and blue elderberry. Red willow thickets are up to 70 feet tall and the alliance canopy cover is open to continuous. The shrub layer is open to continuous. The alliance occurs in the Project area only sparsely with other riparian trees on floodplains and low-gradient depositions along the river.

Arrow weed thickets (*Pluchea sericea* shrubland alliance) have arrow weed as the dominant or co-dominant species with other plants in the shrub canopy. In the Project area, they can be mulefat, sandbar willow, and dogbane. The alliance occurs along stream borders or seasonally flooded areas. Arrow weed is a wetland plant. Several large areas of this vegetation alliance were observed in the Project area in low-lying areas that are seasonally flooded on the south bank in the meander loop between River Mile (RM) 207 and RM 208.

Riparian Scrub

Riparian scrub alliances in the Project area include the blue elderberry stands, California rose briar patches, and spinescale scrub vegetation alliances.

Blue elderberry stands (*Sambucus nigra* shrubland alliance) have blue elderberry as the dominant or co-dominant species in the shrub canopy with other shrubs such as mugwort, coyote brush, mulefat, toyon, tobacco tree, sandbar willow, poison oak and California grape. Emergent trees, such as California walnut, Fremont cottonwood, and Oregon ash may occur. In the Project area, blue elderberry stands are typically up to 20 feet tall and the canopy cover is open. The herbaceous layer is variable and usually grassy. The alliance occurs primarily on levee banks and in meander loop bottomlands. The blue elderberry is especially abundant in the southeast, undeveloped pastures of the Project area and in the meander loops between RM 213 and RM 216 near the Chowchilla Bifurcation Structure. The alliance occurs on sand and gravelly soil alluvium that is intermittently flooded. Blue elderberry shrubs in the Project area are habitat for the Federally-listed, threatened valley elderberry longhorn beetle.

California rose briar patches (*Rosa californica* alliance) have California rose as the dominant or co-dominant species in the shrub canopy with other shrubs such as coyote

brush, sandbar willow, blue elderberry, and mulefat. California rose briar patches are typically up to 7 feet tall and the cover is typically very dense and continuous. The herbaceous layer is open and sparse because of heavy shading. The alliance occurs on levee banks throughout the reach on soils that are either mixed coarse alluvium or levee import.

Spinescale scrub *(Atriplex spinifera* alliance) has spinescale as the dominant or co-dominant species in the shrub canopy with other shrubs such as alkali heath (*Frankenia salina)* or mulefat. Spinescale scrub is typically up to 7 feet tall and the canopy cover is open. The herbaceous layer is variable with seasonal annuals reaching high cover. The alliance is scattered in several sandy areas high above the current water surface.

Grasslands and Herbaceous Fields

Grassland and herbaceous field alliances in the Project area include tar plant fields, creeping rye grass turfs, and salt grass flats.

Tarplant fields (*Centromadia pungens* herbaceous alliance) have tarplant as dominant to conspicuous in the herbaceous layer. Tarplant is typically lower than 2 feet and the cover is intermittent to continuous. The alliance occurs in vernally wet habitats, including alkaline flats subjected to periodic or intermittent water inundation. It is common in and near the meander loop between RM 207 and RM 208 that is now typically flooded in the winter. It occurs here on soils that are finer-textured, silty alluvium that is poorly drained. Common tarplant often covers large areas.

Creeping rye grass turfs (*Leymus triticoides* herbaceous alliance) has creeping rye as the dominant or co-dominant species in the herbaceous layer with other herbs such as yerba mansa (*Anemopsis californica*), salt grass (*Distichlis spicata*), and barley grasses (*Hordeum* species) on poorly drained floodplains, moderately moist flat to sloping topography, levee slopes and marsh margins.

Salt grass flats (*Distichlis spicata* herbaceous alliance) has salt grass is the dominant or co-dominant species in the herbaceous layer with other herbs such as yerba mansa, creeping rye, alkali heath, and barley grasses on poorly drained floodplains, wet meadows, and marsh margins.

Marsh and Wet meadow

Marsh and wet meadow alliances include California bulrush marsh, pale spike rush marsh, yerba mansa meadow and alkali heath marsh.

California bulrush marsh (*Schoenoplectus californicus* herbaceous alliance) has California bulrush as the dominant species. It occurs with hardstem bulrush (*Scirpus acutus*), broadleaf cattail (*Typha latifolia*), narrowleaf cattail (*Typha angustifolia*), and river bulrush (*Scirpus fluviatilis*). It is an emergent species that occurs along the edges of Mendota Pool. It also forms numerous vegetation islands in low velocity reaches of the river.

Pale spike rush marsh (*Eleocharis macrostachya* herbaceous alliance) is a vegetation alliance where pale spike rush is the dominant species.

Yerba mansa meadows (*Anemopsis californica* herbaceous alliance) have yerba mansa as dominant or co-dominant with other herbaceous species such as alkali heath (*Frankenia grandiflora*), salt grass (*Distichlis spicata*), western goldenrod (*Euthamia occidentalis*), prickly lettuce (*Lactuca serriola*), and creeping rye grass (*Leymus triticoides*). Yerba mansa meadows occur on alkaline or saline soils on stream terraces and floodplains adjacent to the river. Yerba mansa is a wetland plant that almost always occurs in wetland areas. The alliance was observed in well preserved riparian meadows on the south bank of the river in areas where the river backs up behind Mendota Dam.

Alkali heath marsh (*Frankenia salina* alliance) has alkali heath as the dominant or co-dominant species in the herbaceous or subshrub layer with other species such as salt grass *(Distichlis spicata*) and creeping rye grass (*Leymus triticoides*). Alkali heath marsh is typically composed of herbs and subshrubs up to 2 feet tall and the alliance canopy cover is open to continuous. In the Project area, it occurs on soils that are typically alkaline, saline, sandy to clayey alluvium.

Special-Status Plants

Special-status plant species include those that meet any one of the following definitions:

- Listed or candidates for listing under the Federal Endangered Species Act (ESA) (50 Code of Federal Regulations [CFR] §17.12).
- Listed or candidates for listing by the State as threatened or endangered under the California Endangered Species Act (CESA) (Fish & G. Code, § 2050 et seq.).
- Listed as rare under the California Native Plant Protection Act (CNPPA) (Fish & G. Code, § 1900 et seq.).
- Species considered by the California Native Plant Society (CNPS) to be "rare, threatened or endangered in California" (Lists 1A, 1B and 2).
- Other plant species that are considered by the scientific community to meet the definition of rare or endangered plants under the California Environmental Quality Act (CEQA) section 15380.

Special-status plant species evaluated for the potential to occur in the Project area are listed in Table 6-3. The table includes field survey results and an evaluation of the potential for the species to occur in the portions of the Project area that were not accessible for field surveys. Table 6-3 includes an assessment of potential for special-status plants to occur in these areas based on generally known habitat characteristics and the range and distribution of plant species. No special-status plant species were identified during field surveys.[1]

[1] Special-status plant surveys took place from August 2010 through July 2011 where access had been granted in the Project area. Detailed vegetation alliance surveys were conducted on December 15, 2009, and on May 19, 2010.

Table 6-3.
Federal-, State-, or CNPS-Listed Plant Species with a Potential to Occur in the Project Area

Scientific Name **Common Name**	**Federal/ State/ CNPS Status**	**Habitat/ Communities**	**Potential to Occur in inaccessible Project Areas and Survey Results**	**Blooming Period/ Survey Date**
Atriplex cordulata heartscale	--/--/1B.2	Chenopod scrub, meadows and seeps, and sandy/saline or alkaline valley and foothill grassland	Moderate potential to occur based on marginal habitat, disturbance, and reported observations within 5 miles of the Project area Not observed during surveys.	Apr-Oct/ late April
Atriplex depressa brittlescale	--/--/1B.2	Chenopod scrub, meadows and seeps, playas, valley and foothill grassland, and alkaline or clay vernal pools	Moderate potential to occur based on marginal habitat, disturbance, and reported observations within 10 miles of the Project area Not observed during surveys.	Apr-Oct/ late April
Atriplex minuscula lesser saltscale	--/--/1B.1	Chenopod scrub, playas, and alkaline or sandy valley and foothill grassland	Moderate potential to occur based on absence during accessible area surveys, little suitable habitat & disturbance. However, CNDDB observations within 10 miles of the Project area. Not observed during surveys.	May-Oct/ mid-June
Atriplex persistens vernal pool smallscale	--/--/1B.2	Alkaline vernal pools	Low potential to occur based on absence during accessible area surveys, no alkaline vernal pools & disturbance. However, CNDDB observations within 10 miles of the Project area. Not observed during surveys.	Jun-Oct/ mid-June
Atriplex subtilis subtle orache	--/--/1B.2	Valley and foothill grassland	Moderate potential to occur based on absence during accessible area surveys, little suitable habitat & disturbance. However, CNDDB observations within 5 miles of the Project area. Not observed during surveys.	Jun-Aug (Oct*) *uncommon /mid-June
Atriplex vallicola Lost Hills crownscale	--/--/1B.2	Chenopod scrub, valley and foothill grassland, and alkaline vernal pools	Moderate potential to occur based on absence during accessible area surveys, little suitable habitat & disturbance. However, CNDDB observations within 5 miles of the Project area. Not observed during surveys.	Apr-Aug/ late April

Table 6-3.
Federal-, State-, or CNPS-Listed Plant Species with a Potential to Occur in the Project Area

Scientific Name **Common Name**	**Federal/ State/ CNPS Status**	**Habitat/ Communities**	**Potential to Occur in inaccessible Project Areas and Survey Results**	**Blooming Period/ Survey Date**
Castilleja campestris ssp. *succulenta* succulent owl's-clover	FT/SE/1B.2	Vernal pools (often acidic)	Very low potential to occur based on absence during accessible area surveys, no suitable habitat & disturbance. Some potential based on elevation. Not observed during surveys.	Apr-May/ late April
Caulanthus californicus California jewel-flower	FE/SE/1B.1	Chenopod scrub, pinyon and juniper woodland, and sandy valley and foothill grassland	Very low potential to occur based on absence during accessible area surveys, little suitable habitat & disturbance. Not observed during surveys.	Feb-May/ mid-March
Cordylanthus palmatus palmate-bracted bird's-beak	FE/SE/1B.1	Chenopod scrub and alkaline valley and foothill grassland	Low potential to occur based on absence during accessible area surveys, little suitable habitat & disturbance. However, CNDDB observations within 5 miles of the Project area. Not observed during surveys.	May-Oct/ mid-June
Delphinium recurvatum recurved larkspur	--/--/1B.2	Chenopod scrub, cismontane woodland, and alkaline valley and foothill grassland	Low potential to occur based on absence during accessible area surveys, little suitable habitat, & disturbance. However, CNDDB observations within 10 miles of the Project area. Not observed during surveys.	Mar-Jun/ mid-March
Imperata brevifolia California satintail	--/--/2.1	Chaparral, coastal scrub, Mojavean desert scrub, meadows and seeps (often alkali), and mesic riparian scrub	Low potential to occur based on absence during accessible area surveys, little suitable habitat & disturbance. Elevation is suitable. Not observed during surveys.	Sep-May/ mid-March
Layia munzii Munz's tidy tips	--/--/1B.2	Chenopod scrub and alkaline clay valley and foothill grassland	Moderate potential to occur based on absence during accessible area surveys, little suitable habitat & disturbance. However, CNDDB observations within 5 miles of the Project area. Not observed during surveys.	Mar-Apr/ mid-March

Table 6-3.
Federal-, State-, or CNPS-Listed Plant Species with a Potential to Occur in the Project Area

Scientific Name **Common Name**	**Federal/ State/ CNPS Status**	**Habitat/ Communities**	**Potential to Occur in inaccessible Project Areas and Survey Results**	**Blooming Period/ Survey Date**
Leptosiphon serrulatus Madera leptosiphon	--/--/1B.2	Cismontane woodland and lower montane coniferous forest	No potential to occur based on absence during accessible area surveys, no suitable habitat, lower elevation & disturbance. Not observed during surveys.	Apr-May/ late April
Monolopia congdonii San Joaquin woollythreads	FE/--/1B.2	Chenopod scrub and sandy valley and foothill grassland	Moderate potential to occur based on absence during accessible area surveys & disturbed habitat. However, CNDDB observations within 10 miles of the Project. Not observed during surveys.	Feb-May/ mid-March
Orcuttia inaequalis San Joaquin Valley Orcutt grass	FT/SE/1B.1	Vernal pools	Very low potential to occur based on absence during accessible area surveys, no vernal pools & disturbance. Not observed during surveys.	Apr-Sep/ late April
Orcuttia pilosa hairy Orcutt grass	FE/SE/1B.1	Vernal pools	Very low potential to occur based on absence during accessible area surveys, no vernal pools & disturbance. Not observed during surveys.	May-Sep/ mid-June
Sagittaria sanfordii Sanford's arrowhead	--/--/1B.2	Assorted shallow freshwater marshes and swamps	Moderate potential to occur based on absence during accessible area surveys & disturbance. However, CNDDB observations within 5 miles of the Project area and suitable habitat. Not observed during surveys.	May-Oct/ mid-June
Tropidocarpum capparideum caper-fruited tropidocarpum	--/--/1B.1	Alkaline hills valley and foothill grassland	Low potential to occur based on absence during accessible area surveys, little suitable habitat & disturbance. Not observed during surveys.	Mar-Apr/ mid-March

Key:
CNDDB = California Natural Diversity Database
FE = federally endangered
SE = State endangered
1B.1 = California Rare Plant Rank 1B (rare, threatened, or endangered plant), seriously threatened in California
1B.2 = California Rare Plant Rank 1B (rare, threatened, or endangered plant), fairly threatened in California
2.1 = California Rare Plant Rank 2 (rare, threatened, or endangered in California, but more common elsewhere)
-- = not listed

Non-Native Invasive Plants

Non-native invasive plants are species that are not native to the region, persist without human assistance, and adversely affect areas where they colonize because they outcompete or exclude more desirable native species, reduce agricultural productivity, or have other impacts (Davis and Thompson 2000). The term "invasive plant" differs from the classification terms "nonnative," "exotic," or "introduced plant" because it describes those non-native plant species that displace native species on a large enough scale to alter habitat functions and values. The California Invasive Plant Council (Cal-IPC) maintains a list of non-native invasive plant species considered invasive in California. The term "noxious weed" is used by government agencies for non-native plants that have been defined as pests in agriculture by law or regulation (California Department of Food and Agriculture [CDFA] 2012). Many invasive noxious trees and shrubs that have the ability to occupy channel and floodplain surfaces threaten river floodway capacity, and substantial cost and resources are required to remove and control large infestations.

Invasive plant species may interfere with the success of Restoration actions because of their ability to rapidly colonize new habitats and prevent the establishment of desirable native vegetation. Field surveys identified several invasive plant species in the Project area. Table 6-4 lists these species and indicates the degree of their invasiveness based on CDFA and Cal-IPC criteria. Of the invasive plant species observed in the Project area, the following have a Cal-IPC high rating (indicating a potential for severe ecological impacts): barbed goatgrass, giant reed, red brome, cheatgrass, yellow-star thistle, English ivy, broad-leafed pepper, Himalayan blackberry, small-flower tamarisk, saltcedar, and spotted knapweed. The following invasive plant species were also observed nearby or upstream and have a Cal-IPC high rating: red sesbania, water hyacinth, and spongeplant.

Table 6-4.
Invasive Plant Species Observed in the Project Area

Scientific Name	Common Name	Invasiveness
Acroptilon repens	Russian knapweed	CDFA List B, Cal-IPC moderate
Aegilops triuncialis	barb goatgrass	CDFA List B, Cal-IPC high
Ailanthus altissima	tree-of-heaven	Cal-IPC moderate
Arundo donax	giant reed	Cal-IPC high
Atriplex semibacchata	Australian saltbush	Cal-IPC moderate
Avena barbata	slender wild oats	Cal-IPC moderate
Avena fatua	common wild oats	Cal-IPC moderate
Brassica nigra	black mustard	Cal-IPC moderate
Bromus diandrus	ripgut brome	Cal-IPC moderate
Bromus madritensis ssp. *rubens*	red brome	Cal-IPC high
Bromus tectorum	downy brome, cheatgrass	Cal-IPC high
Carduus pycnocephalus	Italian thistle	CDFA List C, Cal-IPC moderate
Centaurea maculosa	spotted knapweed	CDFA List A, Cal-IPC high
Centaurea solstitialis	yellow-star thistle	CDFA List C, Cal-IPC high
Cirsium vulgare	bull thistle	Cal-IPC moderate
Conium maculatum	poison hemlock	Cal-IPC moderate
Cynara cardunculus	artichoke thistle, cardoon	Cal-IPC moderate

Table 6-4.
Invasive Plant Species Observed in the Project Area

Scientific Name	Common Name	Invasiveness
Cynodon dactylon	Bermuda grass	Cal-IPC moderate
Ficus carica	edible fig	Cal-IPC moderate
Hedera helix	English ivy	Cal-IPC high
Hirschfeldia incana	Mediterranean hoary mustard	Cal-IPC moderate
Hordeum murinum ssp. *murinum*	foxtail barley	Cal-IPC moderate
Lepidium latifolium	broad-leafed pepper (i.e., perennial pepperweed)	CDFA List B, Cal-IPC high
Lolium multiflorum	Italian rye grass	Cal-IPC moderate
Lotus corniculatus	birdsfoot treefoil	Cal-IPC moderate
Lythrum hyssopifolium	hyssop loosestrife	Cal-IPC moderate
Mentha pulegium	pennyroyal	Cal-IPC moderate
Nicotiana glauca	tree tobacco	Cal-IPC moderate
Oxalis pes-caprae	Bermuda buttercup	Cal-IPC moderate
Phalaris aquatica	Harding grass	Cal-IPC moderate
Rubus discolor	Himalayan blackberry	Cal-IPC high
Rumex acetosella	sheep sorrel	Cal-IPC moderate
Sisymbrium irio	London rocket	Cal-IPC moderate
Tamarix parviflora	small-flower tamarisk	Cal-IPC high
Tamarix pentandra	saltcedar	Cal-IPC high
Torilis arvensis	hedge parsley	Cal-IPC moderate
Vulpia myuros	rattail fescue	Cal-IPC moderate
Washingtonia robusta	Washington fan palm	Cal-IPC moderate

Key:
Cal-IPC = California Invasive Plant Council
CDFA = California Department of Food and Agriculture
Cal-IPC high = severe ecological impacts on physical processes, plant and animal communities, and vegetation structure.
Cal-IPC moderate = substantial and apparent ecological impacts on physical processes, plant and animal communities, and vegetation structure
CDFA List A = either not known to be established in the State or is present in a limited distribution; recommended for exclusion and eradiacation
CDFA List B = widely distributed in some regions of the State; recommended for regional eradication
CDFA List C = widespread throughout the State; recommended for local eradication

6.2 Regulatory Setting

Federal, State, and local laws and regulations applicable to vegetation in the Project area include ESA, National Environmental Policy Act (NEPA), CESA, CEQA, CNPPA, which cover impacts to natural vegetation, sensitive communities, and rare plants, and Public Resources Code section 21083.4, which covers oak woodlands conservation and directs counties to describe and mitigate impacts to oak woodlands.

6.2.1 Federal

Federal Endangered Species Act of 1973 (50 CFR Part 17)

The ESA defines special-status plants as species listed or proposed for listing as threatened or endangered under the ESA, or candidates for possible future listing as threatened or endangered under the ESA (50 CFR §17.12).

Recovery Plan for Upland Species of the San Joaquin Valley, California

The Recovery Plan for Upland Species of California was released by U.S. Fish and Wildlife Service (USFWS) on September 30, 1998. This plan focuses on 34 species of plants and animals that occur in the San Joaquin Valley and that are either Federally-listed as threatened or endangered or are candidates for Federal listing or species of concern. The ultimate goal of the recovery plan is to delist the 11 endangered and threatened species addressed in the plan and ensure the long-term conservation of the other 23 species (USFWS 1998). The plan provides for both an ecosystem approach and a community-level strategy. While not regulatory in nature, the Recovery Plan would be taken into consideration when analyzing potential impacts on upland natural community habitats in the San Joaquin Valley to ensure that projects do not prevent or impair the plan's future long-term implementation success. It is also used by the USFWS to determine recommendations and requirements during endangered species consultation for these species.

Invasive Species (Executive Order 13112)

Executive Order 13112 requires Federal agencies to perform measures to minimize the spread of invasive species and to reintroduce native species where possible. This order applies to "actions that may affect the status of invasive species" (Section 2). Federal agencies must pursue the duties mandated under the order in consultation with the Invasive Species Council (Section 2(b)). The order also requires agencies to formulate their own Invasive Species Management Plan (Section 5).

6.2.2 State of California

Vegetation Alliances

DFW and its collaborators use a suite of factors to assess the conservation ranking of vegetation alliances. All California vegetation alliances are described, ranked, and assembled into a list. DFW then issues the ranked list of California vegetation alliances for the public's use, for California Natural Diversity Database (CNDDB) mapping efforts, and for project impact assessment. The current version of the List of California Vegetation Alliances was released in December 2009 (DFW 2009).

Conservation ranks in this list provide an estimate of the risk of elimination for vegetation alliances. They are based on a one to five scale rank (NatureServe Explorer 2009), ranging from critically imperiled (1) to demonstrably secure (5). Status is assessed and documented at three distinct geographic scales of the assessment (G = Global, N = National, and S = Subnational or State).

For the purpose of this document, special-status vegetation alliances (sensitive plant communities) are defined as natural communities that are of limited distribution statewide or within a county or region and are often vulnerable to environmental impacts of projects. The current version of the List of California Vegetation Alliances (DFW 2009) indicates vegetation alliances of high inventory priority for conservation status, which are those globally or State ranked 1-3 (critically imperiled, imperiled and vulnerable). Most types of wetlands and riparian communities are considered special-status vegetation alliances due to their limited distribution in California. These high-priority vegetation alliances often contain special-status plants.

Special-Status Plants

California laws and regulations define special-status plants as those:

- Listed or candidates for listing by the State as threatened or endangered under CESA (Fish & G. Code, § 2050 et seq.).
- Listed as rare under CNPPA (Fish & G. Code, § 1900 et seq.).
- Meet the definition of rare or endangered under CEQA § 15380, subds. (b) and (d).

California Endangered Species Act (Fish & G. Code, § 2050 et seq.) CESA defines special-status plants as species that are listed or are candidates for listing by the State as threatened or endangered under CESA (Fish & G. Code, § 2050 et seq.). A species, subspecies, or variety of plant is endangered when the prospects of its survival and reproduction in the wild are in immediate jeopardy from one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, disease, or other factors (Fish & G. Code, § 2062). A plant is threatened when it is likely to become endangered in the foreseeable future in the absence of special protection and management measures (Fish & G. Code, § 2067).

California Native Plant Protection Act (Fish & G. Code, § 1900 et seq.) The CNPPA is intended to preserve, protect, and enhance endangered or rare native plants in the State. The CNPPA defines special-status plants as those listed as rare under CNPPA (Fish & G. Code, § 1900 et seq.). A plant is rare when, although not presently threatened with extinction, the species, subspecies, or variety is found in such small numbers throughout its range that it may be endangered if its environment worsens (Fish & G. Code, § 1901).

California Environmental Quality Act section 15380, subdivisions (b) and (d). CEQA defines special-status plants as those that meet the definition of rare or endangered under CEQA section 15380, subdivisions (b) and (d). Species that may meet the definition of rare or endangered include the following:

- Species considered by CNPS to be “rare, threatened or endangered in California” (Lists 1A, 1B and 2).
- Species that may warrant consideration on the basis of local significance or recent biological information.

- Some species included on the CNDDB Special Plants, Bryophytes, and Lichens List (DFW 2015).

California Native Plant Society Species Designations. CNPS is a statewide nonprofit organization that seeks to increase understanding of California's native flora, and to preserve this rich resource for future generations. CNPS has developed and maintains lists of vascular plants of special concern in California. CNPS-listed species have no formal legal protection, but the value and importance of these lists are widely recognized. CNPS List 1 and 2 species are considered rare plants pursuant to section 15380 of CEQA, and it is recommended that they be fully considered while preparing environmental documents relating to CEQA.

6.2.3 Regional and Local

Regional and local regulations or protected plant lists may define special-status plant species that could meet the definition of rare or endangered plants under CEQA section15380. Regional and local plans and policies pertaining to vegetation are discussed below.

Riparian Habitat Joint Venture

The Riparian Habitat Joint Venture (RHJV) was initiated in 1994 and includes signatories from 18 Federal, State, and private agencies. The RHJV promotes conservation and the restoration of riparian habitat to support native bird populations through three goals:

- Promote an understanding of the issues affecting riparian habitat through data collection and analysis.
- Double riparian habitat in California by funding and promoting on-the-ground conservation projects.
- Guide land managers and organizations to prioritize conservation actions.

RHJV conservation and action plans are documented in the Riparian Bird Conservation Plan (RHJV 2004). The conservation plan targets 14 "indicator" species of riparian-associated birds and provides recommendations for habitat protection, restoration, management, monitoring, and policy. The report notes habitat loss and degradation as one of the most important factors causing the decline of riparian birds in California.

County Plans

Pertinent county plans include the Fresno and Madera county general plans.

Fresno County General Plan

The Fresno County General Plan was updated in October 2000. In the Project area and vicinity, Fresno County's land use jurisdiction lies south and west of the San Joaquin River centerline, through Reaches 1, 2, and 3, and into Reach 4A. The general plan identifies 27 primary land use designations (defined in terms of allowable uses and intensity standards) and three overlay designations (an overlay land use designation modifies the policies, standards, or procedures established for the underlying primary

land use designation). One of the three overlay designations is for the San Joaquin River corridor.

The general plan also identifies as a priority the protection and enhancement of water quality and quantity in Fresno County's streams, creeks, and groundwater basins through the protection of floodplain lands.

Policies in the general plan seek to protect natural areas, particularly riparian and wetland habitats, in the county, and to preserve habitat diversity in Fresno County through restoring and enhancing habitats that support fish and wildlife species so that populations are maintained at viable levels. Notably, the general plan seeks to preserve and enhance the San Joaquin River corridor areas adjoining the county's river corridor by avoiding adverse impacts from development and encouraging environmentally friendly recreational and agricultural activities. One policy in the general plan directs the county to require riparian protection zones around natural watercourses, recognizing that these areas provide highly valuable wildlife habitat. Another policy recommends the acquisition (through fee acquisition or protective easements, often in cooperation with other local, State, and Federal agencies and private entities) of creek corridors, wetlands, and areas rich in wildlife, or of a fragile ecological nature as public open space where such areas cannot be effectively preserved through the regulatory process. The general plan prioritizes the protection of wetlands, riparian habitat, and meadows because they are recognized as essential habitats for birds and wildlife, and it requires a minimum 200-foot-wide wildlife corridor along particular stretches of the San Joaquin River and Kings River, whenever possible.

Madera County General Plan Policy Document

The Madera County General Plan Policy Document, adopted in October 1995, is a stand-alone document that is part of the Madera County General Plan. In the Project area and vicinity, Madera County's land use jurisdiction lies northeast of the San Joaquin River centerline and continues downstream from Friant Dam through Reaches 1, 2, 3, and 4A.

One of the goals in the general plan is to protect and enhance the natural qualities of Madera County's streams, creeks, and groundwater, minimizing sedimentation and erosion of creeks and damage to riparian habitat. The general plan also prioritizes the protection of wetland communities and related riparian areas throughout Madera County as valuable resources, the protection of riparian zones around natural watercourses, and the conservation of remaining upland habitat areas adjacent to wetlands and riparian areas that are critical to the feeding or nesting of wildlife species associated with these wetland and riparian areas. One policy in the general plan directs the county to support the goals and policies of the San Joaquin River Parkway Master Plan to preserve existing habitat and maintain, enhance, or restore native vegetation to provide essentially continuous riparian and upland habitat for wildlife along the river between Friant Dam and the State Route (SR) 145 crossing.

The general plan also identifies a goal to protect, restore, and enhance habitats that support fish and wildlife species so as to maintain populations at viable levels, by protecting critical nesting and foraging areas, important spawning grounds, migratory

routes, waterfowl resting areas, oak woodlands, wildlife movement corridors, and other unique wildlife habitats critical to protecting and sustaining wildlife populations, and by ensuring the conservation of sufficiently large, continuous expanses of native vegetation to provide suitable habitat for maintaining abundant and diverse wildlife if this preservation does not threaten the economic well-being of the county. Another goal of the general plan is to preserve and enhance open space lands to maintain the natural resources of the county by supporting preservation and enhancement of natural land forms, natural vegetation, and natural resources (including wetland preserves, riparian corridors, woodlands, and floodplains) as open space. These open space and natural areas should be interconnected and of sufficient size to protect biodiversity, accommodate wildlife movement, and sustain ecosystems.

6.3 Environmental Consequences and Mitigation Measures

This section describes the effects that the Project Alternatives would have on special-status plants and vegetation alliances relative to the "No-Action conditions" in accordance with NEPA, and "existing conditions" based on CEQA requirements. The potential effects of each alternative are assessed with respect to significance criteria. Measures to avoid, minimize, or mitigate potential negative impacts are described. The Project Alternatives evaluated in this section are described in detail in Chapter 2.0, "Description of Alternatives." The potential impacts are summarized below.

6.3.1 Impact Assessment Methodology

Identification of Vegetation Resources in the Project Area

Existing biological resources were determined through review of scientific literature, existing data sources, and field surveys. Existing documents reviewed include:

- *Historical Riparian Habitat Conditions of the San Joaquin River — Friant Dam to the Merced River*, prepared by Jones & Stokes Associates, Inc. for U.S. Department of the Interior, Bureau of Reclamation (Reclamation), Fresno, California. April 1998 (Reclamation 1998a).
- *Analysis of Physical Processes and Riparian Habitat Potential of the San Joaquin River — Friant Dam to the Merced River*, prepared by Jones & Stokes Associates, Inc. for Reclamation, Fresno, California. October 1998 (Reclamation 1998b).
- *Riparian Vegetation of the San Joaquin River*, prepared by California Department of Water Resources (DWR) for Reclamation, May 2002 (DWR 2002).
- *San Joaquin River Restoration Study Background Report*, edited by McBain and Trush, December 2002 (McBain and Trush 2002).
- *Draft Mendota Pool Bypass and Reach 2B Improvements Project Technical Memorandum on Environmental Field Survey Results*, November 2011 (San Joaquin River Restoration Program [SJRRP] 2011a).

Permits to enter private property in the Project area to perform biological surveys were not obtained until summer of 2010, so biological fieldwork occurred in 2010 and 2011.

Field surveys were performed according to DFW protocol by walking those portions of the Project area where access was granted during the flowering period of special-status plants which had a potential to occur in the Project area. Plant species observed during field surveys are listed in *Mendota Pool Bypass and Reach 2B Improvements Project Technical Memorandum on Environmental Field Survey Results* (SJRRP 2011a, Attachment A). Species observed were identified to a level sufficient to determine their rarity status. These reviews and surveys provided the best available information about the biological resource condition closest to the baseline date.

Impact Evaluation Methodology

There were no special-status plants identified in the Project area. Therefore, the impact analysis focuses on vegetation alliances, and the potential impacts and beneficial effects on vegetation alliances that would result from implementing the Project Alternatives as compared to the No-Action Alternative and existing conditions.

The impact assessment is based on review and analysis of the following environmental concerns and topics:

- The extent and type of existing special-status vegetation alliances documented within the Project area that have the potential to be affected by the Project Alternatives.
- The quantity and quality of the special-status vegetation alliances proposed to be installed under the Project Alternatives and their development over time.
- The habitat requirements of special-status vegetation alliances under the Project Alternatives as compared to the No-Action Alternative and existing conditions.
- Long-term and temporary effects of the Project Alternatives.
- Direct, indirect, and cumulative effects of the Project Alternatives.
- Threats to special-status vegetation alliances including those from invasive plant species.
- The immediacy of potential effects.
- Recommended measures to avoid, minimize, or mitigate impacts.

Potential effects evaluated include direct, indirect, temporary, and long-term. Direct impacts include the direct removal or loss of vegetation within the footprint of ground disturbing actions. Indirect impacts are those incidental to Project implementation, such as changes in the hydrologic regime that results in different plant species establishment over time. Temporary impacts have a short duration and vegetation would be expected to recover or be restored within 3 to 5 years of Project implementation. An example would be the trimming and pruning of vegetation to install infrastructure, followed by vegetation re-growth. Long-term impacts involve the long-term alteration of vegetation or habitat such as the removal of mature trees or the conversion of backwater marsh area to active channel riparian habitat, resulting in permanent changes to vegetation type.

Key impact issues for special-status vegetation alliances are those that change vegetation health or survival. Where possible, impacts of stress are differentiated from impacts

resulting directly or indirectly in the mortality of riparian vegetation. Assumptions used in the impact assessment include:

- The distribution and abundance of special-status vegetation alliances would be proportional to the amount and quality of habitat available.
- Direct and indirect habitat modifications would reach maturity by the end of the planning horizon of the Project (2035).
- Site evolution would allow some habitats to form immediately or within several years of construction.
- Control and management of non-native invasive plant species would be implemented throughout the duration of Project construction and monitoring.

6.3.2 Significance Criteria

State CEQA Guidelines Appendix G and NEPA Council on Environmental Quality (CEQ) Regulations were used to develop the significance criteria. Under NEPA CEQ Regulations, impacts must be evaluated in terms of their context and intensity. Effects may be beneficial or adverse. An example of a beneficial effect would be the conversion of non-native grassland to a habitat with greater functions and values for special-status species. These factors have been considered when applying the State CEQA Guidelines, which state that the Project would result in a significant impact on vegetation resources if it would:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species (including listed species) or on any riparian habitat or other special-status vegetation alliances identified in local or regional plans, policies, or regulations, or by DFW or USFWS. Examples of such effects are listed below.
  - Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, riparian wetlands, seasonal wetlands, etc.) through direct removal, filing, hydrological interruption, or other means.
  - Have the potential to degrade the quality of the environment, substantially reduce the habitat of a listed or sensitive plant species, threaten to eliminate a plant or plant community, reduce the number or restrict the range of a rare or endangered plant.
  - Eliminate important vegetation examples of major periods of California history.
- Conflict with any local policies or ordinances protecting biological resources, such as a conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or State habitat conservation plan.
- Facilitate a substantial increase in distribution and abundance of invasive plants in the Project area.

6.3.3 Impacts and Mitigation Measures

This section provides an evaluation of the long-term and temporary effects of the Project alternatives on special-status vegetation alliances. It includes analyses of potential effects relative to No-Action conditions in accordance with NEPA requirements and potential impacts compared to existing conditions to meet CEQA requirements. With respect to vegetation, the environmental impact issues and concerns are the following:

1. Substantially Alter Riparian Habitat and Other Sensitive Communities during Construction.
2. Substantially Alter Riparian Habitat and Other Sensitive Communities during the Operations and Maintenance Phase of the Project.
3. Facilitate Increase in Distribution and Abundance of Invasive Plants in the Project area.
4. Conflict with Provisions of Local Plans in the Project area.

Other vegetation-related issues covered in the Program Environmental Impact Statement/Report (PEIS/R) are not covered here because they are programmatic in nature and/or are not relevant to the Project area.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. However, other proposed actions under the SJRRP would be implemented, including habitat restoration, augmentation of river flows, and reintroduction of salmon. Without the Project in Reach 2B, however, these activities would not achieve the Settlement goals. The potential effects of the No-Action Alternative are described below. The analysis is a comparison to existing conditions, and no mitigation is required for No-Action.

Impact VEG-1 (No-Action Alternative): *Substantially Alter Riparian Habitat and Other Sensitive Communities during Construction.* Under the No-Action Alternative, Project construction activities that could fragment, separate or remove native wetland, riparian, and other special-status vegetation alliances from their habitat or eliminate them would not be carried out. Compared to existing conditions, there would be **no impact**.

Impact VEG-2 (No-Action Alternative): *Substantially Alter Riparian Habitat and Other Sensitive Communities during the Operations and Maintenance Phase of the Project.* Under the No-Action Alternative, Restoration Flows in Reach 2B would increase the extent and duration of inundation, raise groundwater levels, and restore flows in areas that are inundated by flood flows only periodically (every 2 to 5 years). Restoration Flows may recruit new vegetation along the wetted channel banks; however, native riparian vegetation along the channel banks downstream of the San Mateo Avenue crossing would be maintained by the relatively stable water level held by Mendota Dam. River flows would not convert special-status vegetation alliances in the Project area to other vegetation types. For example, wetland habitats supported by Mendota Pool would not be altered. Riparian habitat would mature in areas upstream of San Mateo Avenue crossing, a **beneficial** effect.

Impact VEG-3 (No-Action Alternative): ***Facilitate Increase in Distribution and Abundance of Invasive Plants in the Project Area.*** Under the No-Action Alternative, current water and land management practices that facilitate the dispersal and establishment of invasive plant species would continue. In addition, other reasonably foreseeable projects could facilitate the dispersal and establishment of invasive plants in several ways: through transporting invasive plants' propagules into the Project area; creating bare ground for them to establish; by altering hydrology in a manner that is advantageous to invasive plant species; and eliminating competing native vegetation. Future projects would be subject to environmental review; however, only projects that have a Federal nexus are required to address impacts of invasive plant species (required under Federal Executive Order 11312), and CEQA-only projects would not necessarily be required to mitigate such impacts.

Under the No-Action Alternative, existing populations of invasive plant species would continue to be introduced and spread in the Project area. Invasive plant species would be dispersed to suitable sites by Restoration Flows, flood flows, natural and agricultural drainage, and other water releases from Friant Dam, Mendota Pool, and other facilities. Specifically, invasive plant species observed in the Project area ranked Cal-IPC high (see Section 6.1.2) have been identified as having the potential to adversely affect habitats and increase substantially as a result of continued water management operations in the Project area. However, as part of the Program, PEIS/R Conservation Measure INV-1 would implement an invasive plant monitoring and management plan to control, and where possible eradicate, invasive plant infestations (SJRRP 2011b, PEIS/R Table 2-7, page 2-75). As a result, there would be a **less than significant** impact from invasive plants.

Impact VEG-4 (No-Action Alternative): ***Conflict with Provisions of Local Plans in the Project Area.*** The No-Action Alternative would not reduce the effectiveness of the Madera and Fresno counties' general plan conservation strategies, and attainment of conservation plan goals and objectives would not otherwise be prevented. However, the No-Action Alternative would not result in beneficial effects on these plans because it would not actively support attainment of goals or objectives related to enhancing or restoring biological resources along Reach 2B. Compared to existing conditions without Interim or Restoration flows, there would be **no impact**.

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

Alternative A would include construction of Project facilities including a Compact Bypass channel, a new levee system encompassing the river channel with a narrow floodplain, and the South Canal. Other key features include construction of the Mendota Pool Dike (separating the San Joaquin River and Mendota Pool), a fish barrier below Mendota Dam, and the South Canal bifurcation structure and fish passage facility, modification of the San Mateo Avenue crossing, and the removal of the San Joaquin River control structure at the Chowchilla Bifurcation Structure. Construction activity is expected to occur intermittently over an approximate 132-month timeframe.

This alternative includes passive riparian habitat restoration and farming in the floodplain. It is assumed that over time wetland communities (obligate, facultative-wet, and facultative species) would develop within the main channel and that a dense riparian

scrubland would develop along the main river channel banks. The Restoration Flows would be used to recruit new vegetation along the channel from the existing seed bank. Between the main river channel banks and the proposed levees, agricultural practices (e.g., annual crops, pasture, or floodplain-compatible permanent crops) would occur. Invasive, non-native plant species would be removed from the channel and riparian areas during or following construction, and the Project would include long-term management for invasive plant species.

Impact VEG-1 (Alternative A): *Substantially Alter Riparian Habitat and Other Sensitive Communities during Construction.* Compared to No-Action, construction of Project features under Alternative A could have substantial effects on special-status vegetation alliances. Project actions related to these effects would include the following:

- The re-grading of the floodplain.
- The operation of equipment during construction, including, excavators, dump trucks, and graders.
- The breaching/removal of existing levees.
- Modifications to existing levees.

Re-grading the floodplain would occur primarily in existing agricultural areas but some areas of riparian habitat and other sensitive communities would be affected where floodplain grading connects to the river channel because some vegetation would be removed to complete the grading. The operation of equipment during construction would potentially affect riparian habitat and other sensitive communities through clearing, grubbing, pruning, and incidental damage, such as compression of root zones and accidental impact by machinery. Breaching and removal of existing levees, which is necessary to allow overbank flows to spread onto the floodplain, would remove existing riparian vegetation along the existing levees.

Construction of Alternative A could affect the acreages of special-status vegetation alliances shown in Table 6-5. These acreages represent the worst-case scenario where all existing floodplain areas are assumed to be impacted. “Infrastructure” generally refers to area permanently converted to structures, levees or roads. “Floodplain” primarily refers to the floodplain of the San Joaquin River and the acreage impacted under this category may be disturbed up to 3 years following construction, but eventually return to natural habitat or farming. “Borrow” refers to the maximum amount of habitat that could be disturbed to take fill materials for levees. Other impacts refer to construction staging areas, temporary access roads and other construction-related disturbances. Areas temporarily disturbed during construction will be restored to their previous contours, if feasible, and then seeded with a native vegetation seed mixture to prevent soil erosion. Some areas, such as borrow areas, may not be feasible to restore previous contours, but these areas would be smoothed and seeded (see Section 2.2.4).

However, Conservation Measures RHSNC-1 and RHSNC-2 would be implemented as part of the Project to offset adverse effects of Project construction on special-status vegetation alliances. These measures would avoid and minimize loss of riparian habitat

and other sensitive natural communities during construction of the Project, and promote re-establishment of this vegetation after construction (see Table 2-8 in Chapter 2.0, "Description of Alternatives"). Conservation Measure RHSNC-1 requires biological surveys to identify, map, and quantify riparian and other sensitive communities in the Project area. Construction in riparian habitat and other sensitive communities would be avoided, to the extent practicable. Conservation Measure RHSNC-2 requires implementing the Program's Riparian Habitat Mitigation and Monitoring Plan. If losses of sensitive vegetation communities are not offset by the Program, then compensation would be provided through creating, restoring, or preserving in-kind communities. Development and implementation of the Program mitigation and monitoring plans would support this process.

Conservation Measure PLANTS-1 would also be implemented, as appropriate, to identify, avoid, and minimize temporary or permanent loss of special-status plant species found in the Project area, if any. (No special-status plant species were identified in the Project area during field surveys in 2010 and 2011). In addition, Conservation Measure INV-1 includes monitoring and controlling the spread of invasive plant species that could interfere with successful establishment and survival of native riparian plant species. This measure would enhance riparian and emergent wetland communities by controlling invasive plant species, such as red sesbania and giant reed, which can displace native riparian and wetland species (discussed below under Impact VEG-3).

Table 6-5.
Special-Status Vegetation Alliances Potentially Affected by Alternative A

Common Name	Scientific Name	Maximum Impacted Area (Acres)

Key:
Infrastructure = structures, levees, or roads
Floodplain = floodplain of the San Joaquin River (passive restoration and agricultural activities)
Borrow = maximum amount disturbed to take fill materials for levees (reseeded)
Other = construction staging areas, temporary access roads, and other construction-related disturbances (reseeded)

Avoidance, minimization, and compensation for loss of riparian habitat, other sensitive natural communities (i.e., special-status vegetation alliances), and special-status plant species would reduce the potential for adverse effects to vegetation during construction. Because these conservation measures would be implemented as part of the Project, Alternative A would not have substantial effects on existing special-status vegetation alliances.

When comparing Alternative A to existing conditions, impacts to riparian habitat and other sensitive natural communities would be similar to those discussed in the preceding paragraphs (i.e., the comparison of Alternative A to No-Action). Compared to existing conditions, impacts of Alternative A would be **less than significant** for the reasons stated above.

Impact VEG-2 (Alternative A): ***Substantially Alter Riparian Habitat and Other Sensitive Communities during the Operations and Maintenance Phase of the Project.*** Compared to the No-Action Alternative, Alternative A would result in expanding the river's floodplain and increasing the flow conveyance capacity of Reach 2B. These changes, in combination with Restoration Flows, would cause hydrologic modifications that would change the inundation regime (duration, depth, timing, or extent), scour or deposition (due to changes in streamflow velocity), or soil moisture (due to changes in

groundwater level) available for plant growth. These changes would facilitate establishment of riparian habitat and other sensitive natural communities (special-status vegetation alliances) in some areas of the floodplain, but convert some existing vegetation to other vegetation types.

In some locations within the Project area, Restoration Flows would submerge the roots, shoots and leaves of existing riparian and wetland plants for weeks or months during each growing season. The growth of mature submerged plants would be reduced, and some plant parts would be damaged (Coops et al. 1996). Sapling trees, immature shrubs and poorly established herbaceous perennials would be killed. Successive years of prolonged submergence would result in mortality of the majority of trees, shrubs, and perennial forbs and grasses that are dominant in the riparian areas subject to flooding. However, many mature riparian and wetland plants that would be submerged are resistant to flooding damage and would survive inundation lasting up to several weeks (Karrenberg et al. 2002). Mortality would be expected in riparian and wetland vegetation subjected to complete and continual submergence for several weeks every year.

The scour and deposition of sediment can damage riparian and wetland vegetation by abrasion or burial (Friedman and Auble 1999). Along Reach 2B, scour and sediment deposition may occur, as described in Chapter 14, “Surface Water Resources and Water Quality.” However, most riparian vegetation along this reach is Fremont cottonwood, black willow, and sandbar willow scrub and the dominant species of these communities (e.g., the willows) are particularly resistant to damage by scour or burial. The dominant species of emergent wetlands (e.g., cattail and tule species) also are resistant to such damage (Grace and Harrison 1986). Furthermore, scour and deposition of sediment sustains floodplain habitats and creates opportunities for plant establishment, thus sustaining the diversity of riparian and wetland vegetation. Scour and deposition of sediment would ultimately enhance floodplain habitat and increase establishment opportunities. As a result, a substantial adverse effect on riparian or wetland vegetation is not expected.

In the long term, the Project is expected to result in a net increase in riparian and emergent wetland vegetation throughout the Project area. Passive riparian habitat restoration of the San Joaquin River would improve native floodplain and in-channel habitats, which would likely benefit native species. Benefits to native species would be realized through the re-introduction of perennial base flows as well as seasonal high flows in the river, which in turn would promote the establishment of native riparian vegetation. Well-established native plant communities in the floodplain would support rich and diverse native flora, potentially including special status plant species, and could effectively prevent invasive vegetation encroachment. Alternative A would restore river-floodplain connectivity and longitudinal connectivity of riparian vegetation near the channel (without major breaks in the distribution of woody vegetation except where natural conditions prevent establishment of native trees or shrubs), enhance landscape connectivity between the river corridor and adjacent areas of ecological significance (e.g., adjacent sloughs or tributary channels with existing riparian habitat), and protect, restore, or enhance special status vegetation communities and other plant species.

Reclamation conducted a study of vegetation response to flow regimes and mechanical actions of Project alternatives using a one-dimensional flow, sediment transport, vegetation growth model called Sedimentation and River Hydraulics One Dimensional Vegetation Model (SRH-1DV). Although there are some differences in the predicted changes in vegetation by reach between the SRH-1DV vegetation modeling results and the more qualitative potential future vegetation evaluation, both predict an overall expansion of riparian vegetation in Reach 2B in response to Restoration Flows. Similarly, pilot flow studies conducted in 2000 and 2001 suggest that restoring perennial and seasonally variable flows would increase riparian plant establishment and encourage greater plant species diversity (McBain and Trush 2002).

During certain times of year in Reach 2B, Restoration Flows would increase groundwater elevations in the root zones of riparian and wetland plants and possibly submerge some, but not all, of their aboveground parts. Where this hydration or partial submergence occurs during late spring to fall, plant growth would increase because the growth of riparian and wetland plants is sensitive to water availability at these times of year (Grace and Harrison 1986, U.S. Army Corps of Engineers [Corps] 2000).

Inundation would also create conditions suitable for dispersal and establishment of riparian or wetland plants. These conditions could be created by scour and sediment deposition, water transport of plant seeds and fragments to new locations, increased water availability, and reduced competition from upland plant species (such as some nonnative grasses) that are intolerant of prolonged submergence.

When comparing Alternative A to existing conditions, impacts to riparian habitat and other sensitive natural communities would be similar to those discussed in the preceding paragraphs (i.e., the comparison of Alternative A to No-Action). According to habitat restoration estimates, Alternative A could support up to 1,420 acres of sensitive natural vegetation communities (SJRRP 2012, Attachment A). This represents more than a 3-fold increase in sensitive natural communities as compared to existing conditions. Therefore, compared to existing conditions, the Alternative A is expected to result in a **beneficial** effect.

Impact VEG-3 (Alternative A): *Facilitate Increase in Distribution and Abundance of Invasive Plants in the Project Area.* Compared to No-Action, the increased conveyance capacity, increased floodplain area, and the floodplain and channel grading of Alternative A, in combination with flood flows and Restoration Flows, could enhance dispersal of invasive plant species, and substantially increase opportunities for establishment, growth, and reproduction of invasive plant species. Invasive plants are capable of substantially affecting riparian and wetland vegetation.

Under Alternative A, invasive, non-native plant species would be removed from the Project area during the construction phase. Removal techniques may include mechanical removal, root excavation, hand pulling, mowing, disking, controlled burning, grazing, aquatic-safe herbicides, or a combination of techniques as appropriate (see Section 2.2.5). This could cause a short-term reduction in invasive plant species in the Project area.

However, invasive plant species would likely recolonize the Project area after these activities are complete.

The conveyance capacity of Reach 2B would increase under Alternative A. Flood flows and Restoration Flows could substantially increase the quantity of water flowing through Reach 2B during wet years. These hydrologic alterations could facilitate the spread of invasive plant species (e.g., red sesbania, salt cedar, giant reed-grass, and sponge plant) to new floodplain areas in Reach 2B and to downstream reaches. Flows could disperse propagules of these invasive plant species, particularly giant reed and red sesbania. Giant reed-grass, currently present at Mendota Pool and other reaches upstream, is dispersed by high flows (and machinery) that fragment plants and carry fragments downstream to new sites, where they take root and begin forming a new colony (Bossard et al. 2000). Red sesbania is currently abundant and widespread throughout Reaches 1 and 2A, but has not been observed in Reach 2B. Red sesbania produces seed pods that float for several days (Hunter and Platenkamp 2003). Sponge plant is an aquatic species distributed by water; it is present in Reach 1 but currently has a very restricted distribution in California. Therefore, these species could be dispersed to additional locations.

Floodplain and channel grading would increase the inundation area of the floodplain. In the San Joaquin Valley, invasive plant species are largely confined to sites with moderate or high levels of water availability. Therefore, by increasing water availability throughout the growing season, particularly in locations that would otherwise lack surface water (e.g., floodplain benches), Restoration Flows could aid their establishment in Reach 2B. Established plants are less sensitive than seedlings to water availability and have deeper and more extensive root systems; therefore, these plants, once established, would likely persist at additional sites. In particular, Restoration Flows may aid the establishment of red sesbania at additional locations. Because red sesbania is abundant in Reach 1 and produces floating seed that can remain dormant for at least several years, the increased availability of water during the growing season would likely allow the establishment of numerous individuals in floodplain locations where they otherwise would not have been able to germinate, grow, and survive. Furthermore, invasive plant species are more likely to become established in newly graded areas and areas subject to scour than in areas with existing cover.

Long-term management of the Project would include removal of invasive non-native plant species currently found within the reach and removal of other invasive species that are currently found in upstream reaches which eventually colonize the Project area (see Section 2.2.5). The Project would also implement Conservation Measure INV-1. Conservation Measure INV-1 requires the lead agencies to implement the Program's Invasive Vegetation Monitoring and Management Plan to control the spread and introduction of invasive plants including measures to monitor, control, and eradicate, where possible, invasive plant infestations. The Invasive Vegetation Monitoring and Management Plan includes monitoring procedures, success criteria, and adaptive management measures for controlling invasive plant species (see Section 2.2.10).

When comparing Alternative A to existing conditions, impacts would be similar to those discussed in the preceding paragraphs (i.e., the comparison of Alternative A to No-Action). For these reasons, this impact would be **less than significant**.

Impact VEG-4 (Alternative A): ***Conflict with Provisions of Local Plans in the Project Area.*** Compared to the No-Action Alternative, Alternative A would not conflict with the provisions of the Fresno and Madera counties' general plans. The Project would not substantially reduce the viability of target species, reduce habitat value or interfere with the management of conserved lands, or eliminate opportunities for conservation actions. The Project is expected to result in a long-term increase in wetland and riparian habitats and other sensitive natural communities that support special-status vegetation alliances. These consequences of implementing the Project would benefit general plans that strive to conserve, restore, and enhance these habitats and maintain the species they support. The Project would enhance opportunities to implement conservation strategies and attain conservation goals by providing hydrologic conditions necessary to restore riparian and aquatic habitats and other sensitive natural communities.

When comparing Alternative A to existing conditions, impacts would be similar to those discussed in the preceding paragraph (i.e., the comparison of Alternative A to No-Action). This would result in supporting the two general plan policies, a **beneficial** effect.

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Alternative B would include construction of Project features including a Compact Bypass channel, a new levee system with a wide, consensus-based floodplain encompassing the river channel, and the Compact Bypass Bifurcation Structure with fish passage facility. Other key features include construction of a fish passage facility at the San Joaquin River control structure at the Chowchilla Bifurcation Structure, the re-route of Drive 10 ½ (across the Compact Bypass control structure), and removal of the San Mateo Avenue crossing. Construction activity is expected to occur intermittently over an approximate 157-month timeframe.

Alternative B includes a mixture of active and passive riparian and floodplain habitat restoration and compatible agricultural activities in the floodplain. Active restoration planting would occur along the low flow channel of the river and in riparian establishment areas to establish a riparian area and seed bank, and floodplain areas would be seeded with native plants. Active revegetation activities would likely include a combination of seeding, transplanting, and pole/live stake plantings. Plantings would generally be designed as clusters of trees and shrubs with larger areas of seeded grasses and forbs. Spacing and alignment of plantings would take into account species growth patterns, potential equipment access needs for monitoring and maintenance, and desired future stand development. Passive restoration would occur in areas that rely on Restoration Flows for additional vegetation recruitment. Natural riparian recruitment (passive restoration) would promote continual habitat succession, particularly in areas where sediment is deposited or vegetation is removed by natural processes. Plantings that are wetland species or borderline wetland species would be irrigated and managed as necessary during the establishment period of 3 to 5 years. Invasive, non-native plant

species would be removed from the Project area during or following construction, and the Project would include long-term management for invasive plant species.

Impact VEG-1 (Alternative B): ***Substantially Alter Riparian Habitat and Other Sensitive Communities during Construction.*** Impacts and effects during Project construction would be similar to those analyzed under Impact VEG-1 (Alternative A), with the following exceptions. Construction of the Project under Alternative B would affect the acreages of special-status vegetation alliances shown in Table 6-6. In general, there would be fewer impacts to special-status vegetation alliances from Project infrastructure and staging areas, but more potential impacts from borrow, under Alternative B than compared to Alternative A. The amount of special-status vegetation alliances located in the Project floodplain would be higher, but much of the area impacted in the floodplain created by Alternative B would be restored through active and passive riparian and floodplain habitat restoration.

Table 6-6.
Special-Status Vegetation Alliances Potentially Affected by Alternative B

Common Name	Scientific Name	Maximum Impacted Area (Acres)			
		Infra-structure	Flood-plain	Borrow	Other
		(not future habitat)	(future habitat or agriculture)

Grassland and Herbaceous Field Alliances					
Tar plant fields	*Centromadia pungens* or other species herbaceous alliance	0.4	33.0	-	1.4
Creeping rye grass turfs	*Leymus triticoides* herbaceous alliance	-	6.1	-	-
Salt grass flats	*Distichlis spicata* herbaceous alliance	-	1.4	0.6	-

Table 6-6.
Special-Status Vegetation Alliances Potentially Affected by Alternative B

Common Name	Scientific Name	Maximum Impacted Area (Acres)			
		Infra-structure	Flood-plain	Borrow	Other
		(not future habitat)	(future habitat or agriculture)		
Marsh and Wet Meadow Alliances					
California bulrush marsh	*Schoenoplectus californicus* herbaceous alliance	0.2	18.7	3.0	0.7
Pale spike rush marsh	*Eleocharis macrostachya* herbaceous alliance	-	-	-	-
Yerba mansa meadows	*Anemopsis californica* herbaceous alliance	-	0.8	-	-
Alkali heath marsh	*Frankenia salina* alliance	-	0.2	<0.05	-
Total		***30.6***	***299.6***	***8.4***	***6.6***

Key:
Infrastructure = structures, levees, or roads
Floodplain = floodplain of the San Joaquin River (mixture of active and passive restoration and agricultural activities)
Borrow = maximum amount disturbed to take fill materials for levees (reseeded)
Other = construction staging areas, temporary access roads, and other construction-related disturbances (reseeded)

The existing native vegetation in the Project area designated to remain would be temporarily fenced with orange snow fencing (or equivalent) to prevent entry, driving, parking, or storing equipment or material within these areas during construction. This existing vegetation would be left in place or only minimally trimmed to facilitate access and work at the site. In order to maximize plant growth and planting success, existing soil and topsoil would be preserved unless the soil contains invasive non-native seed or fragmented stems and rhizomes, in which case it should not be preserved, and disturbance during construction would be minimized to the maximum practicable extent.

As described under Impact VEG-1 (Alternative A), avoidance, minimization, and compensation for loss of riparian habitat, other sensitive natural communities (i.e., special-status vegetation alliances), and special-status plant species would reduce the potential for adverse effects to vegetation during construction. Impacts of Alternative B would be **less than significant**.

Impact VEG-2 (Alternative B): *Substantially Alter Riparian Habitat and Other Sensitive Communities during the Operations and Maintenance Phase of the Project.* Project effects would be similar to those analyzed under Impact VEG-2 (Alternative A), with the following exceptions. Alternative B includes a mixture of active and passive riparian and floodplain habitat restoration and compatible agricultural activities in the floodplain in a wide, consensus-based floodplain.

Table 6-7 lists the species that are likely to be planted or seeded during active restoration. Emergent wetlands and water tolerant woody species of riparian scrub would be selected for development within the main channel, woody shrubs and trees with an herbaceous understory would be selected for development along the main river channel banks, and

bands of other habitat types (e.g., grasses) would be selected for development at higher elevations along the channel corridor. Active vegetation restoration would occur following construction and these areas would be irrigated and managed as necessary during the establishment period. Phased implementation of active vegetation restoration at strategic locations could occur concurrently with phased implementation of construction and physical infrastructure.

Table 6-7.
Potential Species for Revegetation

Common Name	Scientific Name	Vegetation Type
Riparian Shrub and Wetland Areas (0 to 2 feet above summer baseflow elevations)		
Gooding's willow	*Salix gooddingii*	tree
common buttonbrush	*Cephalanthus occidentalis*	shrub
narrowleaf willow	*Salix exigua*	shrub
redroot flatsedge	*Cyperus erythrorhizos*	annual sedge
baltic rush	*Juncus balticus*	perennial rush
dwarf barley	*Hordeum depressum*	annual grass
spike bentgrass	*Agrostis exarata*	perennial grass
meadow barley	*Hordeum brachyantherum*	perennial grass
distant phacelia	*Phacelia distans*	annual forb
seep monkeyflower	*Mimulus guttatus*	annual/perennial forb
yerba mansa	*Anemopsis californica*	perennial forb
Douglas' sagewort	*Artemisia douglasiana*	perennial forb
Dense Riparian Areas (2 to 8 feet above summer baseflow elevations)		
white alder	*Alnus rhombifolia*	tree
Oregon ash	*Fraxinus latifolia*	tree
California sycamore	*Platanus racemosa*	tree
Fremont cottonwood	*Populus fremontii*	tree
Gooding's willow	*Salix gooddingii*	tree
mule-fat	*Baccharis salicifolia*	shrub
California wildrose	*Rosa californica*	shrub
narrowleaf willow	*Salix exigua*	shrub
dwarf barley	*Hordeum depressum*	annual grass
spike bentgrass	*Agrostis exarata*	perennial grass
meadow barley	*Hordeum brachyantherum*	perennial grass
Douglas' sagewort	*Artemisia douglasiana*	perennial forb
Upland Areas (greater than 8 feet above summer baseflow elevations)		
cattle saltbush	*Atriplex polycarpa*	shrub
California wildrose	*Rosa californica*	shrub
Saltgrass	*Distichlis spicata*	perennial grass
blue wildrye	*Elymus glaucus*	perennial grass
beardless wildrye	*Leymus triticodes*	perennial grass
California goldfields	*Lasthenia californica*	annual forb
bull clover	*Trifolium fucatum*	annual forb

Plantings that are wetland species or borderline wetland species would need regular aboveground irrigation (typically April through October) during their establishment period (typically 3 to 5 years depending on rainfall conditions and the plants' growth rates and vigor). An extensive temporary aboveground irrigation system, such as aerial spray or drip irrigation, would provide water for the plants several times a week during the hot months of the year.

Maintenance and monitoring would be conducted following revegetation. Monitoring activities include monitoring of the installed plants for drought stress and overwatering, identification of competitive, invasive, non-native species for removal, identification of diseased, dead and washed-out plants, irrigation system function, and identification of trash and debris for removal. Maintenance activities would include controlling invasive plant species, mitigating animal damage, irrigation, replacement of diseased, dead, or washed-out plants, irrigation system maintenance, and removal of trash and debris.

Agricultural practices (e.g., annual crops, pasture, or floodplain-compatible permanent crops) could occur on the floodplain in previous agricultural areas outside of State-owned and public trust lands. Growers would be required to leave cover on the ground and would be required to develop and implement a Water Quality Plan, approved by the Reclamation, to meet then-existing water quality standards for coldwater fisheries beneficial in downstream areas.

When comparing Alternative B to existing conditions, impacts to riparian habitat and other sensitive natural communities would be similar to those discussed in the preceding paragraphs (i.e., the comparison of Alternative B to No-Action). According to habitat restoration estimates, Alternative B could support up to 1,970 acres of sensitive natural vegetation communities (SJRRP 2012, Attachment A). This represents more than a 5-fold increase in sensitive natural communities as compared to existing conditions. This would be a **beneficial** effect.

Impact VEG-3 (Alternative B): ***Facilitate Increase in Distribution and Abundance of Invasive Plants in the Project Area.*** Refer to Impact VEG-3 (Alternative A). Potential impacts for Alternative B would be similar to potential impacts of Alternative A with the exception that Alternative B includes a mixture of active and passive riparian and floodplain habitat restoration which may delay the establishment of invasive plant species. This impact would be **less than significant**.

Impact VEG-4 (Alternative B): ***Conflict with Provisions of Local Plans in the Project Area.*** Refer to Impact VEG-4 (Alternative A). Potential impacts for Alternative B would be the same as potential impacts of Alternative A, and would result in a **beneficial** effect compared to existing conditions.

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Alternative C would include construction of Project features including Fresno Slough Dam, a new levee system with a narrow floodplain encompassing the river channel, and the Short Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the Short Canal control structure and fish

screen, the Chowchilla Bifurcation Structure fish passage facility, modification of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 133-month timeframe.

Similar to Alternative B, Alternative C includes active riparian and floodplain habitat restoration. It is assumed that wetland communities would develop within the main channel, that a dense riparian scrubland would develop along the main river channel banks, and that bands of other habitat types (wetland, scrub, grassland, and forest) would develop at higher elevations along the floodplain corridor. The wetland, floodplain, and riparian areas would be planted following construction and then irrigated and managed as necessary during the establishment period.

Impact VEG-1 (Alternative C): *Substantially Alter Riparian Habitat and Other Sensitive Communities during Construction.* Refer to Impact VEG-1 (Alternative A). Potential impacts during Project construction for Alternative C would be similar to potential impacts of Alternative A, with the following exception. Construction of the Project would affect the acreages of special-status vegetation alliances shown in Table 6-8. As described under Impact VEG-1 (Alternative A), avoidance, minimization, and compensation for loss of riparian habitat, other sensitive natural communities (i.e., special-status vegetation alliances), and special-status plant species would reduce the potential for adverse effects to vegetation during construction. Impacts of Alternative C would be **less than significant**.

Table 6-8.
Special-Status Vegetation Alliances Potentially Affected by Alternative C

Common Name	Scientific Name	Maximum Impacted Area (Acres)			
		Infra-structure	Flood-plain	Borrow	Other
		(not future habitat)	(future habitat)	(future habitat or agriculture)

Total		***37.2***	***304.5***	***12.7***	***32.0***

Key:
Infrastructure = structures, levees, or roads
Floodplain = floodplain of the San Joaquin River (active restoration)
Borrow = maximum amount disturbed to take fill materials for levees (reseeded)
Other = construction staging areas, temporary access roads, and other construction-related disturbances (reseeded)

Impact VEG-2 (Alternative C): ***Substantially Alter Riparian Habitat and Other Sensitive Communities during the Operations and Maintenance Phase of the Project.*** Alternative C includes active riparian and floodplain habitat restoration. The wetland, floodplain, and riparian areas would be planted following construction and then irrigated and managed as necessary during the establishment period.

Several native vegetation alliances could be incorporated into the floodplain and habitat planting design. The grass-dominated vegetation alliances could be substantially larger than those that would develop under the No-Action Alternative. All of the elevated areas of the meander loops could be maintained or restored to saltgrass flats. The adjacent existing wetland areas within the loops could be preserved or enhanced by additional wetland species plantings and removal of numerous invasive plant species. The lower lying portions of the reach could be planted with the buttonwillow thicket vegetation alliance. Because of the wide floodplain and the slowly moving water, the extent of this vegetation alliance could be substantially larger than that which would develop under No-Action. The extent of black willow thicket and California mugwort brush could also increase over what might develop under the No-Action Alternative.

Additional restoration work could focus on the re-establishment of the riparian bank herbs, California bulrush marsh, Oregon ash groves, creeping rye grasslands, and Fremont cottonwood forests. Because of the fast growth and its soft and brittle wood, the cottonwood is considered to be a good source of large woody debris and organic matter within the riverine channel. The riverside levee banks would be planted with native grass species such as those in the creeping rye grassland alliance. Since creeping wild rye (*Leymus triticoides*) is a facultative wetland species that thrives in the upper parts of riparian areas, the extent of creeping rye grassland could be substantially larger than that which would develop under No-Action, a beneficial effect.

When comparing Alternative C to existing conditions, impacts to riparian habitat and other sensitive natural communities would be similar to those discussed in the preceding paragraphs (i.e., the comparison of Alternative C to No-Action). According to habitat restoration estimates, Alternative C could support up to 1,450 acres of sensitive natural vegetation communities including buttonwillow thickets, California bulrush marsh, California mugwort brush, creeping rye grass turfs, riparian banks forbes and herbs, salt grass flats, Fremont cottonwood forest, Oregon ash groves, sandbar willow thickets, and black willow thickets (SJRRP 2012, Attachment A). This represents more than a 3-fold increase in sensitive natural communities as compared to existing conditions. This would be a **beneficial** effect.

Impact VEG-3 (Alternative C): *Facilitate Increase in Distribution and Abundance of Invasive Plants in the Project Area.* Refer to Impact VEG-3 (Alternative A). Potential impacts for Alternative C would be similar to potential impacts of Alternative A with the exception that Alternative C includes active riparian and floodplain habitat restoration which may delay the establishment of invasive plant species. This impact would be **less than significant**.

Impact VEG-4 (Alternative C): *Conflict with Provisions of Local Plans in the Project Area.* Refer to Impact VEG-4 (Alternative A). Potential impacts for Alternative C would be the same as potential impacts of Alternative A. This would be a **beneficial** effect compared to existing conditions.

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Alternative D would include construction of Project features including Fresno Slough Dam, a new levee system with a wide floodplain encompassing the river channel, and the North Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the North Canal bifurcation structure and North Canal fish passage facility, removal of the San Joaquin River control structure at the Chowchilla Bifurcation Structure, removal of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 158-month timeframe.

Similar to Alternative A, Alternative D includes passive riparian habitat restoration and farming in the floodplain. It is assumed that over time wetland communities would develop within the main channel and that a dense riparian scrubland would develop along the main river channel banks. The Restoration Flows would be used to recruit new

vegetation along the channel from the existing seed bank. Between the main river channel banks and the proposed levees, agricultural practices (e.g., annual crops, pasture, or floodplain-compatible permanent crops) would occur.

Impact VEG-1 (Alternative D): ***Substantially Alter Riparian Habitat and Other Sensitive Communities during Construction.*** Refer to Impact VEG-1 (Alternative A). Potential impacts for Alternative D during Project construction would be similar to potential impacts of Alternative A with the following exception. Construction of the Project would affect the acreages of special-status vegetation alliances shown in Table 6-9. As described under Impact VEG-1 (Alternative A), avoidance, minimization, and compensation for loss of riparian habitat, other sensitive natural communities (i.e., special-status vegetation alliances), and special-status plant species would reduce the potential for adverse effects to vegetation during construction. Impacts of Alternative D would be **less than significant**.

Impact VEG-2 (Alternative D): ***Substantially Alter Riparian Habitat and Other Sensitive Communities during the Operations and Maintenance Phase of the Project.*** Refer to Impact VEG-2 (Alternative A). Similar to Alternative A, Alternative D includes passive riparian habitat restoration and farming in the floodplain. The Restoration Flows would be used to recruit new vegetation along the channel from the existing seed bank. Between the main river channel banks and the proposed levees, agricultural practices (e.g., annual crops, pasture, or floodplain-compatible permanent crops) would occur. According to habitat restoration estimates, Alternative D could support up to 2,000 acres of sensitive natural vegetation communities including buttonwillow thickets, California bulrush marsh, California mugwort brush, creeping rye grass turfs, riparian banks forbes and herbs, salt grass flats, Fremont cottonwood forest, Oregon ash groves, sandbar willow thickets, and black willow thickets (SJRRP 2012, Attachment A). This represents more than a 5-fold increase in sensitive natural communities as compared to existing conditions. This would be a **beneficial** effect.

7.0 Biological Resources - Wildlife

This chapter describes the environmental and regulatory setting for wildlife resources, as well as the environmental consequences associated with construction and operation of Project alternatives, including impacts and mitigation measures.

7.1 Environmental Setting

This section describes the wildlife resources evaluated in this Environmental Impact Statement/Report (EIS/R), including wildlife habitat types and special-status wildlife species. Fish species are discussed separately in Chapter 5.0, "Biological Resources – Fisheries."

7.1.1 Regional Setting

The Project area lies within the San Joaquin Valley, which comprises the southern portion of California's Central Valley. The San Joaquin Valley is bounded by the Sierra Nevada mountain range to the east, the Tehachapi Mountains to south, and the Coast Range to the west. With the exception of the Tulare Lake basin, the watersheds of the San Joaquin Valley drain into the San Joaquin River, which leads to the Sacramento-San Joaquin Delta and ultimately into the San Francisco Bay.

The San Joaquin River originates high in the Sierra Nevada. It rapidly descends and exits mountainous terrain in the area now occupied by Friant Dam. The river discharges to the valley floor near Gravelly Ford. Prior to agricultural development, the San Joaquin River and its main tributaries meandered across alluvial fans along the main axis of the San Joaquin Valley floor. The river distributed higher flows into a complex network of sloughs that branched off both sides of the river. It flowed through a flat, homogeneous topography and supported a limited riparian forest. The flat valley floor surrounding the riparian forest often took the form of extensive wetlands, dominated by tule marsh. Riparian forest zones were present along the margins of the primary river channel and were not very extensive (The Bay Institute 1998).

Near Mendota, the San Joaquin River merged with Fresno Slough, a wider and deeper waterway than the San Joaquin River. Fresno Slough was part of an intricate slough system that exchanged water between the Tulare Lake Basin and the San Joaquin River. Downstream from Mendota, the San Joaquin River flowed through a network of large slough channels traversing extensive riparian woodland, tule marshes, and backwater ponds until it joined with the Merced River. Downstream from this point, the floodplain was more confined and the river exhibited a highly sinuous pattern of rapid channel meander, which created a rich complex of oxbow lakes, backwater sloughs, ponds, and sand bars. In its lower sections just upstream from the Delta, the river formed low natural levees approximately 6 feet high (The Bay Institute 1998).

The San Joaquin River has changed dramatically since the early part of the 20th century. The river is now largely confined within constructed levees and bounded by agricultural and urban development, flows are regulated through dams and water diversions, and floodplain habitats have been fragmented and reduced in size and diversity (McBain and Trush 2002). As a result, wildlife habitat has substantially changed from historic conditions. The presence of Friant Dam reduces the frequency of scouring flows; consequently, the vegetation succession of riparian scrub to forest is no longer balanced by periodic loss of forest to the river because of erosion and appearance of new riparian scrub on sand and gravel bars. In addition, operation of Friant Dam has caused gradually declining flows in spring, which are periodically necessary to disperse seed of willows and cottonwoods, and establish seedlings of these riparian tree and shrub species. Drought conditions caused by diversions have also caused a loss of riparian vegetation in several reaches of the river, and urban and agricultural development has caused a gradual loss in the area available for riparian habitat (Bureau of Reclamation 1998).

Federal and State wildlife preserves have been established to conserve, protect, and enhance migratory waterfowl habitat and native ecological communities of the San Joaquin Valley. The Mendota Wildlife Area and the Alkali Sink Ecological Reserve are located approximately 4 miles to the south of the San Joaquin River at River Mile 210. The Alkali Sink Ecological Reserve is home to many sensitive species, including blunt-nosed leopard lizard, palmate-bracted bird's beak, and Hoover's woolly star. The Mendota Wildlife Area, which is hydraulically connected to Fresno Slough, is home to numerous waterfowl and wading birds.

7.1.2 Project Area

The Project area contains 20 wildlife habitat types, including one tree-dominated, three shrub-dominated, five herbaceous-dominated, three aquatic, six developed, and two non-vegetated habitat types (Figure 7-1). The habitat types were classified by vegetative cover type, which is based on vegetation structure and plant species composition. For example, shrub-dominated communities were classified as scrub due to the structure of the vegetation and then further categorized as willow or riparian scrub depending on the dominant plant species present. Generally, the habitat types were defined following the California Wildlife-Habitat Relationships System (WHR) (WHR 2010). In some instances, habitats were defined following Holland (1986) or Moise and Hendrickson (2002), depending on what best represented the habitats within the Project area. Descriptions of each habitat type are provided below.

Table 7-1 lists the habitat types and their acreage within the Project area. Approximately 90 percent of the habitat within the Project area was confirmed through on-site surveys in 2010 and 2011, when Interim Flows had begun to modify 2009 conditions; however, due to restricted access, the remaining area was assessed using aerial photograph interpretation. Additional details regarding wildlife habitats (including survey methods and additional habitat descriptions) are available in the *Mendota Pool Bypass and Reach 2B Improvements Project Technical Memorandum on Environmental Field Survey Results* (San Joaquin River Restoration Program [SJRRP] 2011a).

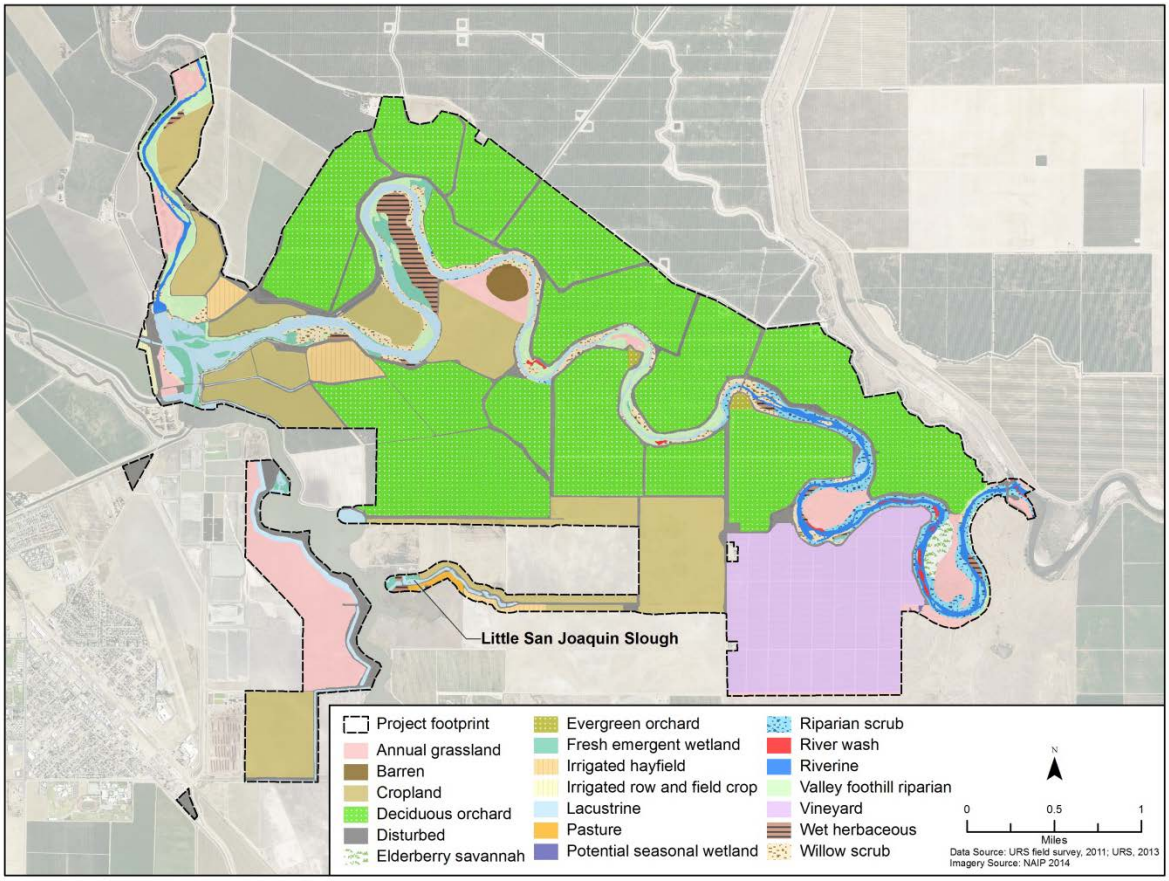

Figure 7-1.
Wildlife Habitat

Table 7-1.
Wildlife Habitat Types Mapped in the Project Area

Category	Habitat Type	Total Area (Acres)

	Riparian scrub	99
	Willow scrub	122
Herbaceous Dominated	Annual grassland	376
	Fresh emergent wetland	65
	Pasture	8
	River wash	8
	Wet herbaceous	69
Aquatic	Lacustrine	249
	Potential seasonal wetland	1
	Riverine	97

Table 7-1.
Wildlife Habitat Types Mapped in the Project Area

Category	Habitat Type	Total Area (Acres)
Developed	Cropland	896
	Irrigated hayfield	80
	Irrigated row and field crop	10
	Deciduous orchard	2,498
	Evergreen orchard	10
	Vineyard	624
Non-vegetated	Barren	25
	Disturbed	481
Total		5,894

Note: The total acreage value is calculated independently of the specific habitat acreage values; therefore, due to rounding, the value differs slightly from the sum of the habitat acres reported, which is 5,798 acres.

Tree-Dominated Habitats

Valley Foothill Riparian. As described by WHR (2010), valley foothill riparian habitat is characterized by mature riparian forest of winter deciduous trees that is generally associated with areas of floodplains and low-velocity flows with gravely or rocky soils. The typical dominant canopy species in this habitat, within the Project area, is Fremont cottonwood (*Populus fremontii*). Typical dominant subcanopy tree species include Goodding's black willow (*Salix gooddingii*), Oregon ash (*Fraxinus latifolia*), and blue elderberry (*Sambucus mexicana*). Typical understory shrub species include wild rose (*Rosa californica*), buttonbrush (*Cephalanthus occidentalis*), sandbar willow (*Salix exigua*), and, in some areas, California blackberry (*Rubus ursinus*). In the Project area, this habitat type primarily occurs in narrow bands between the river margins and croplands and therefore may be more similar to valley foothill riparian edge habitat (that is, habitat on the edge of a valley foothill riparian forest, as opposed to the interior). Accordingly, cover may be less dense than would be expected in the interior of a stand of valley foothill riparian forest, and the "forest" may appear less mature.

Shrub-Dominated Habitats

Elderberry Savannah. As described by Holland (1986), elderberry savannah habitat is characterized by a winter-deciduous shrub savannah dominated by blue elderberry (*Sambucus mexicana*) and an understory of nonnative grasses. The habitat is generally associated with alluvial soil and areas of floodplains. In natural stands this habitat typically succeeds into riparian vegetation. Typical understory species present in the Project area include tarweed (*Hemizonia* species), mustard (*Brassica* species), California wild rose (*Rosa californica*), and annual grasses.

Riparian Scrub. As described in Moise and Hendrickson (2002), riparian scrub habitat is characterized by a mix of semishrubby perennials and woody vines. In the Project area, some areas also include a layer of shrub-like trees, including tobacco tree (*Nicotiana glauca*), blue elderberry (*Sambucus mexicana*), buttonbrush (*Cephalanthus occidentalis*),

sandbar willow (*Salix exigua*), and Goodding's black willow (*Salix gooddingii*). Common understory species include California wild rose (*Rosa californica*), mugwort (*Artemisia douglasiana*), jimson weed (*Datura* species), cocklebur (*Xanthium strumarium*), nettle (*Urtica dioica*), sunflower (*Helianthus annuus*), tarweed (*Hemizonia* species), mustard (*Brassica* species) and lupin (*Lupinus* species).

Riparian scrub is distinguished from willow scrub habitat, described below, by the fact that riparian scrub is dominated by multiple species (i.e., willow and non-willow riparian species), whereas willow scrub is dominated by stands of willow species. In the Project area, much of the riparian scrub occurs along highly channelized portions of the river or areas that are subject to frequent disturbance.

Willow Scrub. As described by Moise and Hendrickson (2002), willow scrub habitat is characterized by winter deciduous, shrubby, streamside willow thickets that are generally associated with areas subject to flooding or disturbance. Typical dominant species present in the Project area include Goodding's black willow (*Salix gooddingii*) and sandbar willow (*Salix exigua*). Typical understory species include wild rose (*Rosa californica*). In the Project area, much of the willow scrub occurs along sand and gravel bars and in small patches along the banks of the San Joaquin River.

Herbaceous-Dominated Habitats

Annual Grassland. As described by WHR (2010), annual grassland habitat is characterized by open grassland dominated by annual, nonnative grass species that are generally found on flat plains or rolling hills. Typical dominant grass species include wild oats (*Avena fatua*), soft chess (*Bromus hordeaceus*), ripgut brome (*Bromus diandrus*), red brome (*Bromus madritensis*), wild barley (*Hordeum marinum*), and foxtail fescue (*Vulpia myuros*). Common forbs typically associated with this habitat include broadleaf filaree (*Erodium botrys*), redstem filaree (*Erodium cicutarium*), turkey mullein (*Eremocarpus setigerus*), true clovers (*Trifolium* species), bur clover (*Medicago minima*), and prickly popcorn flower (*Cryptantha muricata*). Tarweed (*Hemizonia* species) is common in some grassland areas.

In the Project area, annual grassland habitat occurs in several places, including on a less disturbed piece of land in the eastern portion of the Project area, south of the San Joaquin River and adjacent to elderberry savannah and riparian scrub habitat. Other areas mapped as annual grassland typically had a strong ruderal vegetation component.

Fresh Emergent Wetland. As described by WHR (2010), fresh emergent wetland habitat is characterized by erect, rooted, herbaceous, water-intense plants most commonly found on level to gently rolling topography, in depressions or at the edge of rivers or lakes in areas that are flooded frequently. Common species on the upper margins of this habitat in the Project area include yerba mansa (*Anemopsis californica*) and on more alkali sites, saltgrass. Common species on more saturated sites include common cattail (*Typha latifolia*) and tule bulrush (*Scirpus acutus* var. *occidentalis*). Fresh emergent wetland habitat, in the Project area, primarily occurs along the margins of and sometimes as small "islands" within lacustrine habitats, including portions of the San Joaquin River, Fresno

Slough, and Little San Joaquin Slough. This habitat type may blend into the wet herbaceous habitat type, described below.

Pasture. As described by WHR (2010), pasture habitat is characterized by irrigated and grazed habitat that consists of a mix of perennial grasses and legumes that provide 100 percent canopy closure planted on flat and gently rolling terrain. Species occurring in this habitat type include Bermuda grass (*Cynodon dactylon*), white melilot (*Melilotus albus*), and ryegrasses (*Lolium* species). Various annual grasses are also present. This habitat type is present south of Little San Joaquin Slough.

Riverwash. As described by Moise and Hendrickson (2002), riverwash habitat is characterized by scoured banks and bars within or adjacent to the active river channel, without significant vegetative cover. In the Project area, this habitat type is present at a few locations along the San Joaquin River.

Wet Herbaceous. Wet herbaceous habitat is characterized by annual and perennial herbaceous vegetation growing in areas with a high water table or subject to frequent flooding. These areas are typically wetter than annual grassland but not wet enough to be classified as fresh emergent wetland. Vegetation is lower-growing than in riparian scrub or valley foothill riparian habitats. Common species occurring in this habitat type include white melilot (*Melilotus albus*), Indian dogbane (*Apocynum cannabinum*), Bermuda grass (*Cynodon dactylon*), ryegrasses (*Lolium* species), tarweed (*Hemizonia* species), and cocklebur (*Xanthium strumarium*). Wet herbaceous habitat in the Project area may blend into other riparian and wetland habitats.

Aquatic Habitats

Lacustrine. As described by WHR (2010), lacustrine habitat is characterized by inland depressions or dammed riverine channels containing standing water. Due to the presence of Mendota Dam, large portions of aquatic habitat in the Project area hold water throughout the summer.

Potential Seasonal Wetland. In one portion of the Project area where access has not been granted, two features have been identified from aerial photographs as potential seasonal wetlands. The features appear to be artificially inundated and may be more appropriately described as agricultural wetlands, but since access was not available the exact character of these features remains unknown.

Riverine. As described by WHR (2010), riverine habitat is characterized by intermittent or continually running water of rivers or streams. There are three zones in this habitat type: the open water zone, submerged zone and the shore zone. Riverine habitat is present upstream of the San Mateo Avenue crossing, where water visibly flows.[1] Fresh emergent wetland habitat is mapped separately from riverine habitat, although it may be within the shore or submerged zone as defined by WHR (2010).

[1] Flows observed during the habitat assessment upstream of the San Mateo Avenue crossing surveys are due to Interim Flows.

Developed Habitats

Developed habitats in the Project area consist of agricultural lands, which dominate the area and occur in most portions of the Project area outside of the lands immediately adjacent to the San Joaquin River. Developed habitats are described by WHR (2010) as follows.

Cropland. Cropland habitat is generally characterized by a variety of annual crops, typically grown as a monoculture, which is planted in spring and harvested in summer or fall. In the Project area, an effort was made to define cropland more specifically based on the type of crop, as described below. The more general cropland habitat type was used when a more specific habitat type could not be assigned, such as where agricultural fields were temporarily fallow (this category may include temporary land fallowing/crop idling acreage) or had recently been tilled in preparation for planting a new crop at the time of the habitat assessment surveys. Fallow fields may be regularly tilled or planted with cover crops, which differentiates them from barren habitat (described below). Croplands occur in the Project area both north and south of the river.

Irrigated Hayfield. Irrigated hayfield habitat is characterized by alfalfa fields and grass hayfields where plowing may occur annually but often is less frequent. Alfalfa is typically planted as a monoculture and usually exists unplowed for approximately 3 years or more. Grass hayfields are characterized by irrigated, intensively mowed and managed grass crops with nearly 100 percent cover. In addition, occasionally "native" hayfields are irrigated to enhance their productivity. Native hayfields may include introduced grasses and forbs, but they are managed less intensively and contain a variety of naturally occurring species as well. Irrigated hayfields are found in the western portion of the Project area and near Little San Joaquin Slough.

Irrigated Row and Field Crops. Irrigated row and field crop habitat is characterized by annual or perennial green vegetable crops such as asparagus, broccoli, lettuce, cucumbers, fruits from strawberries to melons, and root vegetables such as carrots, potatoes, and beets. Cotton is also grown as an irrigated row crop. Most of these crops are grown in rows and canopy cover varies from 100 percent to crops with significant bare areas. These crops are also managed in a crop rotation system. See Section 16.1 for a discussion of specific agricultural crops and tree fruits. Irrigated row and field crops occur near the Mendota Dam area.

Deciduous Orchard. Deciduous orchard habitat is characterized by deciduous trees that produce almonds, apples, apricots, cherries, figs, nectarines, peaches, pears, pecans, pistachios, plums, pomegranates, prunes, and walnuts. Deciduous orchards typically consist of a single species of deciduous trees planted in linear, uniformly spaced rows where the crowns typically touch. Orchards in the Project area were clearly managed to reduce understory growth at the time of the habitat assessment and therefore the typical understory of low-growing grasses, legumes, and other herbaceous plants was sparse or absent from this habitat type. See Section 16.1 for a discussion of specific agricultural crops and tree fruits. Deciduous orchards are found in the Project area both north and south of the river.

Evergreen Orchard. Evergreen orchard habitat is characterized by evergreen trees that produce avocados, dates, olives, and citrus fruits. Evergreen orchard habitat typically consists of evergreen trees planted in linear, uniformly spaced rows where crowns typically do not touch. Orchards in the Project area were managed to reduce understory growth at the time of the habitat assessment surveys and therefore the typical understory composed of low-growing grasses, legumes, and other herbaceous plants was sparse or absent from this habitat type. Evergreen orchards are found in the Project area near deciduous orchards at two river bends.

Vineyard. Vineyard habitat is characterized by a single species of vines, usually supported on wood and wire trellises of boysenberries, olallieberries, raspberries, or grapes planted in rows. Typically the ground under the vines is sprayed with herbicides to prevent growth of herbaceous plants, and the ground between the rows of vines is often kept open and grasses or other herbaceous plants may be planted or allowed to grow to control erosion. A vineyard is located in the southeastern portion of the Project area.

Non-vegetated Habitats

Barren. As described by WHR (2010), barren habitat is characterized by less than 2 percent total vegetation cover by herbaceous, desert, or non-wildland species and less than 10 percent cover by tree or shrub species. This habitat is limited to non-vegetated areas that have not been significantly disturbed but instead are naturally sparsely vegetated due to hydrology or other factors. This habitat does not include areas within an active river channel (Riverwash). A section of barren habitat is found in the Project area near one of the river bends.

Disturbed. As described by Moise and Hendrickson (2002), disturbed habitat is characterized by areas where it is unlikely or impossible to find significant native vegetation, which includes permanent roads or roads at least two lanes in width, canals, levees, structures and associated landscaping, parks, golf courses, active gravel mines or other areas maintained free of vegetation by regular disturbance. This habitat is present throughout the Project area in the form of roads and structures associated with agricultural activities.

7.1.3 Special-Status Wildlife Species

Special-status wildlife species are defined here as wildlife species that meet any of the following requirements.

- Federally-listed as endangered or threatened or proposed for Federal listing under the Federal Endangered Species Act (ESA) (50 Code of Federal Regulations [CFR] 17.11 [listed animals]).
- Federal candidates for possible future listing as threatened or endangered under the ESA (73 Federal Register [FR] 75176, December 10, 2008).
- State listed as endangered or threatened, proposed for State listing, or State candidate for listing under the California Endangered Species Act (CESA) (Cal. Code Regs., tit. 14, § 670.5).

- State fully protected (Fish & G. Code, §§ 3511 [birds], 4700 [mammals], 5050 [amphibians and reptiles]).
- U.S. Fish and Wildlife Service (USFWS) Bird of Conservation Concern species (USFWS 2008).
- California Department of Fish and Wildlife (DFW) Species of Special Concern (DFW 2011).

A total of 36 special-status wildlife species were evaluated for their potential to occur in the Project area. The list of species evaluated was compiled based on a review of all California Natural Diversity Database (CNDDB) records from the Mendota Dam U.S. Geological Survey (USGS) 7.5-minute topographic quadrangle, the eight surrounding quadrangles (Jamesan, Tranquillity, Coit Ranch, Firebaugh, Poso Farm, Firebaugh NE, Bonita Ranch, and Gravelly Ford), and the area within 10 miles of Reach 2B (DFW 2009), as well as a USFWS Sacramento Field Office species list for the Mendota Dam quadrangle (USFWS 2009), and the Audubon Society Important Bird Area species list for the nearby Mendota Wildlife Area (Audubon Society 2009). Based on these sources, relevant field observations, and the presence or absence of suitable habitat, each species was designated as having high, moderate, low, or no potential to occur within the Project area. Special-status wildlife with a moderate or high potential to occur[2] are summarized in Table 7-2. Federally- and State-listed, proposed, candidate and fully protected wildlife species are listed in Table 7-3. Special-status wildlife species that lack ESA or CESA listing status or State fully protected status are listed in Table 7-4. Details regarding suitable habitat for each of these special-status wildlife species and the designations regarding the potential to occur in the Project area are presented and further explained in Mendota Pool Bypass and Reach 2B Improvements Project *Technical Memorandum on Environmental Field Survey Results* (SJRRP 2011a).

Table 7-2.
Special-Status Wildlife Species with a Moderate or High Potential to Occur

Scientific Name	Common Name	Federal Status	State Status
Federally-Listed, State-Listed, and Fully Protected Wildlife Species			
Invertebrates			
Desmocerus californicus dimorphus	valley elderberry longhorn beetle	FT	--
Reptiles			
Gambelia sila	blunt-nosed leopard lizard	FE	SE and FP
Thamnophis gigas	giant garter snake	FT	ST
Birds			
Buteo swainsoni	Swainson's hawk	MBTA	ST
Elanus leucurus	white-tailed kite	MBTA	FP
Grus canadensis tabida	greater sandhill crane	MBTA	FP
Agelaius tricolor	tricolored blackbird	BCC, MBTA	SE

[2] *Branchinecta* species are listed in Table 7-2 despite having a low potential to occur for reasons explained in Section 7.3.3, Impacts and Mitigation Measures.

Table 7-2.
Special-Status Wildlife Species with a Moderate or High Potential to Occur

Scientific Name	Common Name	Federal Status	State Status
Mammals			
Dipodomys nitratoides exilis	Fresno kangaroo rat	FE	SE
Other Special-Status Wildlife Species			
Reptiles			
Actinemys marmorata	western pond turtle	--	SSC
Anniella pulchra pulchra	silvery legless lizard	--	SSC
Masticophis flagellum ruddocki	San Joaquin coachwhip	--	SSC
Phrynosoma blainvillii	coast horned lizard	--	SSC
Birds			
Anser albifrons elgasi	greater white-fronted goose	MBTA	SSC
Asio flammeus	short-eared owl	MBTA	SSC
Athene cunicularia	burrowing owl	BCC, MBTA	SSC
Aythya americana	redhead	MBTA	SSC
Charadrius montanus	mountain plover	BCC, MBTA	SSC
Circus cyaneus	northern harrier	MBTA	SSC
Grus canadensis canadensis	lesser sandhill crane	MBTA	SSC
Lanius ludovicianus	loggerhead shrike	BCC, MBTA	SSC
Numenius americanus	long-billed curlew	BCC, MBTA	--
Pelecanus erythrorhynchos	American white pelican	MBTA	SSC
Xanthocephalus xanthocephalus	yellow-headed blackbird	MBTA	SSC
Mammals			
Eumops perotis californicus	western mastiff bat	--	SSC
Lasiurus blossevillii	western red bat	--	SSC
Taxidea taxus	American badger	--	SSC

U.S. Fish and Wildlife Service and Federal Listing Categories:
BCC = Bird of Conservation Concern
FE = Federally Listed as Endangered
FT = Federally Listed as Threatened
MBTA = Protected under the Migratory Bird Treaty Act

California Department of Fish and Wildlife State Listing Categories:
FP = Fully Protected
SE = State Listed as Endangered

Table 7-3.
Federally- and State-Listed or Fully Protected Wildlife Species

Scientific Name **Common Name**	**Federal/ State Status**	**Preferred Habitat**	**Potential to Occur in the Project area**
Invertebrates			
Branchinecta longiantenna longhorn fairy shrimp	FE/--	Found in vernal pools, particularly clear to turbid grass-bottomed pools and clear-water pools in sandstone depressions.	Low: No suitable habitat observed during habitat assessment surveys. Suitable habitat absent from Project area.
Branchinecta lynchi vernal pool fairy shrimp	FT/--	Found in vernal pools, particularly small, clear-water sandstone depression pools and grassy swale, earth slump, or basalt-flow depression pools.	Low: No suitable habitat observed during habitat assessment surveys. Suitable habitat absent from Project area.
Desmocerus californicus dimorphus valley elderberry longhorn beetle	FT/--	Elderberry shrubs with stem diameters of 2 to 8 inches. Species always found close to host plant. Larvae may remain in stems for up to 2 years.	High: Elderberry shrubs abundant in Project area. Old exit holes observed during protocol surveys.
Amphibians			
Ambystoma californiense California tiger salamander	FT/ST	Grasslands and understory of valley-foothill hardwood habitats. Require vernal pools or other seasonal water sources for breeding and mammal burrows or other underground refuges.	Low: Project area outside known current and historic range. No suitable habitat observed during habitat assessment surveys. Suitable habitat absent from Project area.
Rana draytonii California red-legged frog	FT/SSC	Pools with emergent vegetation, typically without predatory fish, and upland hibernacula, such as small mammal burrows or moist leaf litter.	Low: Assumed absent from the Project area and vicinity, based on current known distribution, presence of two invasive ranid frog species, and presence of invasive, predatory fish species.
Reptiles			
Gambelia sila blunt-nosed leopard lizard	FE/SE and FP	Sparsely vegetated alkali and desert scrub habitats, in areas of low topographic relief. Seek cover in mammal burrows, under shrubs or structures such as fence posts.	Moderate: No suitable habitat observed during habitat assessment surveys. Suitable habitat absent from Project area, with possible exception of unsurveyed land in southeast of the Project area.
Thamnophis gigas giant garter snake	FT/ST	Marshes, low-gradient streams, canals, and irrigation ditches with dense emergent vegetation, water persisting throughout the active period, open areas along water margins, and access to upland habitat for hibernation and escape from flooding.	High: Previously detected in Project area (DFW 2009). Suitable habitat observed in portions of the San Joaquin River affected by Mendota Dam, and in Fresno Slough.

Table 7-3.
Federally- and State-Listed or Fully Protected Wildlife Species

Scientific Name **Common Name**	**Federal/ State Status**	**Preferred Habitat**	**Potential to Occur in the Project area**
Birds			
Agelaius tricolor tricolored blackbird	BCC, MBTA/SE	Typically nests next to open water in freshwater marsh with extensive emergent or riparian vegetation. Breeding colonies also reported in grain fields. Forages in grasslands, wetland habitats, and some agricultural areas.	High: Observed along San Joaquin River corridor during a 19 May 2010 site visit.
Aquila chrysaetos golden eagle	MBTA, GBEPA/FP	Found in rolling hills, mountain areas, sage-juniper flats, or deserts. Forages in open areas with low vegetation. Nests on cliff faces or in large trees.	Low: No eagles or suitable eagle nesting habitat observed during habitat assessment survey. May occur during foraging or wintering but nesting not expected.
Buteo swainsoni Swainson's hawk	MBTA/ST	Nests in riparian areas, oak woodlands, and isolated and roadside trees close to grassland or agricultural foraging habitat.	High: Swainson's hawk nests previously documented in Project area (DFW 2009). Two pairs present in Project area during habitat assessment survey.
Coccyzus americanus occidentalis western yellow-billed cuckoo	FC, BCC, MBTA/SE	Large blocks of riparian habitats (particularly woodlands with willow and cottonwood) along floodplains of larger river systems. Dense understory foliage important.	Low: Project area located outside of current known range. Suitable habitat limited and not observed during habitat assessment survey. Not likely to occur due to extended absence from the region.
Elanus leucurus white-tailed kite	MBTA/FP	Prefers grasslands, oak woodlands, riparian scrub, and savannas. Forages in wetland and grassland areas.	High: Species observed in the Project area during valley elderberry longhorn beetle surveys.
Grus canadensis tabida greater sandhill crane	MBTA/FP	Nests in wet meadows and emergent marshes. Forages in wet meadows, marshes, freshwater margins, and less frequently grasslands and croplands.	High: Sandhill cranes observed flying nearby during valley elderberry longhorn beetle protocol survey –may be different subspecies. Likely an uncommon visitor during nonnesting season.
Riparia riparia bank swallow	MBTA/ST	Colonial nester primarily in riparian and other lowland habitats west of the desert. Requires vertical banks/cliffs with fine-textured/sandy soils near water to dig nest cavity.	Low: No suitable nesting habitat observed during habitat assessment survey. Suitable nesting habitat no longer present at historic Mendota Pool occurrence location.

Table 7-3.
Federally- and State-Listed or Fully Protected Wildlife Species

Scientific Name **Common Name**	**Federal/ State Status**	**Preferred Habitat**	**Potential to Occur in the Project area**
Vireo bellii pusillus Least Bell's vireo	FE/SE/ MBTA	Nests in riparian woodlands, especially willows and other shrubs, along low elevation riverine areas. Forages in riparian and adjacent uplands.	Low: No individuals were found during protocol surveys. Nearest known occurrence is San Luis Reservoir (approximately 55 miles northwest)
Mammals			
Ammospermophilus nelsoni Nelson's antelope squirrel	--/ST	Merced County south to Kings, Tulare and Kern counties, at elevations ranging from 200 to 1,200 feet. Dry, sparsely vegetated loam soils with widely scattered shrubs, forbs, and grasses in broken terrain with gullies and washes.	Low: Species not observed during habitat assessment survey, although California ground squirrels were observed. Project area is north of current range of this species.
Dipodomys nitratoides exilis Fresno kangaroo rat	FE/SE	Restricted to native grasslands in Fresno County within the San Joaquin Valley; nearly level, light, friable soils in chenopod scrub and grassland communities.	Moderate: Despite efforts to trap this species, it has not been detected at nearby sites where it was present in 1992. Kangaroo rat sign (e.g., tail drags, potential burrows) was observed in the Project area (primarily east and west loops), although 2011 trapping efforts within the Project area captured only Heermann's kangaroo rat.
Vulpes macrotis mutica San Joaquin kit fox	FE/ST	Grassland or grassy open stages with scattered shrubby vegetation; requires loose-textured sandy soils for burrowing; requires suitable prey base of small rodents.	Low: Although habitat potentially offering denning and foraging opportunities was observed during the habitat assessment survey, prior surveys in portions of the Project area have failed to confirm the presence of this species, and it is presumed extirpated in the area by USFWS (USFWS 2010).

U.S. Fish and Wildlife Service and Federal Listing Categories:
BCC = Bird of Conservation Concern
FC = Candidate for Federal Listing
FD = Federally Delisted
FE = Federally Listed as Endangered
FT = Federally Listed as Threatened
GBEPA = Protected under the Golden and Bald Eagle Protection Act
MBTA = Protected under the Migratory Bird Treaty Act

SE = State Listed as Endangered
SSC = Species of Special Concern
ST = State Listed as Threatened

Table 7-4.
Other Special-Status Wildlife Species

Scientific Name **Common Name**	**Federal/ State Status**	**Preferred Habitat**	**Potential to Occur in the Project area**
Amphibians			
Spea hammondii western spadefoot	--/SSC	Grassland and valley-foothill hardwood woodlands, vernal pools or seasonal wetlands are essential for egg laying.	Low: No suitable habitat observed during habitat assessment surveys. Suitable habitat absent from Project area.
Reptiles			
Actinemys marmorata western pond turtle	--/SSC	Ponds, marshes, rivers, streams, irrigation ditches, and vernal pools; with basking sites and suitable upland habit for egg laying.	High: Species observed in the Project area during habitat assessment survey, including likely nest.
Anniella pulchra pulchra silvery legless lizard	--/SSC	Sand dunes or sandy soil, with litter; also wooded stream edges, and occasionally desert-scrub. Bush lupine often indicates suitable conditions. Found in leaf litter, under rocks, logs, and driftwood.	High: Species known from immediately adjacent to the Project area and suitable habitat present at various locations in the Project area.
Masticophis flagellum ruddocki San Joaquin whipsnake	--/SSC	Open, dry, treeless areas, including grassland and saltbush scrub. Takes refuge in rodent burrows, under shaded vegetation, and under surface objects.	High: Recent nearby occurrences and suitable habitat present in the Project area.
Phrynosoma blainvillii coast horned lizard	--/SSC	Coastal sage, chaparral, and other brushy, shrubby vegetation habitats that provide a low shrub structure; Overwinters in small mammal burrows.	High: Recent nearby occurrences, suitable habitat and some native ant colonies present in the Project area.
Birds			
Accipiter cooperii Cooper's hawk	MBTA/WL	Typically found in patchy woodlands. Nests and forages near open water and wetland vegetation.	High: Observed along San Joaquin River corridor during habitat assessment survey.
Anser albifrons elgasi greater white-fronted goose	MBTA/SSC	Prefers moist and wet environments, including freshwater wetlands, croplands, and pastures. Breeds in Alaska.	High: Likely present during winter and migratory periods. August habitat assessment survey did not provide opportunity to observe this species.
Asio flammeus short-eared owl	MBTA/SSC	Open grasslands, prairies, dunes, irrigated fields, and wetlands. Nests on the ground in tall grass stands.	High: Observed along San Joaquin River corridor during habitat assessment survey and during valley elderberry longhorn beetle surveys.

Table 7-4.
Other Special-Status Wildlife Species

Scientific Name **Common Name**	**Federal/ State Status**	**Preferred Habitat**	**Potential to Occur in the Project area**
Athene cunicularia burrowing owl	BCC, MBTA/SSC	Open, dry, annual or perennial grasslands, deserts, and scrublands characterized by low-growing vegetation, with small mammal burrows for nesting and roosting.	Moderate: Observed flying just north of the Project area. Suitable habitat is present within the Project area, but no sign of this species was observed during wildlife habitat assessment survey.
Aythya americana redhead	MBTA/SSC	Nests near freshwater emergent wetlands and areas of deep, open water.	Moderate: Although suitable habitat is present in the Project area, this species was not observed during the habitat assessment survey.
Charadrius montanus mountain plover	BCC, MBTA/SSC	Roosts and forages in short grasslands, freshly plowed fields, and bare ground with flat topography. Prefers fallow, grazed, or burned areas and alkali flats with burrowing rodents.	Moderate: Potential wintering and foraging habitat is present in the Project area.
Circus cyaneus northern harrier	MBTA/SSC	Nests and forages in open habitats including freshwater marshes and weedy edges of rivers and streams. Also found in agricultural areas such as pastures and some croplands.	High: Observed along San Joaquin River corridor during habitat assessment survey.
Falco columbarius merlin	MBTA/WL	Occurs in coast, grasslands, savannas, woodlands, coniferous forests, wetlands, and occasionally desert habitats. Requires dense tree stands near bodies of water.	High: Observed in Project area near Fresno Slough during valley elderberry longhorn beetle protocol surveys.
Grus canadensis canadensis lesser sandhill crane	MBTA/SSC	Forages in agricultural fields, pastures, and mowed to grazed grasslands. Roosts in shallow water within wetland habitats.	Moderate: Potential wintering and foraging habitat is present in the Project area.
Lanius ludovicianus loggerhead shrike	BCC, MBTA/SSC	Breeds in shrubland or open woodlands. Requires tall shrubs/trees for hunting perches and nests. Uses riparian edges in the Central Valley.	High: Observed along San Joaquin River corridor during habitat assessment survey.
Larus californicus California gull	MBTA/WL	Preferred inland habitat includes riverine, lacustrine, and cropland habitats.	Moderate: Potential wintering and foraging habitat is present in the Project area. Observed flying over the Project area.
Numenius americanus long-billed curlew	BCC, MBTA/WL	Winters in upland herbaceous areas and croplands.	High: Observed in the Project area during valley elderberry longhorn beetle surveys. Potential wintering and foraging habitat is present in the Project area.

Table 7-4.
Other Special-Status Wildlife Species

Scientific Name **Common Name**	**Federal/ State Status**	**Preferred Habitat**	**Potential to Occur in the Project area**
Pandion haliaetus osprey	MBTA/WL	Found near large, open, fish-bearing waters. Nests and roosts on large tree, snags, and cliffs.	Moderate: Potential wintering and foraging habitat is present in the Project area.
Pelecanus erythrorhynchos American white pelican	MBTA/SSC	Forages in shallow inland waters such as marshes, canals and lake or river edges.	High: Observed at Mendota Pool during habitat assessment survey.
Phalacrocorax auritus double-crested cormorant	MBTA/WL	Found in riverine habitats within the Central Valley.	High: Observed at Mendota Pool during habitat assessment survey.
Plegadis chihi white-faced ibis (rookery site)	MBTA/WL	Forages in emergent freshwater wetlands and flooded croplands/pastures. Roosts in dense wetland vegetation.	Moderate: Observed flying over the Project area. Potential rookery and foraging habitat present in the Project area.
Xanthocephalus xanthocephalus yellow-headed blackbird	MBTA/SSC	Nests in marshes with tall emergent vegetation and areas of relatively deep water.	High: Observed along San Joaquin River corridor and Fresno Slough during valley elderberry longhorn beetle protocol surveys.
Mammals			
Eumops perotis californicus western mastiff bat	--/SSC	Roosts in crevices in cliff faces, high buildings, and tunnels; forages in arid, semi-arid habitat-coniferous and deciduous woodlands, coastal scrub, grasslands, and chaparral.	High: Although evidence of roosting habitat was not observed during the habitat assessment survey, may forage over much of the Project area.
Lasiurus blossevillii western red bat	--/SSC	Roosts primarily in trees, typically adjacent to open fields or streams, which are protected above and open below for foraging; prefers habitat edges and mosaics with trees.	High: May roost in trees in riparian habitat in the Project area, and may forage over much of the Project area.
Taxidea taxus American badger	--/SSC	Grasslands, savannas, and mountain meadows; require friable soils, and relatively open, uncultivated ground; requires suitable prey base of burrowing rodents.	Moderate: Although potentially suitable habitat is present in the Project area, no sign of this species was observed during the habitat assessment survey.

SSC = Species of Special Concern
ST = State Listed as Threatened
WL = Watch List

7.2 Regulatory Setting

7.2.1 Federal

The following subsections describe Federal laws and regulations governing the protection of wildlife resources.

Federal Endangered Species Act of 1973

The ESA (16 United States Code [USC] Sections 1531 to 1543) and subsequent amendments provide guidance for the conservation of Federally-listed species and the ecosystems on which they depend.

Prohibited Acts. Section 9 of the ESA prohibits the "take" of any fish or wildlife species listed under the ESA unless otherwise authorized by Federal regulations. The term "take" means to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct (16 USC Section 1532:19). Two processes whereby take is allowed when it is incidental to an otherwise legal activity are described in Section 7 and Section 10, respectively. Section 9 of the ESA also prohibits the unlawful removal, damage or destruction of any endangered plant under Federal jurisdiction, or where in non-Federal areas, in knowing violation of any State law.

Interagency Consultation and Biological Assessments. Section 7 of the ESA provides a means for authorizing the "take" of threatened or endangered species by Federal agencies, and applies to actions that are conducted, permitted, or funded by a Federal agency. The statute requires Federal agencies to consult with the USFWS or National Marine Fisheries Service (NMFS), as appropriate, to ensure that actions they authorize, fund, or carry out are not likely to jeopardize the continued existence of threatened or endangered species or result in the destruction or adverse modification of critical habitat for these species. If a proposed project "may affect" a listed species or destroy or modify critical habitat, the lead agency is required to prepare a biological assessment evaluating the nature and severity of the potential effect.

Habitat Conservation Plans. Section 10 of the ESA requires that non-Federal landowners obtaining an Incidental Take Permit from the USFWS for activities that might incidentally harm (or "take") endangered or threatened wildlife on their land. To obtain a permit, an applicant must develop a Habitat Conservation Plan that is designed to offset any harmful impacts the proposed activity might have on the species.

Fish and Wildlife Coordination Act

The Fish and Wildlife Coordination Act (16 USC Sections 661 to 667e et seq.) applies to any Federal project where any body of water is impounded, diverted, deepened, or otherwise modified. Project proponents are required to coordinate with USFWS and/or NMFS and the appropriate State wildlife agency.

Migratory Bird Treaty Act

The Migratory Bird Treaty Act (MBTA; USC Sections 703 to 712) makes it unlawful unless expressly authorized by permit pursuant to Federal regulations to "pursue, hunt, take, capture, kill, attempt to take, capture or kill, offer for sale, sell, offer to purchase,

purchase, deliver for shipment, ship, cause to be shipped, deliver for transportation, transport, cause to be transported, carry, cause to be carried by any means whatever, receive for shipment, transportation or carriage, or export at any time, or in any manner, any migratory bird, or any part, nest, or egg of any such bird."

This includes direct and indirect acts with the exception of harassment and habitat modification, which are not included unless they result in direct loss of birds, nests, or eggs. Most bird species occurring in California fall under the protection of the MBTA except those species that belong to the families not listed in any of the four treaties, such as wrentit (*Chamaea fasciata*), European starling (*Sturnus vulgaris*), California quail (*Callipepla californica*), ring-necked pheasant (*Phasianus colchicus*), and chukar (*Alectoris chukar*), among others less common in California. The MBTA is administered by USFWS Division of Migratory Bird Management.

The Migratory Bird Treaty Reform Act (Division E, Title I, Section 143 of the Consolidated Appropriations Act, 2005, Public Law 108–447) amends the MBTA (16 USC Sections 703 to 712) such that nonnative birds or birds that have been introduced by humans to the United States or its territories are excluded from protection under the Act. It defines a native migratory bird as a species present in the United States and its territories as a result of natural biological or ecological processes. This list excluded two additional species commonly observed in the United States, the rock dove (*Columba livia*) and domestic goose (*Anser domesticus*).

Bald and Golden Eagle Protection Act

The Bald and Golden Eagle Protection Act (16 USC 668-668d, 54 Stat. 250) as amended, provides protection for the bald eagle (*Haliaeetus leucocephalus*) and golden eagle (*Aquila chrysaetos*) by prohibiting the taking, possession, and commerce of such birds, their nests, eggs, or feathers unless expressly authorized by permit pursuant to Federal regulations.

Protection of Migratory Bird Populations (Executive Order 13186)

Executive Order 13186 directs each Federal agency taking actions that have or may have adverse impacts on migratory bird populations to work with the USFWS to develop a memorandum of understanding that would promote the conservation of migratory bird populations. This includes avoiding and minimizing adverse impacts on migratory bird resources when conducting agency actions, restoring and enhancing migratory bird habitats, and preventing or abating the pollution or detrimental alteration of the environment for the benefit of migratory birds.

7.2.2 State of California

The following subsections describe State laws and regulations governing the protection of biological resources.

California Endangered Species Act

The CESA (Fish & G. Code, §§ 2050 to 2085) establishes the State policy to conserve, protect, restore, and enhance threatened or endangered species and their habitats by protecting "all native species of fishes, amphibians, reptiles, birds, mammals,

invertebrates, and plants, and their habitats, threatened with extinction and those experiencing a significant decline which, if not halted, would lead to a threatened or endangered designation." Animal species are listed by DFW as threatened or endangered, and plants are listed as rare, threatened, or endangered. However, only those plant species listed as threatened or endangered receive protection under the CESA.

The CESA mandates that State agencies do not approve a project that would jeopardize the continued existence of these species if reasonable and prudent alternatives are available that would avoid a jeopardy finding. There are no State agency consultation procedures under the CESA. For projects that would affect a species that is Federally- and State-listed, compliance with ESA satisfies the CESA if DFW determines that the Federal incidental take authorization is consistent with the CESA under Section 2080.1. For projects that would result in take of a species that is State listed only, the project sponsor must apply for a take permit, in accordance with Section 2081, subdivision (b).

Fully Protected Species

Four sections of the Fish and Game Code (§§ 3511, 4700, 5050, and 5515) list 37 fully protected species. These sections prohibit take or possession "at any time" of the species listed, with few exceptions, and state that "no provision of this code or any other law will be construed to authorize the issuance of permits or licenses to 'take' the species," and that no previously issued permits or licenses for take of the species "shall have any force or effect" for authorizing take or possession.

Bird Nesting Protections

Bird nesting protections in the Fish and Game Code (§§ 3503, 3503.5, 3511, and 3513) include the following.

- Section 3503 prohibits the take, possession, or needless destruction of the nest or eggs of any bird.
- Section 3503.5 prohibits the take, possession, or needless destruction of any nests, eggs, or birds in the orders Falconiformes (new world vultures, hawks, eagles, ospreys, and falcons, among others), or Strigiformes (owls).
- Section 3511 prohibits the take or possession of fully protected birds.
- Section 3513 prohibits the take or possession of any migratory nongame bird, or part thereof, as designated in the MBTA.

To avoid violation of the take provisions, it is generally required that project-related disturbance at active nesting territories be reduced or eliminated during the nesting cycle.

Lake and Streambed Alteration

Fish and Game Code section 1600 et seq. requires DFW to be notified before any project activity that would do any of the following.

- Substantially divert or obstruct the natural flow of any river, stream, or lake.
- Substantially change or use any material from the bed, channel, or bank of any river, stream, or lake.

- Deposit or dispose of debris, waste, or other material containing crumbled, flaked, or ground pavement where it may pass into any river, stream, or lake.

The Lake and Streambed Alteration notification requirement applies to work undertaken in or near a river, stream, or lake that flows at least intermittently through a bed or channel. This includes ephemeral streams, desert washes, and watercourses with subsurface flow. It may also apply to work undertaken in the floodplain. Preliminary notification and project review generally occur during the environmental process.

When an existing fish or wildlife resource may be substantially adversely affected, DFW proposes reasonable modifications to the project to protect the resources. These modifications, or conditions, are formalized in a Lake or Streambed Alteration Agreement that becomes part of the plans, specifications, and bid documents for the project.

Natural Communities Conservation Planning Act

This act was enacted to encourage broad-based planning to provide for effective protection and conservation of the State's wildlife resources while continuing to allow appropriate development and growth (Fish & G. Code, §§ 2800 to 2835). Natural Community Conservation Plans may be implemented, which identify measures necessary to conserve and manage natural biological diversity within the planning area, while allowing compatible and appropriate economic development, growth, and other human uses.

7.2.3 Regional and Local

The following subsections describe the regional and local regulations governing the protection of wildlife resources.

San Joaquin River Management Program

The San Joaquin River Management Program was authorized by Assembly Bill (AB) 3603 and signed by the governor on September 18, 1990. Specific issues addressed by San Joaquin River Management Program include flood protection, water supply, water quality, recreation, fisheries, and wildlife. San Joaquin River Management Program produced a report in 1995, outlining recommendations in the form of projects, studies, and acquisitions.

Central Valley Joint Venture

The Central Valley Joint Venture is a self-directed coalition consisting of 20 Federal and State agencies and private conservation organizations. This partnership directs its efforts toward the common goal of providing for the habitat needs of migrating and resident birds in the Central Valley of California. The Central Valley Joint Venture was established in 1988 as a regional partnership focused on the conservation of waterfowl and wetlands under the North American Waterfowl Management Plan. It has since broadened its focus to the conservation of habitats for other birds, consistent with major national and international bird conservation plans and the North American Bird Conservation Initiative. The Central Valley Joint Venture Implementation Plan (2006)

has identified specific goals and objectives for conservation activities for waterfowl, shorebirds, waterbirds, and riparian songbirds.

Fresno County General Plan

The Open Space and Conservation Element of the Fresno County General Plan (Fresno County 2000) outlines several policies designed to protect wildlife and their habitat. These policies include the following.

- Policies OS-D.4 through OS-D.6 require the protection of wetlands, riparian areas, and the adjacent upland habitats.
- Policies OS-E.1 through OS-E.18 require the protection of wildlife habitats and movement and migration corridors through construction buffers, management practices, conservation plans, pest control, pesticide use monitoring, and conservation.

Madera County General Plan

The Madera County General Plan Policy Document (Madera County 1995) outlines several policies designed to protect wildlife and their habitat in the Agricultural and Natural Resources section of the plan. These policies include the following.

- Policies 5.D.4 through 5.D.6 require the protection of wetlands, riparian areas, and the adjacent upland habitats.
- Policies 5.E.1through 5.E.10 require the identification and protection of wildlife habitats, including habitat for rare, threatened, endangered, and indigenous species, through management practices, monitoring of pesticide use, ground squirrel control, environmental review processes, and conservation.

7.3 Environmental Consequences and Mitigation Measures

7.3.1 Impact Assessment Methodology

This section describes the methods used to evaluate potential impacts to wildlife resources. First described are the background reviews and field surveys which were used or conducted to identify wildlife resources that may be impacted by the Project. The specific methods that were used to determine Project impacts are then described.

Identification of Wildlife Resources in the Project Area

Wildlife resources potentially occurring in the Project area were identified through queries of existing databases and agency information and by field surveys. Three primary databases were reviewed to obtain special-status wildlife species occurrence data from within the Project area and vicinity: CNDDB (DFW 2009), USFWS Sacramento Field Office Species List (USFWS 2009), and Audubon Society Important Bird Area species list for the Mendota Wildlife Area (Audubon Society 2009). These and other sources of information used are described in detail in the Mendota Pool Bypass and Reach 2B Improvements Project *Technical Memorandum on Environmental Survey Results* (SJRRP 2011a, Section 3).

Wildlife habitat assessment surveys were conducted to identify and map habitats present within the Project area and to record direct and indirect wildlife observations. These surveys were conducted in the Project area from August 23 through 27, 2010. With the exception of developed agricultural areas, surveys were conducted on foot throughout portions of the Project area where access to private- or publicly-owned property had been granted, primarily parcels located south of the San Joaquin River. In developed agricultural areas and where foot surveys were not possible, either because vegetation was too dense or access was not granted, "windshield surveys" were done largely by a biologist observing from a car. For these windshield surveys, the field team used binoculars and a spotting scope to observe habitat features and wildlife from the public road. Approximately 90 percent of the habitat within the Project area was confirmed through on-site surveys.

Supplemental focused surveys were conducted for birds, valley elderberry longhorn beetle, and small mammals. A post-breeding season bird survey was conducted on August 26, 2010, and an early breeding season bird survey was conducted on March 3, 2011. Additional surveys were conducted in 2014. Protocol level surveys were conducted for valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*) March 1, 2011 through March 4, 2011 and March 8, 2011 through March 9, 2011 according to the protocol established by USFWS in Conservation Guidelines for the Valley Elderberry Longhorn Beetle (USFWS 1999) in applicable areas with authorized site access. While these surveys provide an estimate for comparing alternatives, the area will need to be resurveyed for valley elderberry longhorn beetle as part of the permitting process. Small mammal trapping, focused on detection of Fresno kangaroo rat (*Dipodomys nitratoides exilis*), was conducted during summer 2011 in applicable areas with authorized site access.

Habitat data collected during the habitat assessment surveys were used in combination with existing data and aerial photograph interpretation to map wildlife habitats throughout the Project area. The habitat types were largely defined according to the California Wildlife-Habitat Relationships System (WHR 2010); however, certain habitats were also defined using Holland (1986) and Moise and Hendrickson (2002), where appropriate. Additional description of field surveys and habitat mapping are presented in the Mendota Pool Bypass and Reach 2B Improvements Project *Technical Memorandum on Environmental Survey Results* (SJRRP 2011a, Section 3).

The assessment of wildlife resources would be amended when access to the entire Project area is granted, or following additional surveys, should they be implemented before land acquisition. Surveys may determine that habitat for special-status species is not present in the Project area. For certain target species, protocol-level surveys may be conducted; if target species are not encountered, a species may be considered absent with agency approval. In these situations, impacts to those wildlife resources would not exist and implementation of the conservation measures for the protected species would no longer be required.

Impact Evaluation Methodology

The evaluation of potential impacts to wildlife resources used in the alternatives analysis is both quantitative and qualitative in nature. Wherever possible, quantitative analyses were used to determine the acres of potential habitat lost or altered for each special-status wildlife species as a result of the Project. Included in this analysis was direct habitat loss that would occur as a result of Project construction activities including grading, levee construction, and the placement of fill, and indirect habitat loss that would result from new hydrologic patterns that may over time alter existing vegetation and habitats.

To calculate these impacts, geographic information system data were used to create a master habitat layer, based on the wildlife habitat mapping effort described above, to estimate the location and area of potential habitat present within the Project area under existing conditions. Most species-specific impact calculations were generated by intersecting Project impact layers with the appropriate habitat types for each species. This methodology was used to generate impact numbers for each species for each alternative.

Species that were not analyzed using this methodology included valley elderberry longhorn beetle, blunt-nosed leopard lizard, giant garter snake, western pond turtle, and Fresno kangaroo rat. Impacts due to habitat loss for valley elderberry longhorn beetle were estimated based on a count of elderberry shrubs affected by each alternative. The analysis of blunt-nosed leopard lizard and Fresno kangaroo rat habitat loss included the results of species-specific habitat surveys. Habitat loss for giant garter snake and western pond turtle were assessed using the distribution of their aquatic habitats and an associated 200-foot upland buffer.

Potential impacts were also evaluated qualitatively for individual special-status wildlife species and potential wildlife habitat. Examples of impacts that were evaluated qualitatively include noise, motion and startle, dust, and changes in hydrology.

7.3.2 Significance Criteria

For impacts to wildlife resources, the thresholds of significance are based on Appendix G of the State California Environmental Quality Act (CEQA) Guidelines. Under National Environmental Policy Act (NEPA) Council on Environmental Quality (CEQ) Regulations, effects to wildlife resources were evaluated in terms of their context and intensity. The Project would result in a significant impact on wildlife resources if it would do any of the following.

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by DFW or USFWS.
- Interfere substantially with the movement of any native resident or migratory wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites.
- Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance.

- Conflict with the provisions of an adopted habitat conservation plan, Natural Communities Conservation Plan, or other approved State, regional or local habitat conservation plans.

7.3.3 Impacts and Mitigation Measures

This section provides a project-level evaluation of direct and indirect effects of the Project Alternatives on wildlife resources. It includes analyses of potential effects relative to No-Action conditions in accordance with NEPA and potential impacts compared to existing conditions to meet CEQA requirements. The analysis is organized by Project alternative with specific impact topics numbered sequentially under each alternative. With respect to wildlife, the environmental impact issues and concerns are:

1. Project Effects on Special-Status Invertebrate Species.
2. Project Effects on Special-Status Reptile Species.
3. Project Effects on Special-Status Bird Species.
4. Project Effects on Special-Status Mammal Species.
5. Project Effects on Wildlife Movement Corridors.
6. Long-term Habitat Improvement in Reach 2B.

Other wildlife-related issues covered in the Program Environmental Impact Statement/Report (PEIS/R) (SJRRP 2011b) are not covered here because they are programmatic in nature and/or are not relevant to the Project area.

Issues Eliminated from Further Analysis

Recovery Areas and Designated Critical Habitat. Recovery plans are non-regulatory documents developed by the USFWS to provide guidance for the recovery of threatened or endangered species. Recovery plans typically identify recovery or core areas that are important to the survival and recovery of a species. Critical habitat is a term defined and used in the ESA that refers to a specific geographic area that contains features essential for the conservation of a threatened or endangered species and that may require special management and protection.

San Joaquin Kit Fox Recovery Area. The *Recovery Plan for the Upland Species of the San Joaquin Valley, California* (USFWS 1998) identifies recovery areas for the San Joaquin kit fox. These areas are mapped and named in the *San Joaquin Kit Fox (Vulpes macrotis mutica) 5-Year Review: Summary and Evaluation* (USFWS 2010). The Project area overlaps with Satellite Area 4: Western Madera County. Although the 5-Year Review states that the species is presumed to be extirpated from this area (locally extinct) (USFWS 2010), USFWS has indicated in Project-related correspondence that kit fox occur on, or directly adjacent to the Alkali Sink Ecological Reserve located approximately 2 miles south of the Project area (Raabe, pers. comm. 2015). Project surveys have failed to confirm the presence of this species in Project area and vicinity and Project activities are not expected to have any adverse impact to San Joaquin kit fox recovery areas. Therefore, conflicts with this recovery plan are not further addressed in this document.

Vernal Pool Recovery Area. The *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (USFWS 2005) identifies 16 vernal pool regions that contain 41 core areas, which are considered critical to the preservation and recovery of one or more vernal pool species addressed by the plan. The Project area overlaps with the San Joaquin Valley vernal pool region but does not overlap with any of the core areas. Project activities are not expected to have any impact to core vernal pool recovery areas; and therefore, this issue is not further addressed in this document.

Fresno Kangaroo Rat Critical Habitat. Critical habitat for the Fresno kangaroo rat was designated on January 30, 1985 (50 CFR 4222–4226). This critical habitat unit does not overlap with the Project area but is located less than 2 miles south. Project activities are not expected to have any impact to Fresno kangaroo rat critical habitat; and therefore, this issue is not further addressed in this document.

Habitat Conservation Plans. There are no adopted habitat conservation plans, Natural Communities Conservation Plan, or other approved State, regional, or local habitat conservation plans in the Project area. Therefore, Project activities would not conflict with any such plans and this issue is not further addressed in this chapter.

Other Local and Regional Plans. The Fresno County General Plan and the Madera County General Plan are described under Regulatory Setting in Section 7.2.3, Regional and Local. The policies identified in these plans to protect biological resources are consistent with requirements of other State and Federal regulations. Project activities would not conflict with these policies; therefore, local and regional plans are not further addressed in Section 7.3, Environmental Consequences.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. However, other proposed actions under the SJRRP would be implemented, including habitat restoration, augmentation of river flows (including Restoration Flows in Reach 2B up to the existing capacity of the reach, and reintroduction of salmon. The augmentation of flows would allow riparian vegetation to naturally re-establish on river banks, especially upstream of San Mateo Avenue crossing. Without the Project in Reach 2B, however, the proposed actions in other reaches would not achieve the Settlement goals. This section describes the impacts of the No-Action Alternative. The analysis is a comparison to existing conditions, as described in Section 7.1, Environmental Setting. No mitigation is required for No-Action.

Impact WILD-1 (No-Action Alternative): *Project Effects on Special-Status Invertebrate Species.* Under the No-Action Alternative, the Project would not be implemented and there would be no construction activities in the Project area. The continuation of Restoration Flows would allow riparian vegetation to establish along previously bare banks of the San Joaquin River. This would be a potentially beneficial effect on valley elderberry longhorn beetles, as increases in riparian vegetation would likely increase the number of elderberry shrubs, the beetle's host plant. As a result, there would be a **beneficial** effect on special-status invertebrate species.

Impact WILD-2 (No-Action Alternative): *Project Effects on Special-Status Reptile Species.* Under the No-Action Alternative, the Project would not be implemented and there would be no construction activities in the Project area.

Currently, in the summer, the San Joaquin River arm of Mendota Pool extends to San Mateo Avenue, providing approximately 7 linear miles of slackwater habitat. Current management activities include drawing down Mendota Pool periodically (approximately every 2 years) during winter months for dam inspections and routing a portion of spring and early summer flood flows through Reach 2B. Although both of these activities could temporarily reduce prey base or habitat suitability for giant garter snake or western pond turtle, the margins of Mendota Pool areas near Mendota Dam and along the San Joaquin River arm are otherwise largely suitable for giant garter snake basking and foraging during most of their active period. Restoration Flows associated with the No-Action Alternative would provide flow along Reach 2B in summer months (approximately 45 cubic feet per second [cfs]) for all water year types except for critical years. This flow regime is not very different from flow through Reach 2B in recent years under Interim Flows. With the No-Action Alternative flows through Reach 2B would be limited by the existing channel capacity (additional flow would be routed through the Chowchilla Bypass), and would therefore be similar to Interim Flows.

Although changes in flow that affect water temperature and velocity in Reach 2B, particularly between Mendota Dam and San Mateo Avenue, could affect habitat suitability for giant garter snakes and western pond turtles and their prey along the river channel, the change from Interim Flows to Restoration Flows would be relatively small. These changes are not expected to affect the other special-status reptile species (blunt-nosed leopard lizard, silvery legless lizard, San Joaquin coachwhip, and coast horned lizard). The Program would implement Conservation Measure GGS-2, which includes restoration of giant garter snake habitat temporarily affected and compensation for giant garter snake habitat permanently affected (SJRRP 2011b, PEIS/R Table 2-7, page 2-65). In conclusion, there would be a **less than significant** impact to special-status reptiles.

Impact WILD-3 (No-Action Alternative): *Project Effects on Special-Status Bird Species.* Under the No-Action Alternative, the Project would not be implemented and there would be no construction activities in the Project area. The continuation of Restoration Flows would allow riparian vegetation to establish along previously bare banks of the San Joaquin River. This would provide greater foraging and nesting habitat for Swainson's hawks, white-tailed kites, and short-eared owls. No special-status birds are expected to be adversely affected. As a result, there would be a **beneficial** effect on special-status birds.

Impact WILD-4 (No-Action Alternative): *Project Effects on Special-Status Mammal Species.* Under the No-Action Alternative, the Project would not be implemented and there would be no construction activities in the Project area. The continuation of Restoration Flows would allow riparian vegetation to establish along previously bare banks of the San Joaquin River. This would provide greater foraging and roosting habitat for western red bats and more foraging habitat for western mastiff bats. There would be

no adverse effects to American badgers. As a result, there would be a **beneficial** effect on special-status mammals.

Impact WILD-5 (No-Action Alternative): *Project Effects on Wildlife Movement Corridors.* Under the No-Action Alternative, the Project would not be implemented and there would be no construction activities in the Project area. The continuation of Restoration Flows would allow riparian vegetation to establish along previously bare banks of the San Joaquin River. This would provide cover and forage for animals moving along the river course. It would also provide more habitat for migratory bird species that may use the area as a stopping point for seasonal migrations. As a result, there would be a **beneficial** effect on wildlife movement.

Impact WILD-6 (No-Action Alternative): *Long-term Habitat Improvement in Reach 2B.* Under the No-Action Alternative, Restoration Flows would allow riparian vegetation to establish along previously bare banks of the San Joaquin River. This would provide for long-term opportunities for habitat improvement in Reach 2B. As a result, there would be a **beneficial** effect on wildlife habitat.

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

Alternative A would include construction of Project facilities including a Compact Bypass channel, a new levee system with a narrow floodplain encompassing the river channel, and the South Canal. Other key features include construction of the Mendota Pool Dike (separating the San Joaquin River and Mendota Pool), a fish barrier below Mendota Dam, the South Canal bifurcation structure and fish passage facility, modification of the San Mateo Avenue crossing, and the removal of the San Joaquin River control structure of the Chowchilla Bifurcation Structure. Construction activity is expected to occur intermittently over an approximate 132-month timeframe.

This alternative includes passive riparian habitat restoration and agricultural practices in the floodplain. It is assumed that over time wetland communities and a dense riparian scrubland would develop along the main channel and river banks, respectively. The Restoration Flows would be used to recruit new vegetation along the channel from the existing seed bank. Between the main river channel banks and the proposed levees, agricultural practices (e.g., annual crops, pasture, or floodplain-compatible permanent crops) would occur.

Table 7-5 summarizes potential habitat impacts by acreage for all vertebrate species with the potential to occur in the Project area. These acreages represent the worst-case scenario where all existing floodplain areas are assumed to be impacted. “Floodplain” primarily refers to the floodplain of the San Joaquin River and the acreage impacted under this category may be disturbed up to 3 years following construction, but is expected to eventually return to habitat. “Infrastructure” generally refers to area permanently converted to structures, levees, or roads. The borrow acreages refer to the maximum amount of habitat for each species that could be disturbed to take fill materials for levees. “Other” refers to construction staging areas, temporary access roads and other construction-related disturbances. Areas temporarily disturbed during construction would be restored to their previous contours, if feasible, and then seeded with a native

vegetation seed mixture to prevent soil erosion. Some areas, such as borrow areas, may not be feasible to restore previous contours, but these areas would be smoothed and seeded (see Section 2.2.4).

Table 7-5.
Species Habitat Potentially Affected by Alternative A

Scientific Name	Common Name	Habitat Type	Maximum Impacted Area (acres)			
			Floodplain (future habitat or agriculture)	Infrastructure (not future habitat)	Borrow (future habitat or agriculture)	Other (future habitat or agriculture)
Reptiles						
Actinemys marmorata	western pond turtle	Upland	165	21	45	11

Taxidea taxus	American badger	Habitat	139	27	200	3

Notes:
Floodplain = floodplain of the San Joaquin River (passive restoration and agricultural activities)
Infrastructure = structures, levees, or roads
Borrow = maximum amount disturbed to take fill materials for levees (reseeded)
Other = construction staging areas, temporary access roads, and other construction-related disturbances (reseeded)

Impact WILD-1 (Alternative A): ***Project Effects on Special-Status Invertebrate Species.*** Compared to the No-Action Alternative, Alternative A could affect special-status invertebrate species, including valley elderberry longhorn beetle, due to construction-related activities and habitat modifications. Construction-related activities (including construction vehicle traffic, the temporary use of land for staging and access areas, noise, light, and vibration from construction activities, and other site-preparation activities such as grubbing, grading, tree removal, excavation, and driving off-road) in

suitable habitat for valley elderberry longhorn beetle could result in mortality, injury, or harassment of adults, eggs, and juveniles of special-status invertebrates.

Elderberry shrubs were mapped at a number of locations within the Alternative A footprint in the riparian corridor along the river channel and in elderberry savannah habitat (SJRRP 2011a). Levee construction, removal, and protection; floodplain grading; and the placement of other Project infrastructure (e.g., South Canal bifurcation structure) would result in long-term habitat conversion or modification, including damage or removal of valley elderberry host plants and modifications to riparian scrub and elderberry savannah habitats that may support the species. The majority of shrubs that are potentially affected are in future floodplain areas (i.e., up to 479 shrubs). These areas would be allowed to return to natural habitats after Project construction is complete, which would provide suitable habitat for elderberry shrubs after construction is complete, especially along the main river channel banks where many of the elderberry shrubs occur now. A smaller number of shrubs are in habitats that would be converted to Project infrastructure or levees (51 shrubs in riparian areas and 9 shrubs in non-riparian areas). Conservation Measures VELB-1 and VELB-2 include pre-construction surveys for elderberry shrubs and beetle exit holes, avoidance of elderberry shrubs found in the Project area, and compensatory mitigation for shrubs unavoidable during construction (Table 2-8).

Long-term effects of Alternative A include passive riparian habitat restoration in the floodplain. The continuation of Restoration Flows in the expanded floodplain would allow riparian vegetation to establish along previously bare banks of the San Joaquin River. This could have a beneficial effect on valley elderberry longhorn beetles, as increases in riparian vegetation would likely increase the number of elderberry shrubs, the beetle's host plant.

When comparing Alternative A to existing conditions, impacts to special-status invertebrate species would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). Because implementation of Project conservation measures will compensate for potential impacts, and because the completed Project would provide habitat for elderberry shrubs, Project impacts are considered **less than significant**.

Impact WILD-2 (Alternative A): ***Project Effects on Special-Status Reptile Species.*** Compared to the No-Action Alternative, Alternative A could affect special-status reptile species (i.e., blunt-nosed leopard lizard, giant garter snake, western pond turtle, silvery legless lizard, San Joaquin coachwhip, and coast horned lizard) due to activities such as vehicle traffic, the temporary use of land for staging and access areas, noise, light, vibration, and other construction-related activities (e.g., grubbing, grading, tree removal, excavation, and driving off-road) that could alter reptile habitat and directly affect special-status reptile species. These direct effects on special-status reptiles could include mortality, injury, or harassment of adults, eggs, or juveniles as a result of construction activities in suitable habitat. Construction may also result in the destruction or degradation of habitat and the loss of nesting areas, burrows, or other refugia. Mortality, injury, or harassment may also occur if these species become trapped in open, excavated

areas. Construction activities could result in temporary shifts in foraging patterns or territories and increased predation as a result of increased noise, light, infrastructure, and ground vibrations where suitable habitat is present.

Indirect effects on reptiles may include the inadvertent introduction of non-native invasive (noxious) weeds, which can reduce habitat suitability (see Chapter 6.0, "Biological Resources – Vegetation"). However, Conservation Measure INV-1 includes measures to monitor, control, and where possible eradicate invasive plant infestations during construction activities (see Table 2-8). Soil compaction, cutting, and the placement of fill in suitable habitat may indirectly affect special-status reptiles by temporarily prohibiting burrowing, or by changing the frequency of vegetative cover. Construction activities may attract opportunistic predators (e.g., ravens, feral cats, and raccoons) that may feed on special-status reptiles.

Direct effects include the conversion of one habitat type to another or to Project infrastructure. This could result in the loss of individual special-status reptiles and their habitats within the limits of disturbance. However, much of the affected habitat within the floodplain would be allowed to return to natural habitat following Project construction disturbance, and these areas would continue to provide suitable habitat for special-status reptiles (Table 7-5). Some areas with habitat for special-status reptiles would be temporarily affected during construction for construction staging or construction access. Borrow areas that provide suitable habitat for special-status reptiles could be temporarily affected. Project infrastructure would result in a small amount of loss or modification of wetland (e.g., Mendota Pool Dike) and upland habitats that may support special-status reptile species.

Implementation of Alternative A would directly affect a small amount of habitat identified as potentially suitable for blunt-nosed leopard lizard (Table 7-5). A small portion of the area affected would become natural habitat again upon Project completion, and a larger portion would be converted to Project infrastructure or levees. Construction could result in destruction of rodent burrows used by lizards for shelter. DFW lists the blunt-nosed leopard lizard as a fully-protected species. Direct take (killing or injuring) of individual lizards is prohibited. To comply with this level of protection, Conservation Measures BNLL-1 includes focused site visits and habitat assessment in potentially suitable habitat, and if necessary, protocol-level surveys, in coordination with USFWS and DFW (Table 2-8). If blunt-nosed leopard lizard were detected, measures to avoid direct take would be implemented before ground disturbing activities. Conservation Measure BNLL-2 requires that compensation for impacts to habitat for the species would be determined in coordination with USFWS and DFW. These conservation measures are designed to avoid any direct take of blunt-nosed leopard lizards.

The primary habitat of one of 13 remnant populations of giant garter snake is Mendota Wildlife Area, roughly 3 miles south of the Project area and hydraulically connected to Mendota Pool via Fresno Slough (SJRRP 2011a). Implementation of Alternative A would directly affect open water, upland, and emergent wetland habitat potentially used by giant garter snake (Table 7-5). Most of the habitat affected would be left to passively return to natural habitat upon Project completion. Some of the habitat would be temporarily

affected by construction staging or access, and some of the habitat would be converted to Project infrastructure and levees. Although the exact location of the up to 350 acres of borrow has not been identified, potential borrow areas include some giant garter snake habitat; these areas would be avoided when feasible. Conservation Measure GGS-1 includes preconstruction surveys, avoidance of suitable giant garter snake habitat, restriction of ground disturbance in suitable habitat to the active season for giant garter snakes, and other measures to avoid and minimize harming giant garter snakes during construction (see Table 2-8). Conservation Measure GGS-2 includes restoration of giant garter snake habitat temporarily affected during construction.

Although construction may not directly affect certain areas of suitable habitat for giant garter snake, these areas may be indirectly affected by hydrologic changes in the San Joaquin River that would result from Project implementation. In the No-Action Alternative, much of the aquatic habitat in the Project area is maintained wet through much of the giant garter snake's summer active period by artificial impoundment of water behind Mendota Dam. The San Joaquin River arm of Mendota Pool extends to San Mateo Avenue in summer months, providing approximately 7 linear miles of slackwater habitat. Current management activities include drawing down Mendota Pool periodically during winter months and routing a portion of spring and early summer flood flows through Reach 2B; these management activities will continue under Alternative A. Although both of these activities could temporarily reduce prey base or habitat suitability for giant garter snake or western pond turtle, the margins of Mendota Pool areas near Mendota Dam and along the San Joaquin River arm are otherwise largely suitable for giant garter snake basking and foraging during most of their active period.

Project implementation would largely remove the San Joaquin arm of Mendota Pool. Alternative A would limit its extent to the Mendota Pool Dike; therefore, upstream aquatic conditions during the giant garter snake active period may vary over time and be a mix of slackwater, flowing water, and dry channel, which would likely be less suitable for giant garter snake than conditions currently found in Mendota Pool. Under Alternative A, the linear extent of the near-permanent slackwater habitat in the San Joaquin arm of Mendota Pool would be reduced to 0.6 mile. Although giant garter snakes would find suitable habitat in the Fresno Slough arm of Mendota Pool and may find some suitable habitat in the reconfigured river channel, compared to the No-Action Alternative, this would likely result in a reduction in potentially suitable habitat for giant garter snake. This could similarly affect western pond turtle, an aquatic turtle that is expected to prefer similar habitats in the Project area as giant garter snake. However, Conservation Measure GGS-2 includes compensation for the long-term loss of giant garter snake habitat at a ratio and in a manner determined through consultation with USFWS and DFW including specific measures such as the restoration and creation of suitable habitat (Table 2-8).

Long-term effects of Alternative A include passive restoration in the expanded floodplain. Floodplain habitat would include floodplain benches and floodplain channels inundated under high flow conditions (i.e., high flow channels) which would have lower velocities than the main channel (see Figure 2-3). This could provide some suitable habitat for giant garter snakes, western pond turtles, and their prey near the main channel of the river. Changes in flow regime that affect water temperature and velocity are not

expected to affect the other special-status reptile species (blunt-nosed leopard lizard, silvery legless lizard, San Joaquin coachwhip, and coast horned lizard). However, these special-status reptiles could benefit from the conversion of agricultural lands to restored natural habitat.

When comparing Alternative A to existing conditions, impacts to special-status reptile species would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). Temporary impacts during construction activities would vary spatially and occur intermittently within the overall construction timeframe for the entire Project, and most of the habitat for special-status reptiles affected would either be restored or remain as natural habitats at Project completion. Implementation of conservation measures would control or eradicate non-native invasive plants, which can negatively impact special-status reptiles. Conservation measures to avoid and minimize impacts, and/or to compensate for impacts, have been incorporated into the Project for blunt-nosed leopard lizard and giant garter snake. Avoidance, minimization, and compensation measures incorporated into the Project for giant garter snake would also benefit western pond turtle. Therefore, impacts to special-status reptile species are considered **less than significant**.

Impact WILD-3 (Alternative A): ***Project Effects on Special-Status Bird Species.*** Compared to the No-Action Alternative, Alternative A could affect special-status bird species (i.e., Swainson's hawk, white-tailed kite, greater sandhill crane, tricolored blackbird, greater white-fronted goose, short–eared owl, burrowing owl, redhead, mountain plover, northern harrier, lesser sandhill crane, loggerhead shrike, long-billed curlew, American white pelican, and yellow-headed blackbird) due to construction-related activities and habitat modifications. Direct effects of construction-related activities to special-status bird species include the potential mortality, injury or harassment of adults, juveniles, and nests due to construction vehicle traffic; the temporary use of land for staging and access areas; noise, light, and vibration from construction activities; and other site-preparation activities (i.e., grubbing, grading, tree removal, excavation, and driving off-road). Levee construction, removal, and protection, floodplain grading, and the placement of other Project infrastructure (i.e., South Canal bifurcation structure) would result in long-term conversion or modification of habitat that may support special-status bird species after construction is complete.

Almost all native bird species are protected broadly under the Migratory Bird Treaty Act. To avoid and minimize adverse effects to native birds, Conservation Measure MBTA-1 (Table 2-8) will restrict some Project activities to the non-breeding season. Conservation Measure MBTA-1 will also establish an Avian Protection Plan to further minimize and/or avoid adverse effects to native bird species. Direct effects on breeding raptor species would be avoided or minimized by implementation of Conservation Measures RAPTOR-1 and RAPTOR-2 (Table 2-8). These measures would restrict some construction activities to the non-breeding season to protect nests. If nests are found, a no-disturbance buffer would be established until birds have fledged. If any native trees suitable for raptor nesting are removed during Project activities, they would be replaced. Effects to riparian nesting birds would be avoided or minimized by Conservation Measure RNB-1 and

RNB-2. These measures require preconstruction surveys when riparian nesting birds are anticipated in the Project area, and construction avoidance and minimization measures.

Indirect effects of construction activities on birds may include creation of conditions in active work areas that attract opportunistic predators such as raccoons and domestic cats. Changes to vegetation type and structure, including the introduction of non-native invasive plant species, may decrease habitat suitability for foraging, nesting, or cover. Conservation Measure INV-1 (Table 2-8) would lessen the effects of invasive plant species by controlling and eradicating invasive plants where possible.

Implementation of Alternative A is likely to result in a combination of adverse effects as a result of construction, followed by long-term beneficial effects to special-status bird species. The placement of structures and levees would affect only a small proportion of habitat within the Project footprint (Table 7-5). Areas used for construction staging or access would be revegetated or returned to pre-project conditions; borrow areas would be disturbed during construction and revegetated at lower elevations (see Section 2.2.4). The analysis of effects to habitat for special-status bird species is based on species' association with specific habitats, but many of these species are capable of occurring across a variety of habitat types.

Implementation of Alternative A would affect habitat suitable for Swainson's hawk foraging and nesting (Table 7-5). To reduce the adverse effects of construction to Swainson's hawks, Conservation Measure SWH-1 requires preconstruction surveys for nesting Swainson's hawks. If nests are found, a no-disturbance buffer would be established until the nest is inactive. Most of the areas affected by Project activities would be passively returned to natural habitat, but a smaller portion would be converted to Project infrastructure or levees. Removal of foraging habitat or nesting trees will be compensated by establishing habitat suitable for foraging and nesting trees suitable for Swainson's hawks (Conservation Measure SWH-2, Table 2-8).

Burrowing owls require special consideration as, unlike other bird species addressed in this document, they live in underground burrows, making them particularly susceptible to ground disturbance, digging, and excavating. To protect burrowing owls and minimize effects, Conservation Measures BRO-1 and BRO-2 will be implemented (Table 2-8). These measures would decrease potential for adverse effects by avoiding work around active burrows. No-disturbance zones would be established around occupied burrows. Burrowing owls in the Project area would be passively relocated if they are not breeding. If occupied burrows are destroyed during construction, burrows outside of the active Project area would be enhanced or created to provide habitat for these birds.

Long-term effects of Alternative A include passive riparian habitat restoration in the floodplain. The continuation of Restoration Flows in the expanded floodplain would allow riparian vegetation to establish along previously bare banks of the San Joaquin River. This would provide greater foraging and/or nesting habitat for Swainson's hawks, white-tailed kites, and short-eared owls.

When comparing Alternative A to existing conditions, impacts to special-status bird species would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). Implementation of Alternative A should eventually result in a long-term net increase in the type and diversity of aquatic and riparian microhabitats associated with the river system. Project construction would require significant modifications to the existing levees, which would result in the loss of riparian nesting and foraging habitat. These impacts would be mostly temporary, and most of the habitat suitable for special-status birds would be allowed to return to riparian floodplain habitats or restored at Project completion. Avoidance, minimization, and conservation measures incorporated into the Project are broadly protective, reducing impacts to nesting activity for essentially all native birds. Additional measures would reduce impacts to raptors, with special attention to Swainson's hawk and burrowing owl. Loss of Swainson's hawk nesting and foraging habitat would be compensated. With the inclusion of these conservation measures, project impacts to special-status bird species are considered **less than significant.**

Impact WILD-4 (Alternative A): ***Project Effects on Special-Status Mammal Species.*** Compared to the No-Action Alternative, Alternative A could affect special-status mammal species (Fresno kangaroo rat, western mastiff bat, western red bat, and American badger) due to construction-related activities and habitat modifications. Construction-related activities, including construction vehicle traffic; temporary use of land for staging and access areas; noise, light, and vibration from construction activities; and other site-preparation activities (i.e., grubbing, grading, tree removal, excavation, and driving off-road) in suitable habitat for special-status mammals could result in mortality, injury, or harassment of special-status mammal species. Levee construction, removal, and protection, and the placement of other Project infrastructure (i.e., South Canal bifurcation structure) would result in long-term habitat conversion or modification of habitats that may support these mammal species after construction is complete.

Construction activities may attract opportunistic predators that may prey on special-status mammals. Lighted construction areas could disorient species and disrupt nocturnal foraging activities. Ground disturbance could lead to the temporary loss of foraging and burrowing habitat. Most of the adverse effects associated with construction are considered temporary. For most of the special-status mammal species, much of the affected habitat would be passively returned to natural conditions following Project construction (Table 7-5). Borrow areas, staging areas and temporary access roads would be stabilized (e.g., revegetated) or returned to pre-project conditions and function as habitat following implementation of Alternative A.

Potential construction effects on western red bats and western mastiff bats would be a temporary loss or change of foraging and roosting habitat from disturbance. In order to minimize effects to special-status bats, avoidance and minimization measures are incorporated into the Project (Table 2-8). Conservation Measure BAT-1 includes surveys for locating bat roosts prior to construction activities and excluding bats from active work zones during appropriate seasons. Any roosts removed or damaged during construction will be replaced with agency-approved and suitable bat boxes (Conservation Measure BAT-2).

Potential Fresno kangaroo rat habitat quality and quantity would diminish with implementation of Alternative A due to construction activities, though the amount of potential habitat that would be affected by Project activities is small (Table 7-5). Three areas with potentially suitable habitat on the eastern end of Reach 2B of the San Joaquin River were surveyed for Fresno kangaroo rat and none were detected (SJRRP 2011a). Access for surveys was not available in all areas of potentially suitable habitat on the south side of the river and there is a low to moderate potential for the species to occur there. If present, indirect effects on Fresno kangaroo rat from temporary habitat conversion could include shifts in foraging patterns or territories, increased predation, and decreased reproductive success. Alteration and compaction of soils would render portions of the potentially suitable habitat less suitable for Fresno kangaroo rat burrowing. To minimize the potential adverse effects of construction, preconstruction transect surveys would be conducted to locate potential burrows for Fresno kangaroo rats. If burrows are found within 100 feet of the Project footprint, focused live trapping surveys would be conducted by qualified biologists using approved methodologies. If necessary, additional conservation may be developed with USFWS and DFW. Construction activities in potential habitat would be timed to occur during the non-breeding season (FKR-1, Table 2-8).[3] Implementation of Conservation Measure FKR-3 will compensate for any temporary or long-term loss of habitat or take of individuals.

Although there is a low potential for San Joaquin kit fox to occur in the Project area, Conservation Measure SJKF-1 will be implemented to identify potential dens, avoid occupied dens near construction areas, and if dens are located within the proposed work area, time construction activities to avoid the normal breeding season.

Long-term effects of Alternative A include passive riparian habitat restoration in the floodplain. The continuation of Restoration Flows in the expanded floodplain would allow riparian vegetation to establish along previously bare banks of the San Joaquin River. This would provide greater foraging and roosting habitat for western red bats and more foraging habitat for western mastiff bats.

When comparing Alternative A to existing conditions, impacts to special-status mammals would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). Most of the project impacts would be limited to the duration of construction. Construction impacts would be temporary and would occur intermittently at discrete locations within the overall construction timeframe for the entire Project. Post-project conditions would passively return to natural habitats in much of the disturbed areas. Conservation measures that will be implemented for Alternative A are designed to minimize and avoid adverse impacts to special-status mammal species. With the inclusion of these measures, impacts of Alternative A to special-status mammals are considered **less than significant**.

Impact WILD-5 (Alternative A): ***Project Effects on Wildlife Movement Corridors.*** Compared to the No-Action Alternative, Alternative A could affect wildlife movement

[3] FKR-2 avoids disturbance to designated critical habitat for the species; there is no critical habitat for Fresno kangaroo rats within Reach 2B.

along migration corridors. Wildlife movement refers to localized, small distance movements made by animals within a home range; seasonal shifts for the purposes of locating food and water or breeding territory; larger dispersal movement of an individual between suitable habitats; and true trans-continental migrations. Many species, including most invertebrates, reptiles, and small mammals, are restricted to smaller distance migrations. A number of bird species (including Swainson's hawk, greater sandhill crane, greater white-fronted goose, redhead, mountain plover, northern harrier, lesser sandhill crane, loggerhead shrike, long-billed curlew, and American white pelican) make longer, seasonal migrations.

Construction activities such as vehicle traffic, the temporary use of land for staging and access areas, noise, light, vibration, and any other construction-related activities (e.g., grubbing, grading, tree removal, excavation, and driving off-road) may deter animals from using the area during migration. Construction may also result in the temporary destruction or degradation of habitat and the temporary loss of vegetated movement corridors. Direct mortality, injury, or harassment may also occur to species using the area for dispersal or migration. Construction activities may attract opportunistic predators (e.g., ravens, feral cats, and raccoons) that may feed on migrating species. Long-term construction effects include the conversion of small portions of a migration corridor to Project-related infrastructure, but also an overall expansion of habitat suitable for wildlife movement upon Project completion.

Only discrete subsections of the Project area would be under construction at any given time during the overall construction period, thereby reducing the severity of adverse effects associated with the creation of movement barriers. Wildlife would be able to move unobstructed through most of the Project area, particularly at night, throughout the duration of Project activities. In-channel construction activities will be limited to daylight hours during weekdays, leaving a nighttime and weekend periods available for wildlife movement along the river corridor (Conservation Measure EFH-2). Disturbance of riparian vegetation will also be avoided to the greatest extent practicable, as required by Conservation Measure EFH-1. Implementing Conservation Measure RHSNC-1 (Table 2-8) would minimize and avoid losses of riparian habitat. Implementing RHSNC-2 would compensate for any losses of riparian habitat or other sensitive natural communities.

Long-term effects of Alternative A include passive riparian habitat restoration in the floodplain. The continuation of Restoration Flows in the expanded floodplain would allow riparian vegetation to establish along previously bare banks of the San Joaquin River. This would provide cover and forage for animals moving along the river course. It would also provide more habitat for migratory bird species that may use the area as a stopping point for seasonal migrations. Post-project conditions would generally facilitate movement and provide habitat for many special-status species, including valley elderberry longhorn beetle, Swainson's hawk, white-tailed kite, tricolored blackbird, yellow-headed blackbird, and western red bat.

When comparing Alternative A to existing conditions, impacts to movement corridors would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). Most of these impacts would be temporary

and would occur intermittently within the overall construction timeframe for the entire Project. Most of the Project impacts would be limited to the duration of construction. Post-project conditions would return natural habitats to much of the disturbed areas and are expected to increase riparian vegetation, potentially improving conditions for migratory species. Impacts of Alternative A to movement corridors are considered **less than significant.**

Impact WILD-6 (Alternative A): ***Long-term Habitat Improvement in Reach 2B.*** Compared to the No-Action Alternative, Restoration Flows in Reach 2B would be conveyed through an expanded floodplain. Over time wetland communities would develop within the main channel and a dense riparian scrubland would develop along the main river channel banks. The Restoration Flows would be used to recruit new vegetation along the channel from the existing seed bank. Between the main river channel banks and the proposed levees, agricultural practices (e.g., annual crops, pasture, or floodplain-compatible permanent crops) would occur.

Passive riparian habitat restoration of the San Joaquin River would improve native floodplain and in-channel habitats, which would likely benefit native and potentially special-status species such as Swainson's hawk (*Buteo swainsoni*) and greater sandhill crane (*Grus canadensis tabida*). Benefits to native species would be realized through the re-introduction of perennial base flows as well as seasonal high flows in the river, which in turn would promote the establishment of riparian vegetation. Well-established native plant communities in the floodplain would support rich and diverse native flora, potentially including special-status plant species, and would provide foraging habitat and shelter for native wildlife species.

Alternative A supports the following wildlife habitat improvements:

- Restoring river-floodplain connectivity and longitudinal connectivity of riparian vegetation near the channel (without major breaks in the distribution of woody vegetation except where natural conditions prevent establishment of native trees or shrubs) that can provide cover and habitat for a variety of wildlife species.
- Creating or maintaining a combination of diverse habitats required by select wildlife species, such as species that depend on occurrence of aquatic, wetland or riparian, and upland habitats to meet various life stage requirements (e.g., western pond turtle, Swainson's hawk).
- Enhancing landscape connectivity between the river corridor and adjacent areas of ecological significance (e.g., wildlife refuges and other protected lands, biodiversity "hotspots," adjacent sloughs or tributary channels with existing riparian habitat, wildlife movement corridors, and natural preserves such as the Mendota Wildlife Area).

When comparing Alternative A to existing conditions, effects on long-term opportunities for habitat improvement in Reach 2B would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). According to habitat restoration estimates, Alternative A could provide up

to 1,330 acres of wildlife habitat and up to 1,070 acres of special-status species habitat (areas not mutually exclusive) (SJRRP 2012, Attachment A). For many of these habitat types, this represents a 2- to 5-fold increase in habitat as compared to existing conditions. In general, implementation of Alternative A would cause a **beneficial** effect on wildlife habitat.

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Alternative B would include construction of Project features including a Compact Bypass channel, a new levee system with a wide, consensus-based floodplain encompassing the river channel, and the Compact Bypass Bifurcation Structure with fish passage facility. Other key features include construction of a fish passage facility at the San Joaquin River control structure of Chowchilla Bifurcation Structure, the re-route of Drive 10 ½ (across the Compact Bypass bifurcation structure), and removal of the San Mateo Avenue crossing. Construction activity is expected to occur intermittently over an approximate 157-month timeframe.

This alternative includes a mixture of active and passive riparian and floodplain habitat restoration and compatible agricultural activities in the floodplain. It is assumed that wetland communities and a dense riparian scrubland would develop along the main channel and river banks, respectively, and bands of other habitat types (wetland, scrub, grassland, and forest) would develop at higher elevations along the channel corridor. Plantings that are wetland species or borderline wetland species would be irrigated and managed as necessary during the establishment period.

Table 7-6 summarizes maximum habitat impacts by acreage for all vertebrate species with the potential to occur in the Project area. These acreages represent the worst-case scenario where all existing floodplain areas are assumed to be impacted.

Table 7-6.
Species Habitat Potentially Affected by Alternative B

Scientific Name	Common Name	Habitat Type	Maximum Impacted Area (acres)			
			Floodplain	Infrastructure	Borrow	Other
			(future habitat)	(not future habitat)	(future habitat or agriculture)

Lasiurus blossevillii	Western red bat	Roosting and Foraging	829	116	350	24
Taxidea taxus	American badger	Habitat	140	15	200	5

Notes:
Floodplain = floodplain of the San Joaquin River (mixture of active and passive restoration and agricultural activities)
Infrastructure = structures, levees, or roads
Borrow = maximum amount disturbed to take fill materials for levees (reseeded)
Other = construction staging areas, temporary access roads, and other construction-related disturbances (reseeded)

Impact WILD-1 (Alternative B): ***Project Effects on Special-Status Invertebrate Species.*** Compared to the No-Action Alternative, Alternative B could affect special-status invertebrates. Construction-related effects on special-status invertebrate species would generally be the same as those described for Alternative A (see Impact WILD-1 [Alternative A]), with several exceptions.

Unlike Alternative A, Alternative B would use the Compact Bypass Bifurcation Structure to convey water from the San Joaquin River to Mendota Pool (and excludes the South Canal and associated levees). These infrastructure differences would result in effects on fewer elderberry shrubs, in comparison to Alternative A (i.e., one shrub in a riparian area and three shrubs in non-riparian areas). Up to 537 additional shrubs located in the future floodplain area are potentially affected. Conservation Measures VELB-1 and VELB-2 include pre-construction surveys for elderberry shrubs and beetle exit holes, avoidance of elderberry shrubs found in the Project area, and compensatory mitigation for shrubs unavoidable during construction (Table 2-8). Portions of the future floodplain areas would be allowed to return to natural habitats after Project construction is complete, which would provide suitable habitat for elderberry shrubs after construction is complete, especially along the main river channel banks where many of the elderberry shrubs occur now. Alternative B also features a wide, consensus-based floodplain and a mixture of active and passive restoration and floodplain compatible agricultural activities. These features would result in more riparian habitat over the long-term and presumably more valley elderberry longhorn beetle habitat than Alternative A.

Construction activity under Alternative B is expected to take 157 months; therefore, adverse effects of construction would occur over an approximately 2 years longer period as compared to Alternative A.

When comparing Alternative B to existing conditions, impacts to special-status invertebrates would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative B to the No-Action Alternative). Because these impacts would be temporary and would occur intermittently within the overall construction timeframe, and because conservation measures are in place to reduce, minimize, and compensate for impacts, they are considered **less than significant**.

Impact WILD-2 (Alternative B): ***Project Effects on Special-Status Reptile Species.*** Compared to the No-Action Alternative, Alternative B could affect special-status reptile species. Construction-related effects on special-status reptile species would generally be the same as those described for Alternative A (see Impact WILD-2 [Alternative A]), with several exceptions.

Unlike Alternative A, Alternative B would create a wide, consensus-based floodplain. This change would result in adverse effects on slightly less habitat for most special-status reptiles compared to Alternative A (see Table 7-6). Alternative B would affect nearly the same amount of potential habitat for blunt-nosed leopard lizard as Alternative A, but a smaller portion of the habitat affected would be converted to Project infrastructure than under Alternative A, potentially resulting in a smaller long-term effect on this species (if present). All adverse effects would be avoided and/or mitigated with implementation of the Conservation Measures BNLL-1 and BNLL-2 (Table 2-8). As a fully-protected species, direct take of blunt-nosed leopard lizards would be prohibited.

Alternative B would affect slightly less potential habitat for giant garter snake than Alternative A, and more of the potential habitat affected under Alternative B would remain as or be restored to natural habitats upon Project completion, resulting in a potentially reduced long-term effect on this species in comparison to Alternative A. Similar to Alternative A, measures would be implemented to minimize these adverse effects to special-status reptiles (see Impact WILD-2 [Alternative A] and Table 2-8).

The Mendota Pool control structure of the Compact Bypass Bifurcation Structure (Alternative B) would be in the same location as the Mendota Pool Dike (Alternative A). Therefore, both of these alternatives would provide equivalent amounts of slackwater habitat for giant garter snake in the San Joaquin River arm of Mendota Pool (see Impact WILD-2 [Alternative A]) following Project completion.

When comparing Alternative B to existing conditions, impacts to special-status reptiles would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative B to the No-Action Alternative). Because these impacts would occur intermittently within the overall construction timeframe, and conservation measures are in place to reduce, minimize, and compensate for impacts, they are considered **less than significant**.

Impact WILD-3 (Alternative B): ***Project Effects on Special-Status Bird Species.*** Compared to the No-Action Alternative, Alternative B could affect special-status bird species. Construction-related effects on special-status bird species would generally be the same as those described for Alternative A (see Impact WILD-3 [Alternative A]), with several exceptions.

Unlike Alternative A, Alternative B would create a wide, consensus-based floodplain. This change would result in adverse effects on slightly more habitat for most special-status birds than Alternative A (see Table 7-6). However, most of this habitat would remain as or be restored to native habitats upon Project completion. Similar to Alternative A, measures would be implemented to minimize adverse effects to special-status birds (see Impact WILD-3 [Alternative A] and Table 2-8).

The wide floodplain featured in Alternative B may provide more foraging and/or nesting habitat (compared to the narrow floodplain) for a number of species, including the Northern harrier, greater sandhill crane, Swainson's hawk, long-billed curlew, and short-eared owl, compared to both Alternative A and the No-Action Alternative. Under Alternative B, the floodplain and associated riparian habitat would include active restoration areas, whereas under Alternative A, passive restoration would depend on the availability of the existing seed bank and seed sources. Following construction of Alternative B Project components, wetland, floodplain, and riparian areas in the active restoration portion would be planted and irrigated until vegetation was established (see Chapter 2.0, "Description of Alternatives"). This could result in more rapid development of riparian habitat important to birds following construction.

When comparing Alternative B to existing conditions, impacts to special-status birds would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative B to the No-Action Alternative). Because the majority of these impacts would be temporary and would occur intermittently within the overall construction timeframe, because conservation measures are in place to reduce and minimize impacts, and because active restoration of riparian habitats would occur, they are considered **less than significant**.

Impact WILD-4 (Alternative B): ***Project Effects on Special-Status Mammal Species.*** Compared to the No-Action Alternative, Alternative B could affect special-status mammal species. Construction-related effects on special-status mammal species would generally be the same as those described for Alternative A (see Impact WILD-4 [Alternative A]), with several exceptions.

Unlike Alternative A, Alternative B would create a wide, consensus-based floodplain. The wide floodplain would generally affect more habitat for special-status mammals during construction, including areas near the river and at temporary staging areas, than Alternative A (see Table 7-6). However, most of this habitat would remain unchanged or be restored to natural habitats upon Project completion and less habitat would be converted to Project infrastructure. Similar to Alternative A, measures would be implemented to minimize these adverse effects to special-status mammals (see Impact WILD-4 [Alternative A] and Table 2-8). Following Project completion under Alternative

B, fewer acres of potential habitat for special-status mammals would be converted to infrastructure, as compared to Alternative A.

The wide floodplain featured in Alternative B may provide more foraging habitat (compared to the narrow floodplain in Alternative A or the No-Action Alternative) for bat species. Under this alternative, portions of the floodplain and associated riparian habitat would be actively restored. Following construction of Alternative B Project components, wetland, floodplain, and riparian areas in the active restoration portion would be planted and irrigated until vegetation is established (see Chapter 2.0, "Description of Alternatives").

When comparing Alternative B to existing conditions, impacts to special-status mammals would generally be the same as described in the preceding paragraphs (i.e., the comparison of Alternative B to the No-Action Alternative). Because impacts would be temporary and would occur intermittently within the overall construction timeframe, conservation measures are in place to reduce and minimize impacts, and active restoration of riparian habitats would occur, the impacts are considered **less than significant**.

Impact WILD-5 (Alternative B): ***Adverse Effects on Wildlife Movement Corridors.*** Compared to the No-Action Alternative, Alternative B could affect wildlife movement along migration corridors. Construction-related effects on migration corridors would generally be the same as those described for Alternative A (see Impact WILD-5 [Alternative A]), with several exceptions.

Unlike Alternative A, Alternative B would create a wide, consensus-based floodplain, which would provide a larger riparian corridor for movement. Project construction periods would be longer than Alternative A, but post-project conditions would most likely improve habitat for migrating species, especially because portions of the floodplain would be actively restored for Alternative B.

When comparing Alternative B to existing conditions, impacts to movement corridors would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative B to the No-Action Alternative). Most of these impacts would be temporary and would occur intermittently within the overall construction timeframe for the entire Project. Post-project conditions would return natural habitats to much of the disturbed areas and are expected to increase riparian vegetation, potentially improving conditions for migratory species. Impacts of Alternative B to movement corridors are considered **less than significant.**

Impact WILD-6 (Alternative B): ***Long-term Habitat Improvement in Reach 2B.*** Compared to the No-Action Alternative, Restoration Flows in Reach 2B would be conveyed through an expanded floodplain. Wetland communities would develop within the main channel, a dense riparian scrubland would develop along the main river channel banks, and bands of other habitat types (wetland, scrub, grassland, and forest) would develop at higher elevations along the channel corridor. The wetland, floodplain, and

riparian areas in the active restoration portion would be planted following construction and then irrigated and managed as necessary during the establishment period.

Active riparian and floodplain habitat restoration would improve native floodplain and in-channel habitats, which would likely benefit native and potentially special-status species. Benefits to native species would be realized through the re-introduction of perennial base flows as well as seasonal high flows in the river, which in turn would promote the establishment of riparian vegetation. Well-established native plant communities in the floodplain would support rich and diverse native flora, potentially including special-status plant species, and would provide foraging habitat and shelter for native wildlife species.

When comparing Alternative B to existing conditions, effects on long-term opportunities for habitat improvement in Reach 2B would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative B to the No-Action Alternative). According to habitat restoration estimates, Alternative B could provide up to 1,870 acres of wildlife habitat and up to 1,640 acres of special-status species habitat (not mutually exclusive areas) (SJRRP 2012, Attachment A). For many of these habitat types, this represents a 3- to 9-fold increase in habitat as compared to existing conditions. In general, implementation of Alternative B would cause a **beneficial** effect on wildlife habitat.

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Alternative C would include construction of Project features including Fresno Slough Dam, a new levee system with a narrow floodplain encompassing the river channel, and the Short Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the Short Canal control structure and fish screen, the Chowchilla Bifurcation Structure fish passage facility, modification of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 133-month timeframe.

Similar to Alternative B, Alternative C includes active riparian and floodplain habitat restoration. It is assumed that wetland communities and a dense riparian scrubland would develop along the main channel and river banks, respectively, and bands of other habitat types (wetland, scrub, grassland, and forest) would develop at higher elevations along the channel corridor. The wetland, floodplain, and riparian areas would be planted following construction and then irrigated and managed as necessary during the establishment period.

Table 7-7 summarizes habitat impacts by acreage for all vertebrate species. These acreages represent the worst-case scenario where all existing floodplain areas are assumed to be impacted.

Table 7-7.
Species Habitat Potentially Affected by Alternative C

Scientific Name	Common Name	Habitat Type	Maximum Impacted Area (acres)

Lasiurus blossevillii	Western red bat	Roosting and Foraging	754	110	350	48
Taxidea taxus	American badger	Habitat	158	14	200	11

Notes:
Floodplain = floodplain of the San Joaquin River (active restoration)
Infrastructure = structures, levees, or roads
Borrow = maximum amount disturbed to take fill materials for levees (reseeded)
Other = construction staging areas, temporary access roads, and other construction-related disturbances (reseeded)

Impact WILD-1 (Alternative C): ***Project Effects on Special-Status Invertebrate Species.*** Compared to the No-Action Alternative, Alternative C could affect special-status invertebrate species. Construction-related effects on special-status invertebrate species would generally be the same as those described for Alternative A (see Impact WILD-1 [Alternative A]), with several exceptions.

Unlike Alternative A, Alternative C would use the river channel for Restoration Flow and the Short Canal to convey water from the San Joaquin River to Mendota Pool (and excludes the South Canal and associated levees). These infrastructure differences would result in effects on fewer elderberry shrubs, in comparison to Alternative A (i.e., one shrub in riparian areas and three shrubs in non-riparian areas). Up to 537 additional shrubs located in the future floodplain area are potentially affected. Conservation Measures VELB-1 and VELB-2 include pre-construction surveys for elderberry shrubs and beetle exit holes, avoidance of elderberry shrubs found in the Project area, and compensatory mitigation for shrubs unavoidable during construction (Table 2-8). Future floodplain areas would be allowed to return to natural habitats after Project construction is complete, which would provide suitable habitat for elderberry shrubs after construction is complete, especially along the main river channel banks where many of the elderberry

shrubs occur now. Though both Alternatives A and C include plans for a narrow floodplain, Alternative C features active riparian and floodplain restoration and would not include agricultural or grazing use within the floodplain. Implementation of Alternative C would result in more riparian habitat over the long-term and potentially more valley elderberry longhorn beetle habitat than Alternative A.

Construction activity under Alternative C is expected to take 133 months, which is a similar duration as Alternative A.

When comparing Alternative C to existing conditions, impacts to special-status invertebrate species would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative C to the No-Action Alternative). Because unavoidable impacts would be compensated for through implementation of the Project conservation measures and because the completed Project would provide habitat for elderberry shrubs, the impacts are considered **less than significant**.

Impact WILD-2 (Alternative C): ***Project Effects on Special-Status Reptile Species.*** Compared to the No-Action Alternative, Alternative C could affect some special-status reptile species. Construction-related effects on special-status reptile species would generally be the same as those described for Alternative A (see Impact WILD-1 [Alternative A]), with several exceptions.

Unlike Alternative A, Alternative C would include the construction of the Fresno Slough Dam and the Short Canal. This change would result in adverse effects to slightly more habitats for special-status reptiles in areas near the river, compared to Alternative A (see Table 7-7). Under Alternative C, less habitat area would be converted to Project infrastructure for most special-status reptile species, with the exception of the aquatic and wetland habitats for the giant garter snake and the western pond turtle. Alternative C would use the river channel to convey Restoration Flows through Reach 2B (instead of a Compact Bypass). This method essentially removes the slackwater habitat for giant garter snake in the San Joaquin arm of Mendota Pool following Project completion. Whereas, Alternative A would retain a small portion of slackwater habitat between the Mendota Dam and the Mendota Pool Dike (see Impact WILD-2 [Alternative A]). Similar to Alternative A, measures would be implemented to minimize these adverse effects to special-status reptiles (see Impact WILD-2 (Alternative A) and Table 2-8).

Alternative C would affect nearly the same amount of potential habitat for blunt-nosed leopard lizard as Alternative A, but a larger portion of the habitat affected would be converted to Project infrastructure than under Alternative A, potentially resulting in a greater long-term effect on this species (if present). All adverse effects would be avoided and/or mitigated with implementation of the Conservation Measures BNLL-1 and BNLL-2 (Table 2-8). As a fully-protected species, direct take of blunt-nosed leopard lizards would be prohibited.

When comparing Alternative C to existing conditions, impacts to special-status reptiles would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative C to the No-Action Alternative). Because these impacts would be largely

temporary, would occur intermittently within the overall construction timeframe, and because conservation measures are in place to reduce, minimize, and compensate for impacts, they are considered **less than significant.**

Impact WILD-3 (Alternative C): ***Project Effects on Special-Status Bird Species.*** Compared to the No-Action Alternative, Alternative C could affect special-status bird species. Construction-related effects on special-status bird species would generally be the same as those described for Alternative A (see Impact WILD-1 [Alternative A]), with several exceptions. Unlike Alternative A, Alternative C would include the construction of the Fresno Slough Dam and the Short Canal. This change would result in temporary adverse effects to more habitat for most special-status birds than Alternative A (see Table 7-7) but for most species, less of this habitat would be converted to Project infrastructure. Similar to Alternative A, measures would be implemented to minimize these adverse effects to special-status birds (see Impact WILD-3 (Alternative A) and Table 2-8).

Though both Alternatives A and C include plans for a narrow floodplain, Alternative C features active riparian and floodplain restoration and would not include agricultural or grazing use within the floodplain. Implementation of Alternative C would result in more riparian habitat, and thus available nesting habitat for Swainson's hawks, white-tailed kites, and short-eared owls. In comparison to Alternative A and the No-Action Alternative, post-project conditions may provide less foraging habitat for birds that use open, grassland or crop cover, including mountain plovers, loggerhead shrikes, long-billed curlews, and yellow-headed blackbirds.

When comparing Alternative C to existing conditions, impacts to special-status birds would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative C to the No-Action Alternative). Because the majority of these impacts would be temporary and would occur intermittently within the overall construction timeframe, conservation measures are in place to reduce and minimize impacts, and active restoration of riparian habitats would occur, they are considered **less than significant**.

Impact WILD-4 (Alternative C): ***Project Effects on Special-Status Mammal Species.*** Compared to the No-Action Alternative, Alternative C could affect special-status mammal species. Construction-related effects on special-status mammal species would generally be the same as those described for Alternative A (see Impact WILD-4 [Alternative A]), with several exceptions.

Unlike Alternative A, Alternative C would include the construction of the Fresno Slough Dam and the Short Canal. These changes would convert less habitat area for special-status mammals to Project infrastructure, though slightly more habitat area would be affected temporarily for most species (see Table 7-7). Similar to Alternative A, measures would be implemented to minimize these adverse effects to special-status mammals (see Impact WILD-4 [Alternative A] and Table 2-8).

Following construction of Alternative C Project components, wetland, floodplain, and riparian areas would be planted and irrigated until vegetation is established (see Chapter 2.0, "Description of Alternatives"). Though both Alternatives A and C include plans for a

narrow floodplain, active restoration and restriction of agricultural or grazing use within the floodplain would result in more riparian habitat, which would be beneficial to the western red bat and the western mastiff bat.

When comparing Alternative C to existing conditions, impacts to special-status mammals would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative C to the No-Action Alternative). Because impacts would be temporary and would occur intermittently within the overall construction timeframe, conservation measures are in place to reduce and minimize impacts, and active restoration of riparian habitats would occur, the impacts are considered **less than significant**.

Impact WILD-5 (Alternative C): *Adverse Effects on Wildlife Movement Corridors.* Compared to the No-Action Alternative, Alternative C could affect wildlife movement along migration corridors. Construction-related effects on migration corridors would generally be the same as those described for Alternative A (see Impact WILD-5 [Alternative A]), with several exceptions.

Following construction of Alternative C Project components, wetland, floodplain, and riparian areas would be planted and irrigated until vegetation is established (see Chapter 2.0, "Description of Alternatives"). Though both Alternatives A and C include plans for a narrow floodplain, this active restoration and restriction of agricultural or grazing use within the floodplain would result in more riparian habitat, potentially providing better cover and forage for migrating wildlife.

When comparing Alternative C to existing conditions, impacts to movement corridors would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative C to the No-Action Alternative). Most of these impacts would be temporary and would occur intermittently within the overall construction timeframe for the entire Project. Post-project conditions would return natural habitats to much of the disturbed areas and are expected to increase riparian vegetation, potentially improving conditions for migratory species. Impacts of Alternative C to movement corridors are considered **less than significant.**

Impact WILD-6 (Alternative C): *Long-term Habitat Improvement in Reach 2B.* Compared to the No-Action Alternative, Restoration Flows in Reach 2B would be conveyed through an expanded floodplain. Wetland communities would develop within the main channel, a dense riparian scrubland would develop along the main river channel banks, and bands of other habitat types (wetland, scrub, grassland, and forest) would develop at higher elevations along the channel corridor. The wetland, floodplain, and riparian areas would be planted following construction and then irrigated and managed as necessary during the establishment period.

Active riparian and floodplain habitat restoration would improve native floodplain and in-channel habitats, which would likely benefit native and potentially special-status species. Benefits to native species would be realized through the re-introduction of perennial base flows as well as seasonal high flows in the river, which in turn would promote the establishment of riparian vegetation. Well-established native plant

communities in the floodplain would support rich and diverse native flora, potentially including special-status plant species, and would provide foraging habitat and shelter for native wildlife species.

When comparing Alternative C to existing conditions, effects on long-term opportunities for habitat improvement in Reach 2B would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative C to the No-Action Alternative). According to habitat restoration estimates, Alternative C could provide up to 1,360 acres of wildlife habitat and up to 1,050 acres of special-status species habitat (not mutually exclusive areas) (SJRRP 2012, Attachment A). For many of these habitat types, this represents a 2- to 5-fold increase in habitat as compared to existing conditions. In general, implementation of Alternative C would cause a **beneficial** effect on wildlife habitat.

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Alternative D would include construction of Project features including Fresno Slough Dam, a new levee system with a wide floodplain encompassing the river channel, and the North Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the North Canal bifurcation structure, and the North Canal fish passage facility, removal of the San Joaquin River control structure of the Chowchilla Bifurcation Structure, removal of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 158-month timeframe.

Similar to Alternative A, Alternative D includes passive riparian habitat restoration and agricultural practices in the floodplain. It is assumed that over time wetland communities and a dense riparian scrubland would develop along the main channel and river banks, respectively. The Restoration Flows would be used to recruit new vegetation along the channel from the existing seed bank. Between the main river channel banks and the proposed levees, limited agricultural practices (e.g., pasture) would occur.

Table 7-8 summarizes habitat impacts by acreage for all vertebrate species with the potential to occur in the Project area. These acreages represent the worst-case scenario where all existing floodplain areas are assumed to be impacted.

Table 7-8.
Species Habitat Potentially Affected by Alternative D

Taxidea taxus	American badger	Habitat	149	19	200	9

Notes:
Floodplain = floodplain of the San Joaquin River (passive restoration and agricultural activities)
Infrastructure = structures, levees, or roads
Borrow = maximum amount disturbed to take fill materials for levees (reseeded)
Other = construction staging areas, temporary access roads, and other construction-related disturbances (reseeded)

Impact WILD-1 (Alternative D): ***Project Effects on Special-Status Invertebrate Species.*** Compared to the No-Action Alternative, Alternative D could affect special-status invertebrate species. Construction-related effects on special-status invertebrate species would generally be the same as those described for Alternative A (see Impact WILD-1 [Alternative A]), with several exceptions.

Unlike Alternative A, Alternative D would use the river channel for Restoration Flows and the North Canal to convey water from the San Joaquin River to Mendota Pool. These infrastructure differences would result in fewer effects on elderberry shrubs, in comparison to Alternative A (i.e., 13 shrubs from riparian areas and 3 shrubs from non-riparian areas). Up to 523 additional shrubs located in the future floodplain area are potentially affected. Conservation Measures VELB-1 and VELB-2 include pre-construction surveys for elderberry shrubs and beetle exit holes, avoidance of elderberry shrubs found in the Project area, and compensatory mitigation for shrubs unavoidable during construction (Table 2-8). The future floodplain area would be allowed to return to

natural habitats after Project construction is complete, which would provide suitable habitat for elderberry shrubs after construction is complete, especially along the main river channel banks where many of the elderberry shrubs occur now.

Construction activity under Alternative D is expected to take 158 months, therefore, adverse effects of construction would occur over an approximately 2 year longer period compared to Alternative A. Alternatives A and D both allow for agricultural or grazing use within the floodplain.

When comparing Alternative D to existing conditions, impacts to special-status invertebrate species would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative D to the No-Action Alternative). Because unavoidable impacts would be compensated for through implementation of the Project conservation measures and because the completed Project would provide habitat for elderberry shrubs, the impacts are considered **less than significant**.

Impact WILD-2 (Alternative D): ***Project Effects on Special-Status Reptile Species*****.** Compared to the No-Action Alternative, Alternative D could affect some special-status reptile species. Construction-related effects on special-status reptile species would generally be the same as those described for Alternative A (see Impact WILD-1 [Alternative A]), with several exceptions.

The features of Alternative D would displace more habitat for silvery legless lizards. Habitats converted to Project infrastructure would be less for the other special-status reptile species, excepting the aquatic and wetland habitats for the giant garter snake and the western pond turtle (see Table 7-8). Alternative D would use the river channel to convey Restoration Flows through Reach 2B (instead of a Compact Bypass). This method essentially removes the slackwater habitat for giant garter snake in the San Joaquin arm of Mendota Pool following Project completion (see Impact WILD-2 [Alternative A]). Similar to Alternative A, measures would be implemented to minimize adverse effects to special-status reptiles (see Impact WILD-2 [Alternative A] and Table 2-8).

Alternative D would potentially affect slightly less total habitat for blunt-nosed leopard lizard than Alternative A and less of the habitat affected would be converted to Project infrastructure. All adverse effects would be avoided and/or mitigated with implementation of the Conservation Measures BNLL-1 and BNLL-2 (Table 2-8). As a fully-protected species, direct take of blunt-nosed leopard lizards would be prohibited.

Construction activity under Alternative D is expected to take 158 months, therefore, adverse effects of construction would occur over an approximately 2 year longer period compared to Alternative A.

When comparing Alternative D to existing conditions, impacts to special-status reptiles would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative D to the No-Action Alternative). Because these impacts would be largely temporary, would occur intermittently within the overall construction timeframe, and

conservation measures are in place to reduce, minimize, and compensate for impacts, they are considered **less than significant.**

Impact WILD-3 (Alternative D): *Project Effects on Special-Status Bird Species*. Compared to the No-Action Alternative, Alternative D could affect special-status bird species. Construction-related effects on special-status bird species would generally be the same as those described for Alternative A (see Impact WILD-1 [Alternative A]), with several exceptions.

Unlike Alternative A, Alternative D would include the construction of the Fresno Slough Dam and the North Canal. These changes would result in adverse effects to more habitat for all of the special-status birds in areas near the river, than Alternative A (see Table 7-8). For a few of these species (including the nesting habitats of burrowing owls, tricolored blackbirds, short-eared owls, and northern harriers), less of this habitat would be converted to long-term infrastructure. Similar to Alternative A, measures would be implemented to minimize these adverse effects to special-status birds (see Impact WILD-3 (Alternative A) and Table 2-8).

Both Alternatives A and D allow for agricultural or grazing use within the floodplain. In comparison to Alternative A (narrow floodplain), post-project conditions of Alternative D (wide floodplain) may provide more foraging habitat for birds that use open, grassland or crop cover, including mountain plovers, loggerhead shrikes, long-billed curlews, and yellow-headed blackbirds.

Construction activity under Alternative D is expected to take 158 months, therefore, adverse effects of construction would occur over an approximately 2 year longer period compared to Alternative A.

When comparing Alternative D to existing conditions, impacts to special-status birds would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative D to the No-Action Alternative). Because the majority of these impacts would be temporary and would occur intermittently within the overall construction timeframe, conservation measures are in place to reduce and minimize impacts, and active restoration of riparian habitats would occur, they are considered **less than significant**.

Impact WILD-4 (Alternative D): *Project Effects on Special-Status Mammal Species.* Compared to the No-Action Alternative, Alternative D could affect special-status mammal species. Construction-related effects on special-status mammal species would generally be the same as those described for Alternative A (see Impact WILD-4 [Alternative A]), with several exceptions.

Unlike Alternative A, Alternative D would include the construction of the Fresno Slough Dam and North Canal. More habitat for special-status mammal species would be disturbed by construction activities near the river, though less habitat for American badgers and Fresno kangaroo rats would be converted to Project infrastructure (see Table 7-8). Similar to Alternative A, measures would be implemented to minimize these

adverse effects to special-status mammals (see Impact WILD-4 [Alternative A] and Table 2-8).

Construction activity under Alternative D is expected to take 158 months, therefore, adverse effects of construction would occur over an approximately 2 year longer period compared to Alternative A.

When comparing Alternative D to existing conditions, impacts to special-status mammals would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative D to the No-Action Alternative). Because these impacts would be temporary and would occur intermittently within the overall construction timeframe, conservation measures are in place to reduce and minimize impacts, and active restoration of riparian habitats would occur, the impacts are considered **less than significant**.

Impact WILD-5 (Alternative D): ***Adverse Effects on Wildlife Movement Corridors*****.** Compared to the No-Action Alternative, Alternative D could affect wildlife movement along migration corridors. Construction-related effects on migration corridors would generally be the same as those described for Alternative A (see Impact WILD-5 [Alternative A]), with several exceptions**.**

Alternative A includes plans for a San Mateo Avenue crossing. In Alternative D, this crossing would be removed. This would not alter bird movement, but the crossing may provide a way for other terrestrial species to cross the river. Compared to the No-Action Alternative, the restoration of a riparian corridor would facilitate movement and provide habitat for many special-status species, including valley elderberry longhorn beetles, Swainson's hawks, white-tailed kites, tricolored blackbirds, yellow-headed blackbirds and western red bats.

When comparing Alternative D to existing conditions, impacts to movement corridors would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative D to the No-Action Alternative). Most of these impacts would be temporary and would occur intermittently within the overall construction timeframe for the entire Project. Post-project conditions would return natural habitats to much of the disturbed areas and are expected to increase riparian vegetation, potentially improving conditions for migratory species. Impacts of Alternative D to movement corridors are considered **less than significant.**

Impact WILD-6 (Alternative D): ***Long-term Habitat Improvement in Reach 2B*****.** Compared to the No-Action Alternative, Restoration Flows in Reach 2B would be conveyed through an expanded floodplain. Over time wetland communities would develop within the main channel and a dense riparian scrubland would develop along the main river channel banks. The Restoration Flows would be used to recruit new vegetation along the channel from the existing seed bank. Between the main river channel banks and the proposed levees, limited agricultural practices (e.g., pasture) would occur.

Passive riparian habitat restoration of the San Joaquin River would improve native floodplain and in-channel habitats, which would likely benefit native and potentially

special-status species such as Swainson's hawk and greater sandhill crane. Benefits to native species would be realized through the re-introduction of perennial base flows as well as seasonal high flows in the river, which in turn would promote the establishment of riparian vegetation. Well-established native plant communities in the floodplain would support rich and diverse native flora, including potentially special-status plant species, and would provide foraging habitat and shelter for native wildlife species.

When comparing Alternative D to existing conditions, effects on long-term opportunities for habitat improvement in Reach 2B would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative D to the No-Action Alternative). According to habitat restoration estimates, Alternative D could provide up to 1,900 acres of wildlife habitat and up to 1,630 acres of special-status species habitat (not mutually exclusive areas) (SJRRP 2012, Attachment A). For many of these habitat types, this represents a 3- to 9-fold increase in habitat as compared to existing conditions. In general, implementation of Alternative D would cause a **beneficial** effect on wildlife habitat.

8.0 Climate Change and Greenhouse Gas Emissions

This chapter describes the environmental and regulatory setting for climate change and greenhouse gas emissions, as well as the environmental consequences associated with the construction and operation of Project alternatives, including impacts and mitigation measures.

8.1 Environmental Setting

8.1.1 Greenhouse Gases

Radiation from the sun is the primary source of energy keeping the earth warm enough for life. Solar radiation enters the earth's atmosphere, a portion of the radiation passes through the atmosphere and is absorbed by the earth's surface (this is primarily radiation in the visible portion of the electromagnetic spectrum), a portion is reflected back toward space, and a portion is absorbed by the upper atmosphere. The radiation absorbed by the earth heats the earth's surface which then emits infrared radiation. Since the earth has a much lower temperature than the sun, it emits longer wavelength radiation.[1]

Certain gases in the earth's atmosphere, classified as greenhouse gases (GHGs), play a critical role in determining the earth's surface temperature. GHGs have strong absorption properties at wavelengths that are emitted by the earth. As a result, radiation that otherwise would have escaped back into space is instead "trapped," resulting in a warming of the atmosphere. This phenomenon, known as the "greenhouse effect," is responsible for maintaining a habitable climate on Earth.

Prominent GHGs contributing to the greenhouse effect are water vapor, carbon dioxide (CO_2), methane, ozone, nitrous oxide (N_2O), and fluorinated compounds (chlorofluorocarbons, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride). Human-caused emissions of these GHGs in excess of natural ambient concentrations are responsible for intensifying the greenhouse effect and have led to a warming trend of the earth's climate, known as global climate change or global warming. Global temperatures have increased over the past 50 years and it is unlikely that the increase can be explained without the contribution of GHGs from human activities (Intergovernmental Panel on Climate Change [IPCC] 2014).

Although preliminary research has also found localized effects from GHGs, climate change is largely a global problem. GHGs pollutants have global implications, unlike criteria air pollutants and toxic air contaminants, which are pollutants of regional and local concern. Whereas pollutants with localized air quality effects have relatively short

[1] The wavelength at which a body emits radiation is proportional to the temperature of the body.

atmospheric lifetimes (e.g., about 1 day), GHGs have long atmospheric lifetimes (1 year to several thousand years). GHGs persist in the atmosphere for long enough time periods to be dispersed around the globe. CO_2 is one of the major human contributed GHGs. Of the total annual human-caused CO_2 emissions, less than 45 percent is sequestered (removed from the atmosphere and stored) through ocean uptake, uptake by northern hemisphere forest regrowth, and other terrestrial sinks. The remaining human-caused CO_2 emissions remain stored in the atmosphere (IPCC 2014, Ballantyne et al. 2012).

The atmosphere and the oceans are reaching their capacity to absorb CO_2 and other GHGs, without significantly changing the Earth's climate. The increase in GHGs in the Earth's climate is projected to affect a wide range of issues and resources, including sea-level rise, flooding, water supply, agricultural and forestry resources, and energy demand. California's Climate Change Portal (www.climatechange.ca.gov) states:

> *Climate change is expected to have significant, widespread impacts on California's economy and environment. California's unique and valuable natural treasures - hundreds of miles of coastline, high value forestry and agriculture, snow-melt fed fresh water supply, vast snow and water fueled recreational opportunities, as well as other natural wonders - are especially at risk.*

In addition, the IPCC, in the section of its Fifth Assessment Report by Working Group II, "Climate Change 2014: Impacts, Adaptation, and Vulnerability" (IPCC 2014; released March 31, 2014), specific to North America (Chapter 26), stated in part:

> *North American ecosystems are under increasing stress from rising temperatures, CO_2 concentrations, and sea-levels, and are particularly vulnerable to climate extremes (very high confidence). Climate stresses occur alongside other anthropogenic influences on ecosystems, including land-use changes, non-native species, and pollution, and in many cases will exacerbate these pressures (very high confidence) [26.4.1; 26.4.3]. Evidence since the Fourth Assessment Report (IPCC 2007) highlights increased ecosystem vulnerability to multiple and interacting climate stresses in forest ecosystems, through wildfire activity, regional drought, high temperatures, and infestations (medium confidence) [26.4.2.1; Box 26-2]; and in coastal zones due to increasing temperatures, ocean acidification, coral reef bleaching, increased sediment load in run-off, sea level rise, storms, and storm surges (high confidence) [26.4.3.1].*

California has already been affected by climate change: sea-level rise, increased average temperatures, more extreme hot days and increased heat waves, fewer shifts in the water cycle, and increased frequency and intensity of wildfires. Higher sea levels can result in increased coastal erosion (which may have a secondary effect, such as uncovering shoreline hazards), more frequent flooding from storm surges, increased property damage, and reduced waterfront public access options. Other projected climate change impacts in California include: decreases in the water quality of surface waterbodies, groundwater, and coastal waters; decline in aquatic ecosystem health; lowered profitability for water-intensive crops; changes in species and habitat distribution; and

impacts to fisheries (California Regional Assessment Group 2002). These effects are expected to increase with rising GHG levels in the atmosphere.

The quantity of GHGs that it takes to cause a change in climate is not precisely known; however, the quantity is enormous. The estimated global annual emission of anthropogenic GHGs was 46 billion metric tons in 2010 (U.S. Environmental Protection Agency [EPA] 2014a). Of this, agriculture was estimated to contribute about 11.5 percent, or about 5.3 billion metric tons of GHGs (Food and Agriculture Organization of the United Nations 2014). This compares with the estimated emissions from California of 0.453 billion metric tons or about 1 percent of the global emissions (California Air Resources Board [ARB] 2014a). Emissions of GHGs contributing to global climate change are attributable in large part to human activities associated with the burning of fossil fuels, industrial/manufacturing, transportation, and agricultural sectors, as well as land use change (EPA 2014a).

California is the 15th largest emitter of CO_2 in the world (California Air Resources Board [ARB] 2011). California produced 451.6 teragrams (Tg; or million metric tons) of CO_2 equivalents[2] (CO_2e) in 2010 (ARB 2013). The five major fuel consuming sectors contributing to CO_2 emissions from fossil fuel combustion are transportation, electricity generation, industrial, residential, and commercial. Combustion of fossil fuel in the transportation sector was the single largest source of California's GHG emissions, accounting for 38 percent of total GHG emissions in California. This sector was followed by the electric power sector (including both in-state and out-of-state sources) at 21 percent and the industrial sector at 19 percent (ARB 2013).

Methane is a highly potent GHG that results from off-gassing (the release of chemicals from nonmetallic substances under ambient or greater pressure conditions) largely associated with agricultural practices, landfills, and wetlands. CO_2 sinks, or reservoirs, include vegetative growth (which convert CO_2 to biomass) and the ocean, which absorbs CO_2 through photosynthesis by phytoplankton and dissolution, respectively, two of the most common processes of CO_2 sequestration (EPA 2014b).

Agriculture activities contributed 32.4 Tg CO_2e or 7 percent of California emissions. Of the 32.4 Tg CO_2e, agricultural emissions from crop growing and harvesting (including soil management and rice cultivation) accounted for 10 Tg CO_2e (ARB 2013). The remainder was mainly due to enteric fermentation for livestock and manure management (Figure 8-1).

The Project would involve changes to agriculture, wetlands, and riparian zones. The basic GHG emissions associated with these land use and management types is described below.

[2] CO_2e is a measurement used to account for the fact that different GHGs have different potential to retain infrared radiation in the atmosphere and contribute to the greenhouse effect. This potential, known as the global warming potential (GWP) of a GHG, is dependent on the lifetime, or persistence, of the gas molecule in the atmosphere. Expressing emissions in CO_2e takes the contributions of all GHG emissions to the greenhouse effect and converts them to a single unit equivalent to the effect that would occur if only CO_2 were being emitted.

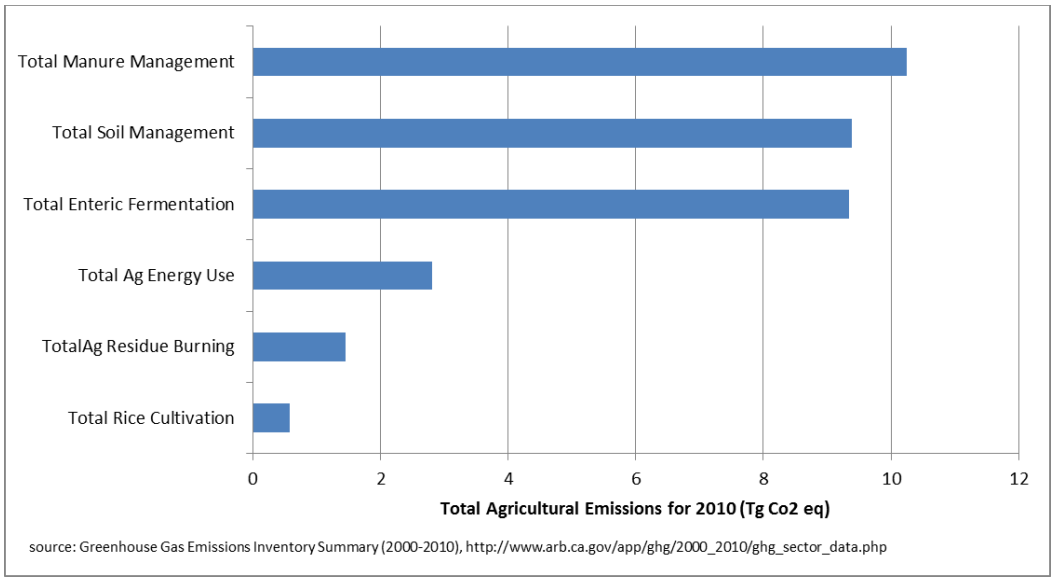

Figure 8-1.
2010 Estimated Breakdown of Agricultural GHG Sources for California

Agricultural soils emit N_2O, but act as net sinks for CO_2. In the United States, agricultural soils have accounted for approximately 75 percent of N_2O emissions and 5 percent of total emissions in 2012 (EPA 2014b). While total N_2O emissions are much lower than CO_2 emissions, N_2O is approximately 300 times more powerful than CO_2 at trapping heat in the atmosphere. Estimated emissions from agricultural soils were 306.6 Tg CO_2e in 2012 (EPA 2014b).

Nitrous oxide is produced naturally in soils through the microbial processes of nitrification and denitrification. A number of agricultural activities increase mineral Nitrogen (mineral N) availability in soils, thereby increasing the amount available for nitrification and denitrification, and ultimately the amount of N_2O emitted. These activities increase soil mineral N either directly or indirectly. Management practices that add or lead to greater release of direct emissions include fertilization, application of manure and other organic materials, deposition of manure on soils by domesticated animals in pastures, rangelands, and paddocks, production of N-fixing crops and forages, retention of crop residues, and drainage and cultivation of organic cropland soils (i.e., soils with a high organic matter content, for example peat soils as found in the Delta). Other agricultural soil management activities, including irrigation, drainage, tillage practices, and fallowing of land, can influence N mineralization in soils and thereby affect direct emissions. Mineral N is also made available in soils through decomposition of soil organic matter and plant litter, as well as asymbiotic fixation of N from the atmosphere, and these processes are influenced by agricultural management through impacts on moisture and temperature regimes in soils. Indirect emissions of N_2O occur through two pathways: (1) volatilization and subsequent atmospheric deposition of applied/mineralized N, and (2) surface runoff and leaching of applied/mineralized N into groundwater and surface water (Massy and Ulmer 2010, EPA 2014b).

Soils contain both organic and inorganic forms of carbon. Soil organic carbon stocks are the main source and sink for atmospheric CO_2 in most soils and account for about 1 percent of the total net CO_2 flux in the United States (EPA 2014b). In agricultural soils, mineral and organic soils sequester approximately four times as much carbon as is emitted from these soils through liming and urea fertilization. Net carbon uptake is largely due to a reduction in summer fallow areas in semi-arid areas, the adoption of conservation tillage practices, and application of organic fertilizers to agriculture lands. Although CO_2 is sequestered in agricultural soils, the amount of CO_2 uptake is small compared to CO_2e emitted as N_2O.

Wetlands are one of the largest natural sources of GHGs and are the major natural source of methane due to high rates of methanogenesis enabled by the presence of anaerobic soils (Altor and Mitsch 2006). Wetland plants uptake CO_2, which is converted to biomass and stored in organic soils. This storage of carbon in organic soils has resulted in a large carbon pool. The creation of wetlands can result in either a net increase or decrease in GHGs depending upon the time frame of interest and the characteristics of the wetland. On a mole for mole basis,[3] methane is a much more potent GHG than is CO_2. Over a 100-year time frame, it has about 21 times as much global warming potential (GWP)[4] as CO_2. Over shorter time frames, it has an even greater GWP due to the lifetime of methane in the atmosphere. Methane is oxidized to CO_2 and carbon monoxide (CO) in about 10 years. So in general, a wetland can initially be considered a net GHG source and over time as more carbon is sequestered in organic soils a net GHG sink. The time required for the wetland to change from a net source to a net sink depends upon the ratio of carbon emitted as methane to carbon sequestered as CO_2. Whiting and Chanton (2001) studied the rate of sequestration of carbon and the rate of methane emission from several different types of wetlands. Their data showed that the wetlands they studied would be net sources for 20 years, some sources and some sinks after 100 years, and all sinks after 500 years. However, estimates of the GWP have increased since their study, so their results can be considered as low estimates.

Riparian zones that are oxic (contain oxygen) are net sinks for methane and sources of N_2O. Aerated soil contains methanotrophic bacteria that use methane as their carbon source. N_2O is produced in riparian soils primarily through decomposition of soil organic matter and plant litter, as well as asymbiotic fixation of N from the atmosphere. Tanzosh (2005) studied two watersheds in Ohio, each of which contained upland agricultural land, riparian grassland and riparian forest. Her results showed that the riparian grassland had the greatest GWP, but was only slightly more than the upland sites. The forested areas had the smallest GWP. However, carbon can be sequestered in riparian soils if the conditions are advantageous. This would occur when the conditions are right for the formation of soils that incorporate carbon into the soil matrix so it is available for plant use. If the rate of plant growth is large it is possible for the sequestration to exceed the carbon emitted as GHGs.

[3] A mole is a unit of measurement used to express an amount of chemical substance (i.e., 6.022×10^{23} molecules).

[4] GWP is the potential to retain infrared radiation in the atmosphere and contribute to the greenhouse effect over a specified time period (e.g., 100 years).

8.1.2 Temperature, Precipitation, and Runoff

Historical Climate

The historical climate of the Central Valley is characterized by hot, dry summers and cool, damp winters. Summer daytime temperatures can reach 90 degrees Fahrenheit (°F) with occasional heat waves bringing temperatures exceeding 115°F. The majority of precipitation occurs from mid-autumn to mid-spring. In winter, temperatures below freezing may occur, but snow is rare in the valley lowlands and foothills. During the growing season, relative humidity is characteristically low; in the winter, humidity is usually moderate to high, and ground fog may form.

The inter-annual variability of the Central Valley climate is strongly influenced by conditions occurring in the Pacific Ocean, including the El Nino Southern Oscillation and the existence of a semi-permanent high-pressure area in the northern Pacific Ocean. Although variable, the average mean-annual temperature has increased by approximately 2°F during the course of the 20th century for both the Sacramento River Basin and the San Joaquin River Basin.

Streamflow in the Sacramento River and San Joaquin River basins has also varied considerably from year to year and is varied geographically. Runoff is generally greater during the winter and spring months, with winter runoff generally originating from rainfall-runoff events and spring to early summer runoff generally supported by snowmelt from the Sierra Nevada. Historical changes in climate have resulted in declining spring runoff and a corresponding increase in winter runoff.

Future Projections

Climate change is a complex phenomenon that results in changes to several different aspects of the climate. One of the major impacts of climate change is an increase in average temperature. The average air temperature in the Project area and vicinity is projected to increase from almost 4°F to over 6°F by the end of the century (2070-2090 period) compared to the baseline conditions (1961-1990) (Cal-Adapt 2012). This increase in temperature is expected to result in changes in precipitation patterns. Depending upon the assumptions and climate models used for a particular study, both wetter and drier conditions have been projected (Brekke et al. 2004, Pacific Northwest Research Station 2005, PRBO Conservation Science 2011). Overall, Cal-Adapt projects a possible decrease in the average annual precipitation of 0 to 2 inches in the Project area and vicinity. Climate change may result in changes to the pattern of snowfall in the mountains above Friant Dam, leading to less overall water storage in the mountains. Cal-Adapt projects that the April snow water equivalent in the mountains above Friant Dam could decrease by 80 to 90 percent in the lower elevations and 30 to 40 percent at the upper elevations by the year 2100 (Cal-Adapt 2012b). This would result in less spring and summer runoff into Millerton Reservoir than at present.

Climate modeling groups have produced hundreds of simulations of past and future climates for the IPCC Fourth Assessment Report. The World Climate Research Programme Working Group on Coupled Modelling helped to coordinate these activities through the Coupled Model Intercomparison Project Phase 3. These model results were

organized into a website hosted by the Lawrence Livermore National Laboratory (LLNL) and others (LLNL 2013). The U.S. Department of the Interior, Bureau of Reclamation (Reclamation), working with others, generated gridded (1/8 degree [°] by 1/8°, latitude by longitude) climate projections using these data. These projections were developed through support from the Reclamation WaterSMART Basin Studies Program as part of the West-Wide Climate Risk Assessments activity (Reclamation 2011). These projections consist of 16 different Global Climate Models and three different CO_2 emission scenarios from the IPCC Fourth Assessment Report. For several of the projections, results were provided using different initial conditions for a total of 112 different projections (the results of climate projection modeling are sensitive to the initial conditions used in the models). From these climate projections potential changes in hydrology were computed for three future decades: 2020s (water years 2020 to 2029), 2050s (water years 2050 to 2059) and 2070 (water years 2070 to 2079) from the reference 1990s' decade (water years 1990 to 1999). The reference 1990s is from the ensemble of simulated historical hydroclimates, not from the observed 1990s data.

Future Runoff Projections

The gridded model output was used to estimate runoff from watersheds covering the major Reclamation basins and the Western United States (Reclamation 2011). Runoff results for the San Joaquin River at Friant Dam (Figure 8-2) show the change in total annual runoff into Millerton Reservoir relative to the total annual runoff in the 1990 decade. For the period 2010 to 2050 the total annual runoff is expected to decrease to about 90 to 95 percent of the 1990 decade. By the end of the century the total annual runoff is expected to decrease to between 75 to 80 percent of the 1990 decade. This analysis is based on the median projection from 112 model outputs (Reclamation 2011). It should be noted that the variability between model results is large with the coefficient of variability (standard deviation divided by the mean) equal to about 1.

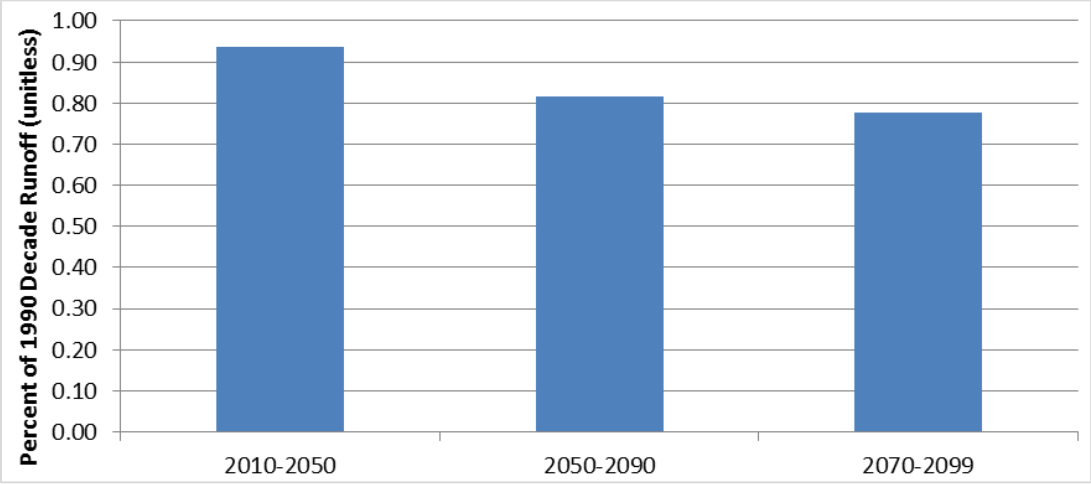

Figure 8-2.
Change in the Total Runoff into Millerton Reservoir Relative to 1990 Decade

In addition to the decrease in runoff, the timing of the runoff is expected to change. Figure 8-3 shows ensemble-median mean-monthly values (heavy lines) for the 1990s, 2020s, 2050s, and 2070s for the San Joaquin River at Friant Dam, and the decadal-spread of mean-monthly runoff for the 1990s (grey shaded area) and 2070s (magenta shaded area) where spread is bound by the ensemble's 5th to 95th percentile values for each month (the purple shaded area is where the spreads overlap). The spread shown in the figure does not represent the expected range in flows, but the uncertainty in the future projections. In general, in the future there would be more runoff in winter/spring (January to April) and less runoff in the summer (May to July). The change in inflows is small in the 2020 decade; the 2020 values are within the uncertainty of the 1990 and 2020 decades' data, so little effect would be expected on the timing of inflows during that period. By the 2070 decade, the results show a noticeable drop in runoff during the spring/summer period though there is a large uncertainty in the model predictions. Regardless, the operation of the larger dams in the San Joaquin River system, primarily Friant Dam, would determine the timing of summer flows in the San Joaquin River.

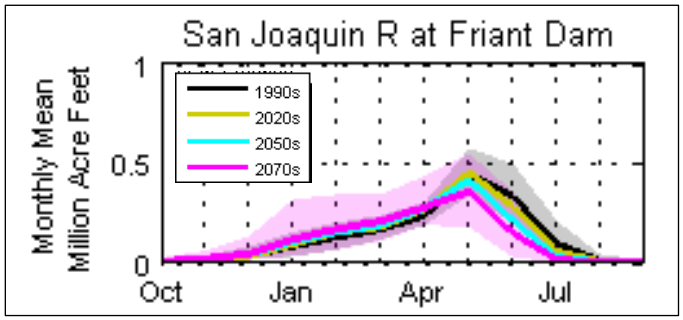

Figure 8-3.
Changes in Runoff to Friant Dam from 1990s to 2070s based on Analysis of 112 Different Combinations of Global Climate Models and Emission Scenarios

Future Water Temperature

The increase in air temperature due to climate change has the potential to increase water temperatures in the San Joaquin River. An estimate of the scale of the effect of increased air temperature on water temperature was made by estimating the equilibrium temperature of the water with and without climate change. The equilibrium temperature is the water temperature where there is zero net heat exchange between the water and its surroundings. If the meteorology conditions were constant for several days to a week or so, depending upon the depth of water and the meteorology, the river water temperature would eventually equal the equilibrium temperature. However, since the meteorology conditions are never constant, the water temperature tends to "chase" the equilibrium temperature, lagging its increase in the spring in summer as solar radiation and air temperature increases and in the fall and winter when solar radiation and air temperature decreases. The calculation of equilibrium temperature follows the procedures described in Bogan, Mohseni, and Stefan (2003) with the following assumptions:

- Cloud cover is zero.
- Wind speed is zero.
- No precipitation.
- Surface albedo = 0.31.

Figure 8-4 compares the equilibrium water temperature to measured water temperature in the San Joaquin River below the Chowchilla Bypass. Solar radiation and air temperature data for the calculation were obtained for the California Irrigation Management Information System (CIMIS) Station 7, Firebaugh/Telles (CIMIS 2013). Observed water temperature data were obtained for the California Data Exchange Center [CDEC] database for Station San Joaquin River below Bifurcation (SJB) (CDEC 2013). The observed water temperature lags the equilibrium temperature by 10 to 15 degrees centigrade (°C) (18 to 27°F), but can be almost 30°C (54°F) lower in the summer.

Figure 8-5 shows the increase in equilibrium water temperature, using the same 2012 data described above, for the cases of a 2, 4 and 6°C (3.6, 7.2 and 10.8°F) increase in air temperature.

In the winter the increase in equilibrium temperature is less than the increase in air temperature. However, in the summer the increase is greater indicating that summer water temperatures would be affected more than winter/spring water temperatures. This is driven by the increase in atmospheric long-wave radiation. Atmospheric radiation is modeled as a function of air temperature to the fourth power so increases in high air temperatures have a greater effect on water temperatures than increases in lower air temperatures. Note, that the actual increase in water temperature will likely be less than the increase in equilibrium temperatures shown in Figure 8-5 as the results shown in Figure 8-5 do not include cloud cover and wind speed which has the effect of lowering temperatures. Regardless, there is likely to be an increase in water temperature in Reach 2B due to climate change. The relative (to air temperature) increase will be small in the spring, but larger in the summer.

As the existing climate throughout California changes over time, the ranges of various plant, fish, and wildlife species could shift or be reduced, depending on the favored temperature and/or moisture regimes of each species. In the Project area, changes in vegetation, fish, and wildlife would depend, in part, upon water temperature, the amount of available water, and the available seed bank.

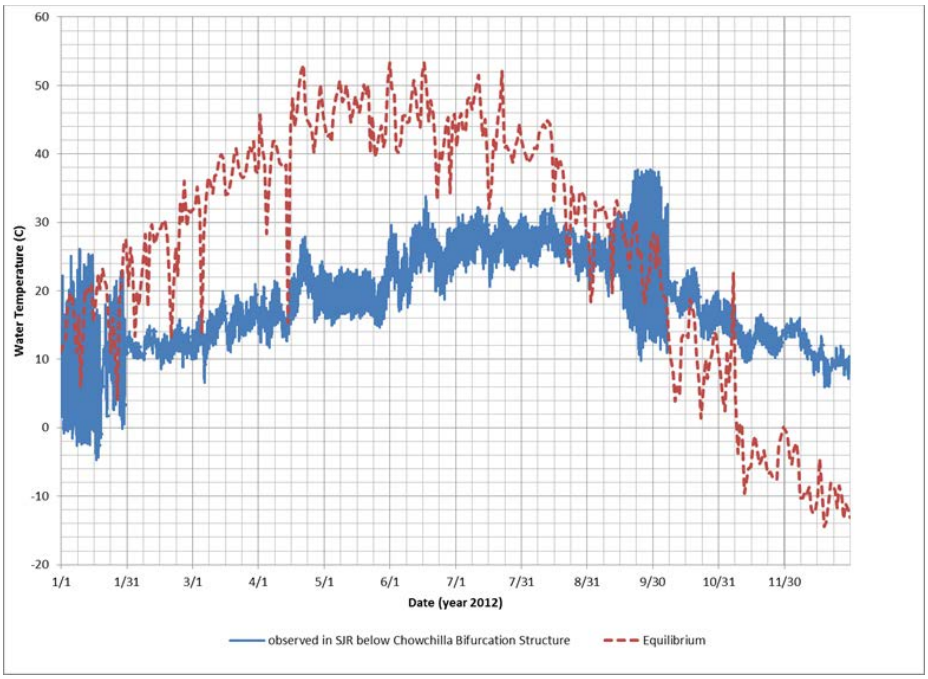

Figure 8-4.
Comparison between Measured and Equilibrium Water Temperatures in Reach 2B for Calendar Year 2012

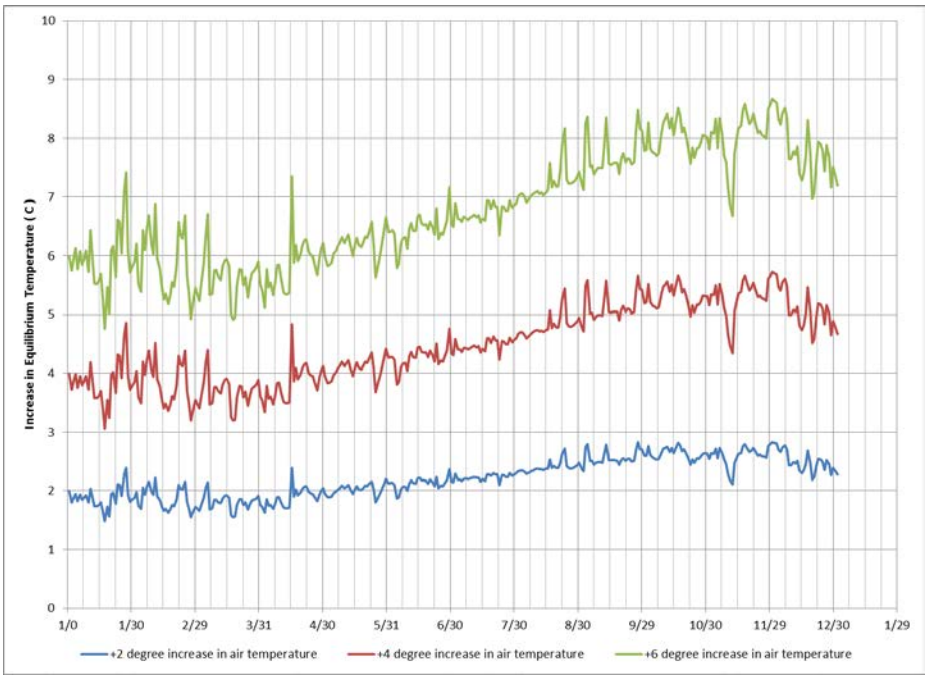

Figure 8-5.
Increase in Equilibrium Water Temperature for a Range of Increases in Air Temperature

8.2 Regulatory Setting

8.2.1 Federal

Climate change and GHG emission reductions are a concern at the Federal level. Laws and regulations, as well as plans and policies, address global climate change issues. This section summarizes key Federal regulations relevant to the Project.

EPA Endangerment and Cause and Contribute Findings

On December 7, 2009, the EPA Administrator signed two distinct findings regarding GHGs under Section 202(a) of the Federal Clean Air Act (CAA):

- *Endangerment Finding:* the current and projected concentrations of the six key GHGs— CO_2, methane, N_2O, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride—in the atmosphere threaten the public health and welfare of current and future generations.
- *Cause or Contribute Finding:* the combined emissions of these well-mixed GHGs from new motor vehicles and new motor vehicle engines contribute to the GHG pollution, which threatens public health and welfare.

This endangerment finding was challenged and in *Massachusetts v. U.S. Environmental Protection Agency, et al*., 549 U.S. 497, the United States Supreme Court ruled that GHG does fit within the CAA's definition of a pollutant, and that the EPA has the authority to regulate GHG. Therefore, the endangerment finding by the EPA stands.

EPA Mandatory Greenhouse Gas Reporting Rule

On September 22, 2009, the EPA released its final GHG Reporting Rule. The reporting rule is a response to the Federal fiscal year 2008 Consolidated Appropriations Act (H.R. 2764; Public Law 110-161), that required the EPA to develop "… mandatory reporting of GHGs above appropriate thresholds in all sectors of the economy…." The reporting rule applies to most entities that emit 25,000 metric tons of CO_2e ($MTCO_2e$) or more per year. Since 2010, facility owners have been required to submit an annual GHG emissions report with detailed calculations of facility GHG emissions. The reporting rule also mandates recordkeeping and administrative requirements in order for the EPA to verify annual GHG emissions reports.

Council on Environmental Quality Guidance

On February 18, 2010, the White House Council on Environmental Quality (CEQ) released draft guidance regarding the consideration of GHG in National Environmental Policy Act (NEPA) documents for Federal actions. The draft guidelines include a presumptive threshold of 25,000 $MTCO_2e$ emissions from a proposed action to trigger a quantitative analysis. The CEQ has not established when GHG emissions are "significant" for NEPA purposes; rather, it poses the question to the public (CEQ 2010).

Executive Order 13514

Executive Order (EO) 13514, *Federal Leadership in Environmental, Energy, and Economic Performance*, signed on October 5, 2009, establishes "an integrated strategy towards sustainability in the Federal Government and makes reduction of GHG emissions

a priority for Federal agencies." Federal fleets would reach this vision by reducing fleet GHG emissions through reduced petroleum consumption. In March 2011, the CEQ issued instructions for implementing climate change adaptation planning in accordance with EO 13514.

Department of the Interior Climate Change Policy

The Department of the Interior has established a climate change impacts policy, which provides the following guidance:

- Ensure that climate adaptation plans are grounded in the best available science and understanding of climate change risks, impacts, and vulnerabilities, incorporating traditional knowledge where available.
- Consider climate change when developing or revising management plans, setting priorities for scientific research and assessments, and making major investment decisions.
- Use well-defined and established approaches, as appropriate, for managing through uncertainty, including: (1) vulnerability assessments, (2) scenario planning, (3) adaptive management, and (4) other risk management or structured decision making approaches.

8.2.2 State of California

Various statewide initiatives to reduce the State's contribution to GHG emissions have raised awareness that, even though the various contributors to and consequences of global climate change are not yet fully understood, global climate change is under way, and there is a real potential for severe adverse environmental, social, and economic effects in the long term.

Executive Order S-3-05

Executive Order (EO) S-3-05, which was signed by Governor Schwarzenegger in 2005, proclaims that California is vulnerable to the impacts of climate change. It declares that increased temperatures could reduce the Sierra's snowpack, further exacerbate California's air quality problems, and potentially cause a rise in sea levels. To combat those concerns, the EO established total GHG emission targets. Specifically, emissions are to be reduced to the 2000 level by 2010, the 1990 level by 2020, and to 80 percent below the 1990 level by 2050.

The EO directed the Secretary of the California Environmental Protection Agency (Cal/EPA) to coordinate a multi-agency effort to reduce GHG emissions to the target levels. The Secretary will also submit biannual reports to the governor and State legislature describing: progress made toward reaching the emission targets, impacts of global warming on California's resources, and mitigation and adaptation plans to combat these impacts. To comply with the EO, the Secretary of the Cal/EPA created the California Climate Action Team made up of members from various State agencies and commissions. The California Climate Action Team released its first report in March 2006. The report proposed to achieve the targets by building on voluntary actions of California businesses, local governments, and the community, as well as through State

incentive and regulatory programs. The latest of these reports, *Climate Action Team Report to Governor Schwarzenegger and the California Legislature*, was published in December 2010 (Cal/EPA 2010).

As a result of the thorough scientific analysis collected in these biennial reports, the comprehensive Climate Adaptation Strategy was released in December 2009 after extensive interagency coordination and stakeholder input. The California Natural Resources Agency (CNRA), in coordination with other State agencies, has updated the 2009 California Climate Adaptation Strategy. The *Safeguarding California Plan* (CNRA 2014) augments previously identified strategies in light of advances in climate science and risk management options (see http://resources.ca.gov/climate/safeguarding/).

Executive Order B-30-15

EO B-30-15 was signed by Governor Brown in April 2015. This EO establishes a California greenhouse gas reduction target of 40 percent below 1990 levels by 2030. This target is in line with levels needed in the U.S. to limit global warming below 2 degrees Celsius and will also facilitate reaching the ultimate goal of reducing emissions 80 percent under 1990 levels by 2050. The EO also specifically addresses the need for climate adaptation and directs State government to:

- Incorporate climate change impacts into the State's Five-Year Infrastructure Plan.
- Update the Safeguarding California Plan - the state climate adaption strategy - to identify how climate change will affect California infrastructure and industry and what actions the state can take to reduce the risks posed by climate change.
- Factor climate change into State agencies' planning and investment decisions.
- Implement measures under existing agency and departmental authority to reduce greenhouse gas emissions.

The Global Warming Solutions Act of 2006

In 2006, California passed the California Global Warming Solutions Act of 2006 (Assembly Bill [AB] 32; Health & Saf. Code, § 38500 et seq., or AB 32). AB 32 further details and puts into law the mid-term GHG emissions reduction target established in EO S-3-05 to reduce statewide GHG emissions to 1990 levels by 2020. AB 32 also identifies the ARB as the State agency responsible for the design and implementation of emissions limits, regulations, and other measures to meet the target.

The statute presents the schedule for each step of the regulatory development and implementation process. In accordance with the AB 32 statutory requirements, the ARB published a list of early-action GHG emissions reduction measures by June 30, 2007.

Prior to January 1, 2008, the ARB also identified the current level of GHG emissions by requiring statewide reporting and verification of GHG emissions from emitters and identified the 1990 levels of California GHG emissions. By January 1, 2010, the ARB adopted regulations to implement the early-action measures.

In December 2007, the ARB approved the 2020 emissions limit (1990 emissions level) of 427 million $MTCO_2e$ of GHGs. The 2020 target requires the reduction of 80 million $MTCO_2e$, or approximately 16 percent below the State's projected "business-as-usual" 2020 emissions of 507 million $MTCO_2e$.

Also in December 2007, the ARB adopted mandatory reporting and verification regulations pursuant to AB 32. The regulations became effective January 1, 2009, with the first reports covering 2008 emissions; the regulations were updated in 2012, and the updates became effective in 2013. The mandatory reporting regulations require reporting for major facilities that generate more than 10,000 $MTCO_{2e}$ per year. The ARB has met all of the statutorily mandated deadlines for promulgation and adoption of regulations.

Scoping Plan

On December 11, 2008, pursuant to AB 32, the ARB adopted the Climate Change Scoping Plan (Scoping Plan). This plan outlines how emissions reductions would be achieved from significant sources of GHGs via regulations, market mechanisms, and other actions. Six key elements, outlined in the Scoping Plan, are identified below to achieve emissions reduction targets:

- Expanding and strengthening existing energy efficiency programs, including building and appliance standards.
- Achieving a statewide renewable energy goal of 33 percent.
- Developing a California cap-and-trade program that links with other Western Climate Initiative partner programs to create a regional market system.
- Establishing targets for transportation-related GHG emissions for regions throughout California, and pursuing policies and incentives to achieve those targets.
- Adopting and implementing measures pursuant to existing State laws and policies, including California's clean car standards, goods movement measures, and the Low Carbon Fuel Standard.
- Creating targeted fees, including a public goods charge on water use, fees on high global warming potential gases, and a fee to fund the administrative costs of the State's long-term commitment to AB 32 implementation.

The Scoping Plan also recommended 39 measures that were developed to reduce GHG emissions from key sources and activities while improving public health, promoting a cleaner environment, preserving our natural resources, and ensuring that the impacts of the reductions are equitable and do not disproportionately impact low-income and minority communities. These measures also put the State on a path to meet the long-term 2050 goal of reducing California's GHG emissions to 80 percent below 1990 levels.

To comply with AB 32 requirements for scoping plan updates, the ARB adopted the First Update to the AB 32 Scoping Plan in May 2014. The First Update defines the ARB's climate change priorities for the next 5 years and evaluates the alignment of long-term GHG reduction strategies with other State policy priorities areas.

8.2.3 Regional and Local

San Joaquin Valley Air Pollution Control District Guidance and Policy

The San Joaquin Air Pollution Control District (SJVAPCD) has established policies and guidance relating to GHG emissions from projects undergoing the California Environmental Quality Act Process (CEQA) process. On December 17, 2009, the SJVAPCD adopted the *Guidance for Valley Land-use Agencies in Addressing GHG Emission Impacts for New Projects under CEQA* to assist other lead agencies in establishing their own process for determining significance of project GHG impacts. The SJVAPCD also adopted the *District Policy – Addressing GHG Emission Impacts for Stationary Source Projects under CEQA when Serving as the Lead Agency* for its own use when serving as a lead agency. In support of the guidance document and policy, SJVAPCD also prepared a staff report, *Climate Change Action Plan: Addressing Greenhouse Gas Emissions under the California Environmental Quality Act*, which evaluates different approaches to assessing significance for GHG emission impacts (SJVAPCD 2009).

The guidance and policy rely on the use of performance based standards, otherwise known as Best Performance Standards, to assess significance of project specific GHG emissions on global climate change during the environmental review process, as required by CEQA. Lead agencies adopting this guidance as policy for addressing GHG impacts under CEQA would require that all projects with increased GHG emissions implement the Best Performance Standards, or otherwise demonstrate that project GHG emissions have been reduced by at least 29 percent from business-as-usual, to determine that a project would have a less than significant impact. The SJVAPCD has not established Best Performance Standards for construction or restoration projects.

8.3 Environmental Consequences and Mitigation Measures

8.3.1 Impact Assessment Methodology

This section focuses on the contribution of the Project alternatives to the buildup of GHGs in the atmosphere, which has been shown to contribute to climate change. It is unlikely that any single project by itself could have a significant impact on the environment with respect to GHGs. However, the cumulative effect of human activities has been clearly linked to quantifiable changes in the composition of the atmosphere, which has in turn been shown to be the main cause of global climate change.

The Project would emit GHGs from off-road construction equipment and worker vehicle trips associated with construction-related activities. Project operations would also result in GHG emissions, but only from worker vehicle trips to provide maintenance and operational support for the Project. The principal GHGs associated with the Project would be CO_2 and methane. The GHG emissions were quantified using the *Informal Guidance for California Department of Water Resources (DWR) Grantees: GHG Assessment for CEQA Purpose*.

Direct GHG emissions from construction equipment exhaust were estimated using the same models used for estimating criteria pollutant emissions (i.e., Roadway Construction Emissions Model [RoadMod], which incorporates ARB's In-Use Offroad 2011 Emission Inventory Model for off-road equipment and Emission Factors Modeling Software [EMFAC] for on-road mobile sources). These models only provide emission factors for CO_2 and methane. CO_2e emissions were estimated by multiplying the CO_2 and methane emission by their respective GWP factors. N_2O emissions are small and their exclusion has no material impact on the overall calculation of GHG emissions.

Indirect GHG emissions associated with electricity and water use are not quantified as these would be minimal compared to the amount of emissions from offroad equipment and onroad vehicles. At this time, there is not anticipated to be any substantial use of equipment powered by electricity for construction or operations.

GHG emissions associated with changes in carbon sequestration due to land use changes have been addressed in a qualitative manner for wetlands, discussing some of the anticipated outcomes based on evolving scientific studies, and a quantitative manner for growth of riparian habitat, based on ARB's estimates for carbon sequestration.

8.3.2 Significance Criteria

GHG Construction Threshold

As discussed previously, the SJVAPCD has provided guidance for evaluating significance of GHG emissions that is intended to assist lead agencies in addressing GHG impacts for CEQA purposes, but the determination of significant impacts are ultimately within the purview of the lead agency. The SJVAPCD guidance on assessing significance relies on Best Performance Standards and demonstration of GHG reductions compared to business as usual conditions. Best Performance Standards have not been established for construction projects.

As lead agency under CEQA, the CSLC evaluates projects on a case-by-case basis when determining whether or not project GHG impacts are significant. For this project, the CSLC recommends that construction GHG emissions be amortized over the life of the project (assumed to be equivalent to the 49-year lease period), and compared to a quantitative significance threshold of 10,000 $MTCO_2e$ per year to determine the significance of project GHG impacts from construction. The CSLC developed this recommendation based on their consideration of several California Air Quality Management District (AQMD) and Air Pollution Control District (APCD) significance thresholds for large construction projects.[5]

For NEPA effects, the CEQ quantitative analysis trigger level of 25,000 $MTCO_2e$ per year is a useful indicator for long-term actions with annual emissions, but a methodology

[5] There is no specific value used for a significance threshold among different air districts. For example, the South Coast Air Quality Management District uses the 10,000 $MTCO_{2e}$ per year threshold for significance, but the SJVAPCD only specifies a zero equivalency value (which is much smaller). Also note that some agencies use their own values, for example the DWR climate action plan specifies a 25,000 $MTCO_{2e}$ per year threshold for construction.

to evaluate short-term construction emissions is not provided. Therefore, the methodology and significance threshold used to determine CEQA significance of construction GHG emissions is also used to determine NEPA effects in this analysis.

GHG Operational Threshold

The SJVAPCD guidance on assessing significance relies on Best Performance Standards and demonstration of GHG reductions compared to business as usual conditions. Best Performance Standards have not been established for operations and maintenance of restoration projects.

The SJVAPCD has adopted a Zero Equivalency Policy for Greenhouse Gases, which establishes a level below which GHG emissions are considered equivalent to zero for SJVAPCD permitting purposes. GHG emissions of 230 $MTCO_2e$ per year or less are considered to be zero for SJVAPCD permitting purposes. The SJVAPCD has not adopted this level as a significance threshold, but rather as an approved GHG emissions level that would be considered equivalent to zero.

To determine NEPA effects associated with project operations, the annual operational emissions will be compared to the CEQ quantitative analysis trigger level of 25,000 $MTCO_2e$ per year.

8.3.3 Impacts and Mitigation Measures

This section provides a Project-level evaluation of direct and indirect effects of the Project Alternatives on climate change and GHG emissions. It includes analyses of potential effects relative to No-Action conditions in accordance with NEPA and potential impacts compared to existing conditions to meet CEQA requirements. The analysis is organized by Project alternative with specific impact topics numbered sequentially under each alternative. With respect to climate change and GHG emissions, the environmental impact issues and concerns are:

1. Impacts from GHG Emissions Associated with Project Construction.
2. Impacts from GHG Emissions Associated with Project Operation.
3. Changes in Land Use that Result in a Net Change in GHG Emissions.

The following analysis considers the Project's contribution to climate change and GHG emissions in the context of the cumulative condition. Other climate change and GHG emissions-related issues covered in the Program Environmental Impact Statement/Report (PEIS/R) (SJRRP 2011) are not covered here because they are programmatic in nature and/or are not relevant to the Project area.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. However, other proposed actions under the SJRRP would be implemented, including habitat restoration in other reaches, augmentation of river flows, and reintroduction of salmon. Without the Project in Reach 2B, however, these Program-level activities would not achieve Settlement goals. This section describes the impacts of the No-Action

Alternative. The analysis is a comparison to existing conditions, and no mitigation is required for No-Action.

Impact CC-1 (No-Action Alternative): *Impacts from GHG Emissions Associated with Project Construction*. Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed. Therefore there would be no GHG emissions associated with construction of the Project. There would be **no impact**.

Impact CC-2 (No-Action Alternative): *Impacts from GHG Emissions Associated with Project Operation*. Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed. Therefore there would be no GHG emissions associated with operation of the Project. There would be **no impact**.

Impact CC-3 (No-Action Alternative): *Changes in Land Use that Result in a Net Change in GHG Emissions*. Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed. There would be no Project-related land use changes. Therefore, there would be **no impact.**

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

Alternative A would include construction of Project facilities including a Compact Bypass channel, a levee system with a narrow floodplain encompassing the river channel, and the South Canal. Other key features include construction of the Mendota Pool dike (separating the San Joaquin River and Mendota Pool), a fish barrier below Mendota Dam, and the South Canal bifurcation structure with fish passage facility and fish screens, modification of the San Mateo Avenue crossing, and the removal of the San Joaquin River control structure of the Chowchilla Bifurcation Structure. Construction activity is expected to occur intermittently over an approximate 132-month timeframe.

Impact CC-1 (Alternative A): *Impacts from GHG Emissions Associated with Project Construction*. Compared to No-Action, Alternative A would directly emit GHG emissions as a result of construction activities associated with the Project. These direct emissions from offroad construction equipment and onroad vehicles were quantified. (Full details of the methodology used to quantify emissions are contained in Chapter 4.0, "Air Quality." The construction offroad equipment schedule was provided by DWR.) GHG emissions associated with the operation of the equipment were estimated using statewide emission factors. Emissions associated with hauling of material to the Project area were estimated using EMFAC. Table 8-1 shows the GHG emissions associated with construction under each of the Action Alternatives.

As shown in Table 8-1, the amortized GHG emissions associated with construction of the Project is below the significance threshold of 10,000 $MTCO_2e$ per year under each alternative.

Furthermore, implementation of Mitigation Measures AQ-1A and AQ-1B to reduce criteria pollutant emissions from construction equipment and hauling trucks, respectively,

could result in GHG emission co-benefits and further reduce GHG emissions below significance thresholds. The potential magnitude of these co-benefits would be highly depend on the specific measures applied, as well as the extent to which these measures are applied (e.g., the percentage of the equipment and vehicle fleet mitigated). For example, the use of alternative fuels such as liquefied natural gas (LNG) or compressed natural gas (CNG) in material hauling trucks could reduce GHG emissions by up to 14 percent compared to diesel (see Tables 8-2 and 8-3). If this strategy was applied to all material hauling truck activity during construction, total GHG emissions could be reduced by up to approximately 65,200 $MTCO_2e$.

Implementation of Mitigation Measure AQ-1C may also result in GHG reduction co-benefits through the funding of emissions reductions programs through a voluntary emissions reduction agreement with SJVAPCD, although any potential GHG co-benefit would be dependent on the type of reduction programs funded. As such, there is not enough information to estimate the potential magnitude of GHG reduction co-benefits from implementing Mitigation Measure AQ-1C (if any).

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). Therefore, impacts from construction GHG emissions under Alternative A would be **less than significant**.

Table 8-1.
Total Project GHG Emissions

Year	$MTCO_2e$ per Year			
	Alternative A	**Alternative B**	**Alternative C**	**Alternative D**
Year 1	9,955	10,034	9,955	10,034
Year 2	30,390	30,518	30,390	30,518
Year 3	29,853	29,500	29,853	29,500
Year 4	25,611	27,837	25,611	27,837
Year 5	24,818	34,530	15,294	26,833
Year 6	72,809	67,323	47,319	47,319
Year 7	73,411	67,310	47,245	47,245
Year 8	73,097	66,997	46,587	46,587
Year 9	72,538	67,211	45,343	45,343
Year 10	65,690	49,541	NA	NA
Total $MTCO_2e$ Emissions	478,172	450,801	297,597	311,216
$MTCO_2e$ Emissions Amortized over Project Lifetime ($MTCO_2e$ per Year)	9,759	9,200	6,073	6,351

Notes: Amortized emissions assume a project life of 49 years (based on a 49-year lease period).
GHG = greenhouse gases
$MTCO_2e$ = metric tons of carbon dioxide equivalents

Table 8-2.
GHG Emissions from Fuel Combustion in Vehicles

Fuel Type	Fossil Carbon Intensity (gCO2e/MJ)	Energy Economy Ratio Adjustment for Vehicle Efficiencies	Adjusted Percent Reduction in Carbon Intensity Compared to Diesel
Diesel	74.9	1	--
Liquefied Natural Gas (LNG)	58.5	0.9	-13%
Compressed Natural Gas (CNG)	57.73	0.9	-14%

Source: California Air Resources Board 2009a, 2009b, 2012

GHG = greenhouse gases

gCO2e/MJ = grams of carbon dioxide equivalent per megajoule

Table 8-3.
Potential GHG Reductions from Use of CNG Trucks

Alternative	Total MTCO2e for Truck Trips	MTCO2e Reduction
Alternative A	454,395	-65,251
Alternative B	427,924	-61,449
Alternative C	275,441	-39,553
Alternative D	288,500	-41,428

Key:

CO2e = carbon dioxide equivalents

GHG = greenhouse gases

CNG = compressed natural gas

$MTCO_2e$ = metric tons of carbon dioxide equivalents

Impact CC-2 (Alternative A): ***Impacts from GHG emissions Associated with Project Operation*****.** Compared to the No-Action, Alternative A would incur GHG emissions associated with routine maintenance and operations of the Project upon completion. Table 8-4 shows the GHG emissions associated with the operational phases of the Action Alternatives. The operational GHG emissions are less than 10 $MTCO_2e$ per year. These emissions are a conservative estimate because the GHG emissions in future years would decrease due to improvements in emissions from onroad vehicles. The operational GHG emissions under Alternative A would be below the CEQ analysis trigger level of 25,000 $MTCO_2e$ per year.

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative A to the No-Action Alternative). The operational GHG emissions for Alternative A would be less than the zero equivalency level of 230 $MTCO_2e$ per year. Therefore, GHG emissions associated with Project operation for Alternative A would be **less than significant**.

Table 8-4.
Total Operational GHG Emissions

Alternative	$MTCO_2e$ per Year
Alternative A	5.21
Alternative B	5.21
Alternative C	5.21
Alternative D	5.02

Notes:
$MTCO_2e$ = metric tons of carbon dioxide equivalents
GHG = greenhouse gases

Impact CC-3 (Alternative A): ***Changes in Land Use that Result in a Net Change in GHG Emissions.*** Compared to the No-Action Alternative, the Project would create new floodplain areas within Reach 2B. In the area where levees are set back, there would be a change in land use from agriculture to riparian and wetland. Although wetlands can act as both a source and a sink for GHGs, growth of riparian habitat can increase carbon sequestration and reduce total GHG emissions.

Managed agriculture can be a major source of N_2O emissions, a highly potent GHG. Wetlands can be a source of methane, a potent GHG, but they also can sequester carbon. Whether wetlands are a net source or sink of GHG depends upon many factors including the time frame of interest and the characteristics of the wetland.

Altor and Mitsch (2006) looked at how intermittent versus continuous inundation of a wetland affected methane production. Their study concluded that intermittently flooded wetlands emitted significantly less methane than continuously flooded wetlands when the wetland was allowed to dry between flood events. Importantly, they observed that intermittently flooded wetlands emitted less methane when they were flooded then wetlands that are always flooded. In Reach 2B, most wetland areas are expected to be intermittently flooded and therefore may not be significant producers of methane. In addition, wetlands would become net sinks for carbon over the long term.

According to habitat restoration estimates, Alternative A could provide up to 100 acres of valley foothill riparian habitat, 200 acres of riparian scrub, and 390 acres of willow scrub in the Project area (SJRRP 2012, Attachment A). Assuming that new growth of riparian or shrub habitat can sequester approximately 44.3 $MTCO_2e$ per acre over the long-term (e.g., 100 years) (ARB 2014b), Alternative A could provide up to a 31,000 $MTCO_2e$ reduction. Wetland and riparian zones would likely result in a substantial decrease in GHG emissions relative to continued managed agriculture over the long term.

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). Therefore, compared to existing conditions, the Alternative A is expected to result in a **beneficial** effect.

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Alternative B would include construction of Project features including a Compact Bypass channel, a levee system with a wide, consensus-based floodplain encompassing the river channel, and the Compact Bypass Bifurcation Structure with fish passage facility and fish screens. Other key features include construction of a fish passage facility at the San Joaquin River control structure of Chowchilla Bifurcation Structure, the re-route of Drive 10 ½ (across the Compact Bypass bifurcation structure), and removal of the San Mateo Avenue crossing. Construction activity is expected to occur intermittently over an approximate 157-month timeframe.

Impact CC-1 (Alternative B): ***Impacts from GHG Emissions Associated with Project Construction*****.** Refer to Impact CC-1 (Alternative A). Potential construction impacts of Alternative B would be similar to the potential construction impacts of Alternative A except that the amortized GHG emissions associated with construction under Alternative B would be lower than Alternative A, as shown in Table 8-1. Construction GHG emissions under Alternative B would have a **less than significant** impact. Additionally, potential GHG emission reduction co-benefits from implementation of Mitigation Measures AQ-1A, AQ-1B, and AQ-1C would be similar to the potential co-benefits under Alternative A.

Impact CC-2 (Alternative B): ***Impacts from GHG emissions Associated with Project Operation*****.** Refer to Impact CC-2 (Alternative A). Potential operational impacts of Alternative B would be similar to the potential operational impacts of Alternative A. There would be a **less than significant** impact.

Impact CC-3 (Alternative B): ***Changes in Land Use that Result in a Net Change in GHG Emissions*****.** Refer to Impact CC-3 (Alternative A). Potential impacts of Alternative B would be similar to potential impacts of Alternative A. According to habitat restoration estimates, Alternative B could provide up to 340 acres of riparian scrub, 110 acres of valley foothill riparian habitat, and 500 acres of willow scrub in the Project area (SJRRP 2012, Attachment A). Assuming that new growth of riparian or shrub habitat can sequester approximately 44.3 MTCO2e per acre (ARB 2014b), Alternative B could provide up to a 42,000 MTCO2e reduction. This would result in a **beneficial** effect.

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Alternative C would include construction of Project features including Fresno Slough Dam, a levee system with a narrow floodplain encompassing the river channel, and the Short Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the Short Canal control structure and fish screen, the Chowchilla Bifurcation Structure fish passage facility, modification of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 133-month timeframe.

Impact CC-1 (Alternative C): ***Impacts from GHG Emissions Associated with Project Construction*****.** Refer to Impact CC-1 (Alternative A). Potential construction impacts of Alternative C would be similar to the potential construction impacts of Alternative A

except that the amortized GHG emissions associated with construction under Alternative C would be lower than Alternative A, as shown in Table 8-1. Construction GHG emissions under Alternative C would have a **less than significant** impact. Additionally, potential GHG emission reduction co-benefits from implementation of Mitigation Measures AQ-1A, AQ-1B, and AQ-1C would be similar to the potential co-benefits under Alternative A.

Impact CC-2 (Alternative C): *Impacts from GHG emissions Associated with Project Operation*. Refer to Impact CC-2 (Alternative A). Potential operational impacts of Alternative C would be similar to the potential operational impacts of Alternative A. There would be a **less than significant** impact.

Impact CC-3 (Alternative C): *Changes in Land Use that Result in a Net Change in GHG Emissions*. Refer to Impact CC-3 (Alternative A). Potential impacts of Alternative C would be similar to potential impacts of Alternative A. According to habitat restoration estimates, Alternative C could provide up to 200 acres of riparian scrub, 100 acres of valley foothill riparian habitat, and 470 acres of willow scrub in the Project area (SJRRP 2012, Attachment A). Assuming that new growth of riparian or shrub habitat can sequester approximately 44.3 MTCO2e per acre (ARB 2014b), Alternative C could provide up to a 34,000 MTCO2e reduction. This would result in a **beneficial** effect.

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Alternative D would include construction of Project features including Fresno Slough Dam, a levee system with a wide floodplain encompassing the river channel, and the North Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the North Canal bifurcation structure with fish passage facility and fish screens, removal of the San Joaquin River control structure of the Chowchilla Bifurcation Structure, removal of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 158-month timeframe.

Impact CC-1 (Alternative D): *Impacts from GHG Emissions Associated with Project Construction*. Refer to Impact CC-1 (Alternative A). Potential construction impacts of Alternative D would be similar to the potential construction impacts of Alternative A except that the amortized GHG emissions associated with construction under Alternative D would be lower than Alternative A, as shown in Table 8-1. Construction GHG emissions under Alternative D would have a **less than significant** impact. Additionally, potential GHG emission reduction co-benefits from implementation of Mitigation Measures AQ-1A, AQ-1B, and AQ-1C would be similar to the potential co-benefits under Alternative A.

Impact CC-2 (Alternative D): *Impacts from GHG emissions Associated with Project Operation*. Refer to Impact CC-2 (Alternative A). Potential impacts of Alternative D would be similar to potential impacts of Alternative A. There would be a **less than significant** impact.

Impact CC-3 (Alternative D): ***Changes in Land Use that Result in a Net Change in GHG Emissions*****.** Refer to Impact CC-3 (Alternative A). Potential impacts of Alternative D would be similar to potential impacts of Alternative A. According to habitat restoration estimates, Alternative D could provide up to 340 acres of riparian scrub, 110 acres of valley foothill riparian habitat, and 580 acres of willow scrub in the Project area (SJRRP 2012, Attachment A). Assuming that new growth of riparian or shrub habitat can sequester approximately 44.3 MTCO2e per acre (ARB 2014b), Alternative D could provide up to a 45,000 MTCO2e reduction. This would result in a **beneficial** effect.

9.0 Cultural Resources

This chapter describes the environmental and regulatory settings of cultural resources, as well as environmental consequences and mitigation, as they pertain to implementation of the Mendota Pool Bypass and Reach 2B Improvements Project (Project) alternatives. The discussion below includes descriptions of cultural resource conditions and the potential impacts of the Project alternatives on cultural resources for the area represented by the Project. The discussion in this section is supported by archaeological and historical architectural technical reports (Byrd et al. 2009) prepared for the Project, as well as for the Program Environmental Impact Statement/Report (PEIS/R) (SJRRP 2011), and the Native American ethnographic report (Davis-King 2009) prepared for the San Joaquin River Restoration Program (SJRRP). These reports are not publically available documents, as they contain confidential information on the location of sensitive cultural resources.

9.1 Environmental Setting

Cultural resources are defined as prehistoric and historic-era archaeological sites, Traditional Cultural Properties, Sites of Religious and Cultural Significance, and architectural properties (e.g., buildings, bridges, and structures). This definition includes historical properties as defined by the National Historic Preservation Act (NHPA). For the purposes of the discussion below, the term "Project area" refers to all areas that may be directly or indirectly affected by implementing Project actions. For the purposes of compliance with Section 106 of the NHPA, this area is identical to the "Area of Potential Effects" (APE).

A Programmatic Agreement (PA) is being developed among U.S. Department of the Interior, Bureau of Reclamation (Reclamation), the State Historic Preservation Office (SHPO) and consulting parties, including Native American Tribes, for compliance with Section 106 of the NHPA as it pertains to the Program. The PA would provide an overall framework for conducting the Section 106 process, including specific mitigation and review protocol, during the course of this Project as well as the entire SJRRP.

9.1.1 Regional Setting

The Project area lies within the central portion of the San Joaquin Valley, the southern extension of California's Great Central Valley. The source of the San Joaquin River is along the crest of the high Sierra Nevada, between Yosemite and Kings Canyon national parks. The river descends through high glacial valleys and then steep canyons before it enters the Central Valley north of Fresno. The San Joaquin River is the southernmost drainage that typically flows north to the Sacramento-San Joaquin Delta and San Francisco Bay. In wet years, the Kings River and even the Kern River overflow Tulare and Buena Vista lakes, respectively, and flow northward to join the San Joaquin.

Elevation within the Project area is approximately 150 feet near Mendota Pool where the San Joaquin River turns and beings flowing northward (Byrd et al. 2009).

Geology and Geomorphology

The central area and eastern side of the San Joaquin Valley is dominated by a complex intermingling of basin deposits that dominate the valley floor, and large alluvial fans that issue from the foothills of the Sierra Nevada and extend across the valley. This geomorphic contact is a geologically and seismically active area, and this activity has had a direct effect on surface geomorphology, deposition, and soils.

Due to the dynamic nature of California's landscape, archaeological sites deposited over approximately the last 13,500 years (roughly the time that humans are known to have lived in California) have been subject to numerous geomorphic processes. These processes have buried, destroyed, or left these sites intact on the surface. Within the San Joaquin Valley, geomorphic processes include response of alluvial fan deposition to changing climate, fluctuating river courses and related floodplain deposition, response of lakes (e.g., Tulare, Buena Vista) to climate, and response of the San Joaquin River to sea-level rise and upstream effects of the formation of the San Joaquin Delta. All of these factors have likely affected the differential preservation of archaeological sites on the surface, which hampers efforts to accurately assess the effects of the Project solely through archaeological reconnaissance surveys that are necessarily limited to investigation of the modern ground surface.

In general, most Pleistocene-age landforms have little potential for harboring buried archaeological resources, as they developed prior to human migration into North America (ca. 13,500 years before the present [B.P.]). However, Pleistocene surfaces buried below younger Holocene deposits do have a potential for containing archaeological deposits. Holocene alluvial deposits may contain buried soils (paleosols) that represent periods of landform stability before renewed deposition. The identification of paleosols within Holocene-age landforms is of particular interest because they represent formerly stable surfaces that have a potential for preserving archaeological deposits. See Section 18.1 on paleontological resources that may be present in the Project area, which are, conversely, primarily limited to Pleistocene or older landforms.

Vegetation

Extensive marshes once surrounded the lakes, sloughs, and rivers of the San Joaquin Valley. Before the historic period, their size varied seasonally and episodically, depending on larger environmental trends. Plants such as tules (*Scirpus lacustris*), growing as tall as 10 to 12 feet, covered the entire range of the wetlands. On drier ground, vegetation consisted of sagebrush (*Artemesia* species), greasewood (*Purshia tridentate*), saltbush (*Atriplex* species), and various bunchgrasses. Few trees inhabited the area except for along river channels, and included cottonwood (*Populus fremontii*), sycamore (*Platanus racemosa*), and willow (*Salix* species). Wildlife abounded in the lake and marshlands where large numbers of migratory ducks and geese joined thousands of year-round aquatic birds. Freshwater mussel (*Margaritifera margaritifera*), fish, and turtles were abundant, along with pronghorn antelope (*Antilocapra americana*), tule elk (*Cervus elaphus*), and winter herds of mule deer (*Odocoileus hemionus*). The area was also home

to plentiful numbers of rabbit (*Sylvilagus* species), black-tailed hare (*Lepus californicus*), and valley quail (*Lophortyx californica*) (Wallace 1978). The variety of wildlife in the San Joaquin Valley was typical for an area characterized by an arid to semi-arid climate, defined by hot summers and mild winters.

Cultural Setting

The following briefly discusses the archaeological record, the historical context, and the ethnographic context for the Project area. These contexts provide the basis for defining and ultimately evaluating any resources identified during the course of the investigation conducted for the purposes of this project.

Prehistoric Era

Prehistoric archaeological investigations have been limited within the San Joaquin River area of the Central Valley, and this area is considered by many to be one of the least understood regions in California with respect to prehistoric conditions (Moratto 1984, Riddell 2002, Rosenthal et al. 2007). As a result, archaeologists working in this area have been forced to borrow chronologies from nearby areas, particularly the foothills to the west (the eastern foothills of the Diablo Range) and to the east (the western slope of the Sierra Nevada) (Olsen and Payen 1969). These investigations of the western Sierra Nevada foothills have resulted in the formulation of local chronologies, notably the Chowchilla River/Buchanan Reservoir sequence.

Native American prehistoric occupation of the region began near the end of Pleistocene (circa 13,500 years ago) and continued until Spanish contact (in the late 1700s) (Rosenthal et al. 2007). Terminal Pleistocene (13,500 to 11,600 years ago) occupation in the region is represented by wide-ranging, mobile hunters and gatherers who periodically exploited large game. Throughout California, the prehistoric conditions of the Terminal Pleistocene are minimally represented and poorly understood. However, there is a probable Terminal Pleistocene site near Tulare Lake at the southern end of the Central Valley, and isolated artifacts dating to this era have been recovered within this area (Moratto 1984:81-82, Riddell and Olsen 1969).

Evidence of early Holocene (11,600 to 7,700 years ago) human settlement is only rarely encountered in the Central Valley (Rosenthal et al. 2007). Infrequent early Holocene sites in the foothills appear to have been seasonally occupied and include a robust ground stone assemblage focused on the processing of nuts. The lack of documented Central Valley early Holocene sites is undoubtedly due to sedimentation that has buried paleosurfaces of the time period (Rosenthal and Meyer 2004).

In the foothills, middle Holocene (7,700 to 3,800 years ago) sites are dominated by expedient cobble tools, likely used for various purposes including grinding, chopping, and pounding. Preserved plant remains from these sites are mainly represented by acorns and pine nuts. As with early Holocene sites, the relative lack of middle Holocene evidence in the Central Valley is due in large part to the archaeological record being buried by later sedimentation. Well-dated sites of this age in the Central Valley are typically discovered in buried contexts.

By 4,500 years ago, distinctive lowland and upland adaptive patterns emerged in the region (Rosenthal et al. 2007). Throughout the late Holocene (after 3,800 years ago) the Central Valley was characterized by a complex socioeconomic strategy focused on riverine and marsh resources and extremely elaborate material culture (Moratto 1984). Notable attributes included dart points, mortars and pestles; use of acorns and pine nuts; new fishing technologies and extensive exploitation of fisheries; basketry and cordage; ceramic items; diverse personal paraphernalia of stone, bone and shell; and large, formal cemetery areas.

Around 2,300 years ago, large populations began concentrating in major settlements along the San Joaquin River. Material culture included large dart points, mortars and pestles, milling stones, and bone spear points. Subsistence was concentrated on hunting and fishing and, based on secondary evidence, included hard seeds, with more limited use of acorns. Wide-ranging trade networks are documented and a non-egalitarian social organization and ascribed status may have emerged. With extended occupation at key settlements, large mounded villages were created. By approximately 1,000 years ago, population density had increased significantly, with noted developments in material culture including bow and arrow technology and new types of items of personal adornment.

Native Peoples at the Time of European Contact

At the time of contact with European settlers, the Project area was occupied by the Northern Valley Yokuts, who had lived in the region for some 4,500 years (Kroeber 1925; Latta 1977; Powers 1877; Wallace 1978). The Yokuts were hunter-gatherers who divided themselves into named tribes, each with a dialect, territory, and discrete settlements. Each tribe was politically autonomous and occupied a permanent area, usually on high ground along a major drainage course. The San Joaquin River and its main eastern tributaries formed the core of the Northern Valley Yokuts' homeland. Settlements west of the river tended to be in the foothills, concentrated along watercourses.

According to fragmentary information, the Yokuts exploited local subsistence resources from principal villages located on or near the San Joaquin River and other major streams (Cook 1955, 1960; Wallace 1978). Villages were composed of large, semisubterranean, round or oval dwellings. Some of the more major establishments also included larger communal dance houses. These villages were supported to a large extent by the riverine resources and by a variety of terrestrial plants, most importantly, oak trees for their acorns. Occupation was essentially sedentary, with dispersals occurring only seasonally for the acquisition of particular resources (Wallace 1978). Trade was focused along the river, where tule rafts were used for transportation. The Yokuts reportedly traded dogs to their Miwok neighbors in exchange for baskets and blankets. They acquired abalone and mussel shells from the coast and obsidian from the eastern slope of the Sierra Nevada.

Yokut populations at the time of Spanish contact have been estimated at about 41,000, with perhaps 5,000 living along the east side of the valley between the Merced and Kings rivers (Cook 1955). These numbers dropped drastically as native people here and throughout California were decimated by European and Euro-American diseases in the

early 19th century and by the tremendous influx of nonnative people during the local gold-mining period from the mid-19th and into the 20th centuries (Wallace 1978). Today there are still several bands of Yokuts Indians living in the San Joaquin Valley, though none are known to practice the traditional, pre-contact way of life.

Historic Era

For some time only sporadic interaction took place between Native Californians and Europeans (Beck and Haase 1974, Clough and Secrest 1984, Hayes 2007). The first Spanish expedition into the San Joaquin Valley was led by Pedro Fages in 1772 who sought a new route between San Diego and Monterey. In the 1820s, the objective of inland expeditions had changed from scouting new mission sites to punitive forays against the San Joaquin Valley Indians, both Yokuts and Miwoks. The Indians had engaged in sorties on missions, towns, and ranchos to steal livestock for food and transportation since the early 1800s. A cycle of raids and reprisals across the coastal mountains continued until American settlers took up permanent residence in the valley in the mid-1840s (Beck and Haase 1974, Broadbent 1974, Cook 1976).

While Mexican troops engaged in punitive expeditions against the San Joaquin Valley tribes, American trappers and explorers made their first journeys into the region. The first was Jedediah S. Smith in 1827. Other trappers from the Hudson's Bay Company passed through the Central Valley, as well as Kit Carson and Peter Ogden Skene. Perhaps the most famous explorer in the region at this time was John C. Fremont who was in the vicinity in 1844 (Clough and Secrest 1984, Fremont 1852, Smith 1977). Fremont also remarked on the abundance of wild horses on the west side of the San Joaquin River, and the difficulty of travel because of the swampy terrain and sloughs.

Two small Spanish settlements developed in the Project area near Fresno Slough in the early decades of the 1800s, called *Pueblo de Las Juntas* and *Rancho de los Californios* (California Ranch) (Clough and Secrest 1984, Wallace 1978). Officially sanctioned colonial settlement of the San Joaquin Valley began in the 1840s when the Mexican government issued its first land grants to individuals who petitioned for land. Two Mexican ranchos were successfully patented at the northwest end of the Project area on the west side of the San Joaquin River (Rancho Sanjon de Santa Rita and Orestimba Rancho), and a third claim in the foothills near Friant was rejected (Rancho Rio del San Joaquin).

In response to the gold rush, Americans quickly built a line of towns and roadside stations north and south across the 250-mile floor of the San Joaquin Valley, with Stockton as the central distributing point (Moehring 2004). The few towns in the Project area established during the second half of the nineteenth century all have their origins as favorable places to cross the San Joaquin River. A few were later sustained by agriculture or industry. For example, the settlement at the current site of Friant, on the San Joaquin River just below the Friant Dam, began as a ferry crossing on the San Joaquin River around 1854. Beginning in the early 20th century, gravel mining emerged as a major industry in the vicinity of Friant; several companies opened mines and the town benefitted economically. Boom times came with the construction of Friant Dam in the 1940s and gravel mines have continued to operate into recent years.

During the 1870s, the Central Pacific Railroad, and later the Southern Pacific Railroad, spawned a network of some 50 railroad stations, of which 24 became railroad town sites. About eight of these town sites became strategic trading centers stretching from Stockton south to Bakersfield; among them were towns in and near the Project area at Merced (1871), Sycamore (1872), and Fresno (1872). The modern day town of Herndon, about 10 miles northwest of downtown Fresno on the banks of the San Joaquin River, was originally known as Sycamore and had its start as a railroad station stop on Southern Pacific's rail line along the east side of the San Joaquin Valley. Other early settlements emerged in the Central Valley more as a consequence of the Stockton-Los Angeles Road and Butterfield Overland Stage Company line, which ran between the major urban centers of the state. For example, the town of Firebaugh to the north of the Project area on the San Joaquin River began in 1852 when a ferry was built at the site; it later had a toll road from the river crossing and a stage route also passed through Firebaugh.

Gold in the southern Sierra Nevada Foothills attracted the first large influx of settlers to what is now Madera, Merced, and Fresno counties beginning in 1849. Towns like Millerton, now under Millerton Lake, were established at this time. Soon thereafter, settlers began to occupy the eastern San Joaquin Valley in this area. These were luckless miners and newcomers who recognized the agricultural potential of the valley and the need for food in the mining camps. Numerous individuals purchased land and established ranches on the vast and largely vacant plains by the mid-1850s. Although private ranches of several hundred acres existed, much of the land was unreserved public domain and cattle grazed freely on an open range from the Sierra Nevada Foothills to the Coast Range.

Livestock ranching grew and prospered into the late 1860s. A large number of immigrants from the Ohio Valley and Missouri settled in the San Joaquin Valley during this era; many drove cattle with them across the plains from the Midwest. Along with their cattle, they brought with them the Anglo ranching traditions from the Midwest characterized by favoring European breeds, keeping fenced pastures, raising hay for winter feed, maintaining mixed herds of dairy cows and beef cattle, practicing selective breeding, and employing Anglo cowboys and ranch hands. Immigrants also established farms on the plains between the foothills and San Joaquin River lowlands where they primarily raised wheat during the 1860s and 1870s.

The need for water to irrigate the arid San Joaquin Valley became a priority for the economic development of Central Valley towns, especially those laid out along Southern Pacific's railroad track. In 1873, the California State Legislature passed a "No Fence Law," which established agriculture's dominance over ranching. By the late 1880s small-scale irrigated agriculture was in the ascendancy and irrigation companies, colonies, and districts were formed to help promote agriculture, for which the first canals were completed in the 1870s. Passage of the Wright Act in 1887 provided a legal mechanism for landowners to create public irrigation districts and finance major irrigation works to divert water from the major streams flowing west from the Sierra. Successful irrigation enterprises, including land colonies, in the Central Valley allowed specialty crop agriculture to flourish and redefined the region's economy (Tinkham 1923). While crops

such as grapes continued to be common in the early 20th century, the small farm tradition established by the agricultural colonies began to fade.

Early agriculture on the lower part of the Project area was dominated by the huge cattle ranching operation conducted by Henry Miller and Charles Lux. Miller and Lux developed massive ranching and farming operations on their property along the San Joaquin River (downstream from Mendota), including 140,000 acres in Madera County, more than 150,000 acres in Fresno County, and more than 250,000 acres in Merced County. Miller and Lux also became owners of a host of related subsidiary businesses, including stores, banks, hotels, irrigation systems, and public utilities. Miller and Lux were also pioneers in making use of a large-scale industrial labor force employed in a rural and agricultural setting.

Some of the oldest and most important irrigation works constructed within the Project area were built west of the San Joaquin River in 1871. The central unit of this vast canal and ditch system, constructed by Miller and Lux, was the so-called “Main Canal” of the San Joaquin and Kings River Canal and Irrigation Company. The Main Canal was the first canal built in Fresno County and one of the earliest large irrigation canals in California (W.W. Elliot and Co. 1882). The Main Canal was unique in that it required large amounts of capital and engineering skill, and irrigated thousands of acres. Its construction and success contributed to the 19th century agricultural development on the west side of the San Joaquin Valley (Jackson et al. 1990, Harding 1960, Pisani 1984). Miller and Lux also built the Dos Palos and Temple Slough canals by 1882 from the west bank of the San Joaquin. Over time, canals became increasingly important and extensive.

Irrigation districts started in California after passage of the Wright Act in 1887, which allowed for public tax-supported and democratically controlled irrigation districts. Progressive legislation passed in 1911 through 1913 increased State supervision over district organization and financing and made investing in irrigation district bonds more attractive. Demand for agriculture products also grew around this time and remained high throughout World War I. These conditions contributed to a flurry of district formation in California and to the formation of the Fresno Irrigation District and the Madera Irrigation District.

The Central Valley Project (CVP) was devised by the State, and ultimately built by the Federal government, to resolve California’s chronic water shortage problem. Studies undertaken between 1927 and 1931 resulted in a plan calling for a vast system of canals, massive dams, and reservoirs throughout the state, including most of what became the CVP (Hundley 1992). In 1935, Reclamation was charged with construction of the CVP, which was completed in the early 1950s (Hundley 1992). Reclamation designed the CVP as five fundamental units, operating as an integrated system: Shasta Dam, the Delta-Mendota Canal (DMC), Friant Dam, the Madera and Friant-Kern canals, and the Contra Costa Canal. The core of the system involved the coordinated operation of the other four units for the purpose of delivering Sacramento River water to the arid San Joaquin Valley.

Other water-related projects also flourished in the 20th century. These include the San Joaquin Hatchery, which is situated 1 mile below the Friant Dam, and extensive levee construction to minimize flooding. Major levee construction efforts to minimize flooding along the lower San Joaquin River were related to statewide flood control efforts. In 1913, with formation of the Sacramento and San Joaquin Drainage District, the San Joaquin River and its tributaries also came under jurisdiction of a Federal flood control plan (Bonte 1931). Flood control works on the San Joaquin River in the Project area did not begin to take shape until after World War II when the California State Reclamation Board began purchasing easements and rights-of-way for large overflow areas along the San Joaquin River. In 1955, the State created the Lower San Joaquin Levee District, which acted as a liaison with the U.S. Army Corps of Engineers, the California State Reclamation Board, and California Department of Water Resources (DWR) regarding construction of the Lower San Joaquin River Flood Control Project. Important aspects of the Lower San Joaquin River Flood Control Project include the Chowchilla Bypass, the Eastside Bypass, and the Mariposa Bypass, all of which were completed by 1966 (California State Reclamation Board 1966).

Throughout the historic era, transportation was an important focus of infrastructure development. Over time, foot travel and transportation by horse or stage coach gave way to river, railroad, and ultimately automobile travel. In the early decades of the 20th century the popularity of the automobile led to road improvements and a new State road building program. The main arterial along the eastside of the valley became the Golden State Highway in 1913 and then State Route 99.

9.1.2 Resources in the Project Area

The results presented below are adapted from the *Historic Properties Survey Report, Mendota Pool Bypass and Reach 2B Improvements Project* (Reclamation 2011).

Record Search and Surveys

To establish to what extent the Project footprint has been previously inventoried and what previously recorded resources exist within the areas that might be affected by the individual Project options and the alternatives for the Project, three record searches were conducted: November 2009 (RS#09-439), December 2009 (RS#09-479), and April 2010 (RS#10-173).

All of the literature searches were performed by the South San Joaquin Valley Information Center. The information center staff accessed the records for the Mendota, Firebaugh, and Tranquility U.S. Geological Survey 7.5-minute quadrangles, including a 1-mile radius around the Project footprint. The following references were also reviewed:

- National Register of Historic Places (NRHP) (2010).
- California Register of Historical Resources (CRHR) (2010).
- Office for Historic Preservation Historic Property Directory.
- California State Historical Landmarks (1996 and updates).
- California Inventory of Historic Resources (1976 and updates).

- California Points of Historical Interest (1992 and updates).
- California Department of Transportation's State and Local Bridge Survey (1986 and updates).
- Historical maps, including General Land Office Plat Maps.

In addition to the above references, the recently prepared sensitivity study for the entire SJRRP, *Cultural Resources Sensitivity Study and Research Design for the San Joaquin River Restoration Program, Fresno, Madera, Merced, and Stanislaus Counties, California* (Byrd et al. 2009), was also reviewed given its use in the preparation of the PEIS/R (SJRRP 2011) and its extensive information related to establishing the geoarchaeological[1] sensitivity and relevant cultural resource literature for the Project area.

Previous Survey Coverage

Each of the archaeological surveys reported by the Information Center, that are within or intersect the Project area, are small with respect to the actual acreage surveyed, and are all more than 5 years old, which tends to diminish their reliability (i.e., surveys greater than 5 years of age are typically viewed as dated and resurvey is required due to the potential for changed field conditions). The survey designation, year, and record search number are provided in Table 9-1. According to Byrd et al. (2009), only 6 percent of the area that represents Reach 2 has been previously surveyed. As a result, much of this region is not well known archaeologically.

In addition to the above reports, two recent studies have been conducted within the Project area. DWR prepared both reports in order to clear a proposed geotechnical analysis of potentially impacting unknown cultural resources. The surveys conducted in the vicinity of two of the proposed bore locations did identify cultural deposits potentially related to CA-FRE-45 and CA-FRE-106 (see below) (Gilbert 2011a; Gilbert 2011b). No additional evaluation of the deposits was conducted; however, all proposed geotechnical activities were moved to other locations to avoid potential impacts or effects to these deposits.

Table 9-1.
Previously Conducted Surveys within Project Area

Survey Designation	Year Accomplished	Records Search Number
FR 142	1997	RS#10-173
FR 148	1997	RS#09-439
FR 169	1969	RS#10-173
FR 265 (MA 108)	1998	RS#10-173
FR 388 (MA 897)	1980	RS#09-439
FR 775	1992	RS#09-439

[1] Geoarchaeology refers to the study of landscape change over time and the relative potential for archaeological sites to be either buried or destroyed by geomorphic processes.

Table 9-1.
Previously Conducted Surveys within Project Area

Survey Designation	Year Accomplished	Records Search Number
FR 2164	2004	RS#10-173
FR 2200	2005	RS#10-173
MA 48	1997	RS#10-173

MA 915	2002	RS#09-439

Key:
Survey Designation: FR= Fresno County; MA = Madera County
RS# = record search number;

Previously Recorded Cultural Resources

The previously recorded resources are tabulated in Table 9-2. Prior studies have led to the recording of six resources within the Project area. These include four archaeological sites, Mendota Dam, and a portion of Columbia Canal. Two of the known archaeological sites are located within the proposed river floodplain, one site is located within a potential borrow area, and one site is a generalized location approximately 2 square miles that has minimal overlap with the southeastern end of the Project area.

Table 9-2.
Previously Recorded Cultural Resources within Project Area

Site	Primary Number	Year Recorded	Site Type	Record Search Number
CA-FRE-45	P-10-000045	6/18/1939	Prehistoric	RS#10-173
CA-FRE-106	P-10-000106	2/1/1952	Prehistoric	RS#10-173
CA-FRE-563	P-10-000563	1/16/1975	Prehistoric	RS#09-439, RS#10-173
CA-MAD-301[1]	P-20-000301[1]	2/2/1975	Prehistoric	RS#09-439
Mendota Dam	P-10-003200	10/2/1997	Dam	RS#10-173
Columbia Canal	P-20-002383	12/11/2000	Canal	RS#09-439, RS#09-479

Notes:
[1] "Site" was recorded on the basis of hearsay; no field verification is represented in the site record.

With the exception of the Mendota Dam, the record searches did not identify any previously recorded resources that were previously determined eligible for the NRHP or CRHR. The prehistoric sites identified in the records search are predominantly old recordings of what were likely large habitation sites, but, even at the time of recordation, the majority of the site material had been heavily disturbed by some combination of development, farming, or alluvial processes.

Native American Communication

Information received from the Native American Heritage Commission on December 9, 2009, and December 23, 2009, indicates that no information pertaining to Native American cultural resources within the Project area was found in a review of the sacred lands file. The letters included a list of 14 individuals or organizations who should be contacted with regard to the proposed undertaking, and who may have information regarding cultural resources in the area. Letters were sent to each contact on November 30, 2010. One response has been received to date from Jerry Brown of the Chowchilla Tribe of Yokuts. Mr. Brown expressed interest in participating in any discussions regarding identified archaeological resources, if any.

Project-level Cultural Surveys

At the time of the cultural resources surveys in August 2010, access to privately owned property had been granted to only a portion of the Project area. Access had been granted primarily to parcels south of the San Joaquin River, and only limited access was available north of the river. The Project area represents about 5,360 acres. Due to the lack of access to much of the northern half of the Project area, as well as portions of the southern half, about 2,020 acres (38 percent) of the Project area has been subjected to survey to date. A team of four archaeologists conducted the survey using 20-meter transect intervals. Areas that were wet herbaceous habitat or seasonal wetland, especially within the North Loop oxbow (River Mile 207.7), were more cursorily surveyed due to a lack of surface visibility.

Archaeological Resources

With the exception of a single obsidian isolate, no archaeological resources were identified during the course of the surveys conducted for this EIS/R. The majority of the parcels were under some form of agriculture and therefore visibility of the surface varied from fair to good. The parcels were planted as orchards and vineyards, and consisted of riparian habitat along the banks of the river. None of the previously recorded prehistoric sites were relocated. In each case, the identified resource was described as almost destroyed or soon to be destroyed at the time of record. Furthermore, most of the sites were recorded over 40 years ago. Given the intensity of farming in the area, as well as a highly active riverine system nearby, an intact surface manifestation of cultural activity that was previously recorded is unlikely to have persisted to the present day. The isolated obsidian flake identified during field surveys for the current Project is likely a re-deposited artifact from one of the numerous sites located nearby and could lack any context to a known deposit or site.

Nevertheless, as indicated by Byrd et al. (2009) and SJRRP (2010), the potential for buried archaeological resources is high throughout the Project area. The alluvial environment near the San Joaquin River would generally have a high potential to contain buried archaeological sites. This is because large portions of the Central Valley are covered by Late Holocene landforms that include floodplain deposits laid down beginning about 4,000 years ago and continuing into the historic period. Even sites a few hundred years old may be buried (Gilbert 2011a, Byrd et al. 2009). Indeed, the subsurface analysis conducted by Gilbert (2011a; 2011b) suggested that at least two locations within

the Project area may contain intact subsurface deposits associated with the recorded locations of CA-FRA-45 and CA-FRA-106.

Architectural Resources

An historical architecture survey and evaluation program was conducted for the Project area in 2010 by JRP Historical; the following results are summarized from this report (SJRRP 2010). This survey has included a field check of all previously evaluated resources, and the SJRRP has prepared the appropriate recordation documents, either as an update or as a new Department of Parks and Recreation 523 form, to verify current conditions and previous evaluations.

Table 9-3 below summarizes the historical architectural findings for those resources identified within the Project area and list their status codes, which describe their eligibility to the NRHP and/or CRHR (SJRRP 2010). Of the 13 built environment resources identified within the Project area, five have been previously evaluated for the NRHP. None of the other eight newly identified resources were found to be eligible for the NRHP or CRHR.

The Mendota Dam was determined eligible for the NRHP and is listed in the CRHR. Constructed in 1917, the Mendota Dam is significant, presumably at the State level, under Criterion A, for its association with the Miller and Lux Company's irrigation works in the Central Valley. The DMC appears individually eligible for the National Register (and California Register) under Criterion A, presumably at the State level of significance, within the context of development, construction, and operation of the CVP. The period of significance was identified from 1945 to 1951, its period of construction. Both the Mendota Dam and DMC are considered historic resources under the California Environmental Quality Act (CEQA).

Table 9-3.
Property Status Under the National Register and California Register

Name/Address	Year Built	County	APN	OHP Status Code
Properties Determined Eligible or Previously Found to Appear Eligible for the National Register and California Register				
Mendota Dam	1917	Fresno; Madera	N/A	2S2
Delta-Mendota Canal	1946-1951	Fresno	N/A	3S
Properties Determined Not Eligible for the National Register or California Register				
Columbia Canal and Ridge Ditch	ca. 1880s; 1891-1924	Madera	N/A	6Z, 6Y
Main Canal	1872	Fresno	N/A	6Z, 6Y
Outside Canal	1900	Fresno	N/A	6Z, 6Y
Properties that Appear Not Eligible for the National Register or California Register as a Result of the Current Study				
643 North San Mateo Avenue	ca. 1962-1970s	Fresno	013-040-25S	6Z
San Joaquin River and Fresno Slough Levees	1947-1955	Fresno; Madera	N/A	6Z

Table 9-3.
Property Status Under the National Register and California Register

Name/Address	Year Built	County	APN	OHP Status Code
Mowry Canal	ca. 1910	Fresno	N/A	6Z
Mowry Ranch	ca. 1950-1968	Fresno	013-020-28	6Z
3614-3618 Bass Avenue	1961-1965	Fresno	013-020-40	6Z
Helm Ditch	ca. 1899-1913	Fresno	N/A	6Z
Bass Avenue	1957-1961	Fresno	013-020-14ST	6Z
Main Firebaugh Canal (Intake Canal)	1919-1929	Fresno	N/A	6Z

APN = assessor's parcel number
ca. = circa
OHP = Office for Historic Preservation
N/A = not applicable
Status Code 2S2 = Individual property determined eligible for National Register by a consensus through Section 106 process. Listed in the California Register.
Status Code 3S = Appears eligible for National Register as an individual property through survey evaluation.
Status Code 6Y = Determined ineligible for National Register by consensus through Section 106 process – Not evaluated for California Register or Local Listing.
Status Code 6Z = Found ineligible for National Register, California Register or Local designation through survey evaluation.

9.2 Regulatory Setting

Under Federal and State law, effects to significant cultural resources (e.g., archaeological remains, historic-period structures, and traditional cultural properties) must be considered as part of the environmental analysis of a proposed project. Criteria for defining significant cultural resources are included in 36 Code of Federal Regulations (CFR) Part 63 (Determinations of Eligibility for Inclusion in the NRHP); the NHPA of 1966, as amended (16 United States Code [USC] 470 et seq.); and CEQA. In addition, 36 CFR 800 outlines the compliance process for Section 106 of the NHPA.

9.2.1 Federal

National Historic Preservation Act (36 CFR Part 800 Implementing Regulations Section 106)

The NHPA of 1966 is the primary Federal legislation which outlines the Federal government's responsibility to cultural resources. More specifically, Section 106 of the NHPA and its implementing regulations located at 36 CFR Part 800, outline the Federal government's responsibility in identifying and evaluating cultural resources. Other applicable Federal cultural resources laws and regulations that could apply include, but are not limited to, the Native American Graves Protection and Repatriation Act, and the Archaeological Resources Protection Act.

Section 106 of the NHPA requires the Federal government to take into account the effects of an undertaking on cultural resources listed on or eligible for listing on the NRHP and afford the Advisory Council on Historic Preservation a reasonable opportunity to comment. Those resources that are on or eligible for inclusion in the NRHP are referred to as historic properties. The 36 CFR Part 800 regulations describe the Section 106 process. They outline the steps the Federal agency takes to identify cultural resources and the level of effect that the proposed undertaking will have on historic properties. An undertaking is defined as any "…project, activity or program funded in whole or in part under the direct or indirect jurisdiction of a Federal agency, including:

- Those carried out by or on behalf of the agency.
- Those carried out with federal assistance.
- Those requiring a federal permit, license, or approval.
- Those subject to state or local regulation administered pursuant to a delegation or approval by a Federal agency [Section 301(7) 16 USC 470w(7)]."

It is the initiating of an undertaking that begins the Section 106 process. Once an undertaking is initiated the Federal agency must first determine if the action is the type of action that has the potential to affect historic properties. If the action is the type of action that has the potential to affect historic properties, the Federal agency must: 1) identify the area APE, 2) determine if historic properties are present within that APE, 3) determine the effect that the undertaking will have on historic properties, and 4) consult with the SHPO to seek concurrence on Federal agencies findings. In addition, the Federal agency is required through the Section 106 process to consult with Indian Tribes concerning the identification of sites of religious or cultural significance, and to consult with individuals or groups who are entitled to be consulting parties or have requested to be consulting parties. If the undertaking will result in adverse effects to historic properties, these adverse effects must be resolved in consultation with the SHPO and other parties identified during the Section 106 process before the undertaking can proceed to implementation.

Historical significance is assessed by applying the NRHP criteria as defined by 36 CFR Part 60.4. Historic properties need to possess both historical significance and integrity to be considered eligible for inclusion in the NRHP. If a property has historical significance but does not retain sufficient integrity, the property will not be considered eligible for inclusion in the NRHP. Conversely, if a property has maintained a high degree of integrity but has no historical significance, then it will also not be considered a historic property.

NRHP guidelines describe historical significance as the "quality of significance in American history, architecture, archeology, engineering and culture" that is "present in districts, sites, buildings, structures, and objects." Properties eligible for the NRHP can be significant on a national, state, or local level and must meet at least one of the following historical significance criteria:

- Criterion A: Properties that are associated with events that have made a significant contribution to the broad patterns of our history.
- Criterion B: Properties that are associated with the lives of persons significant in our past.
- Criterion C: Properties that embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction.
- Criterion D: Properties that have yielded or may be likely to yield, information important in prehistory or history.

Integrity is determined by applying the seven aspects of integrity to the historic resource: location, design, setting, materials, workmanship, feeling, and association. A resource will possess several, if not most, of the seven aspects of integrity to convey the historical significance of the resource.

Section 101(d)(6)(A) of the NHPA allows properties of traditional religious and cultural importance to a Native American tribe to be determined eligible for NRHP inclusion. In addition, a broader range of Traditional Cultural Properties are also considered and may be determined eligible for or listed in the NRHP. Traditional Cultural Properties are places associated with the cultural practices or beliefs of a living community that are rooted in that community's history may be eligible because of their association with cultural practices or beliefs of living communities that (a) are rooted in that community's history, and (b) are important in maintaining the continuing cultural identity of the community. In the NRHP programs, "culture" is understood to mean the traditions, beliefs, practices, lifeways, arts, crafts, and social institutions of any community, be it an Indian tribe, a local ethnic group, or the nation as a whole.

Native American Graves Protection and Repatriation Act

The Native American Graves Protection and Repatriation Act (25 USC § 3001 to 3013, 43 CFR Part 10) sets provisions for the removal and inadvertent discovery of human remains and other cultural items on Federal and tribal lands. The Native American Graves Protection and Repatriation Act clarifies the ownership of human remains and sets forth a process for repatriation of human remains and associated funerary objects and sacred religious objects to the Native American tribes or tribes likely to be lineal descendants or culturally affiliated with the discovered remains or objects.

Archaeological Resources Protection Act

The Archaeological Resources Protection Act (16 USC § 470aa-mm) sets forth requirements that must be met before Federal authorities can issue a permit to excavate or remove any archeological resource on Federal or Indian lands. The curation requirements of artifacts, other materials excavated or removed, and the records related to the artifacts and materials are also described.

Executive Order 13007 (Indian Sacred Sites) and April 29, 1994, Executive Memorandum

EO 13007 requires that Federal agencies with land management responsibilities accommodate access to and ceremonial use of Indian sacred sites by Indian religious practitioners. This EO further requires that those agencies avoid adversely affecting the physical integrity of such sacred sites. Where appropriate, agencies also must maintain the confidentiality of sacred sites. Other requirements stipulate that the agencies provide reasonable notice of proposed actions or land management policies that may restrict future access to or ceremonial use of sacred sites, or that may adversely affect the physical integrity of sacred sites. The agencies must comply with the April 29, 1994, executive memorandum, "Government-to-Government Relations with Native American Tribal Governments."

Reclamation received information from Native American Heritage Commission about which Native American groups would be interested in Project actions. Reclamation mailed letters requesting their comments on November 30, 2010. Also, these Native American groups were notified of the public scoping meetings and are included in the distribution list for this EIS/R. Reaching out to Native American groups, including the groups that participated in scoping and review of this EIS/R, demonstrates that Reclamation has complied with EO 13007. If an Indian sacred site is encountered within the Project area, measures will be implemented to prevent any restriction of access or effect on the site's physical integrity. Continued compliance with this EO would be demonstrated through implementation of mitigation measures, as needed.

9.2.2 State of California

Under CEQA, the lead agency must consider potential effects to important or unique cultural resources. While the language is somewhat different between NHPA and CEQA, the definitions of eligible properties and of adverse impacts are essentially the same. Evaluations under CEQA consider a resource's potential eligibility for inclusion in the CRHR.

California Register of Historical Resources

California Public Resources Code section 5024.1 establishes the CRHR. The register lists all properties considered to be significant historical resources in the State. The CRHR includes all properties listed or determined eligible for listing on the NRHP, including properties evaluated under Section 106 of the NHPA. The criteria for listing are similar as those of the NRHP. CEQA section 21084.1 requires a finding of significance for substantial adverse changes to historical resources and defines the term "historical resources." CEQA section 21083.2 and State CEQA Guidelines section 15064.5, subdivision (c) provide further definitions and guidance for archaeological sites and their treatment.

California Native American Graves Protection and Repatriation Act

The California Native American Graves Protection and Repatriation Act (Health & Saf. Code, § 8010 et seq.) establishes a State repatriation policy intent that is consistent with and facilitates implementation of the Federal Native American Graves Protection and Repatriation Act. The act strives to ensure that all California Indian human remains and

cultural items are treated with dignity and respect, and encourages voluntary disclosure and return of remains and cultural items by publicly funded agencies in California.

Executive Order B-10-11

EO B-10-11 was signed by Governor Brown on September 9, 2011. This EO establishes the role and responsibilities of the Governor's Tribal Advisor and directs State agencies and departments under the Governor's executive control to communicate and consult with Federally recognized tribes, other California Native Americans, and representatives of tribal governments to provide meaningful input into the development of legislation, regulations, rules, and policies on matters that may affect tribal communities.

Assembly Bill 52

AB 52, signed on September 25, 2014, amends CEQA, creates a new category of environmental resources: "tribal cultural resources," and imposes new requirements for consultation for projects that may affect a tribal cultural resources (Public Resources Code sections 5097.94, 21073, 21074, 21080.3.1, 21080.3.2, 21082.3, 21083.09, 21084.2, and 21084.3).

9.2.3 Local and Regional

There are no known regional or local plans or policies related to cultural resources.

9.3 Environmental Consequences and Mitigation Measures

9.3.1 Impact Assessment Methodology

To assess impacts to cultural resources, historic properties and potential buried archaeological resources within the Project area were identified (see Section 9.1.4). A search for historic properties within the Project area was conducted (SJRRP 2010). This step was intended to provide a baseline for comparison to Project alternatives and to initiate the Section 106 process between Reclamation and SHPO. Cultural surveys were also conducted in the Project area using 20-meter transect intervals, where access to private- or publicly-owned property had been granted.

To assess impacts to identified cultural resources within the Project area, the construction and operation of the Project was evaluated relative to the identified historic properties and potential buried archaeological resources to determine the potential for adverse effects to those resources. For example, Project actions that require ground disturbance have the potential to cause adverse effects to archaeological resources and Project actions that cause physical destruction or visual setting alterations have the potential to cause adverse effects to the built environment.

9.3.2 Significance Criteria

Federal Criteria

National Environmental Policy Act

Pursuant to National Environmental Policy Act (NEPA) regulations (40 CFR 1500–1508), Project effects are evaluated based on the criteria of context and intensity. Context means the affected environment in which a proposed project occurs. The severity of the impact is examined in terms of the type, quality, and sensitivity of the resource involved; the location and extent of the impact; the duration of the impact (short- or long-term); and other considerations of context. Intensity means the degree or magnitude of a potential effect where the effect is determined to be negligible, moderate, or substantial.

Pursuant to NEPA, in considering whether an action may "significantly affect the quality of the human environment," an agency must consider, among other things, the unique characteristics of the geographic area such as proximity to historic or cultural resources (40 CFR 1508.27, subd. [b][3]), and the degree to which the action may adversely affect districts, sites, linear features, landscapes, buildings, structures, or objects listed, or eligible for listing, in the NRHP or may cause loss or destruction of significant scientific, cultural, or historical resources (40 CFR 1508.27 subd. [b][8]).

National Historic Preservation Act (16 USC Section 470 et seq.)

The NHPA establishes the Federal government policy on historic preservation and the programs including the NRHP, through which this policy is implemented. Under the NHPA, significant cultural resources, referred to as historic properties, include any prehistoric or historic district, site, building, structure, object, or landscape included in, or eligible for inclusion in, the NRHP. Historic properties also include resources determined to be National Historic Landmarks, which are nationally significant historic places designated by the Secretary of the Interior because they possess exceptional value or quality in illustrating or interpreting United States heritage. A property is considered historically significant if it meets one of the NRHP criteria and retains sufficient historic integrity to convey its significance. This act also established the Advisory Council on Historic Preservation, an independent agency responsible for implementing Section 106 of NHPA by developing procedures to protect cultural resources included in, or eligible for inclusion in, the NRHP. Regulations are published in 36 CFR Part 60 and 63, and 36 CFR Part 800.

Section 106 affords the Advisory Council on Historic Preservation and SHPO, as well as other consulting parties, a reasonable opportunity to comment on any undertaking that would adversely affect historic properties listed in or eligible for NRHP listing.[2] SHPO administers the national historic preservation program at the State level, review NRHP nominations, maintain data on historic properties that have been identified but not yet nominated, and consult with Federal agencies during Section 106 review.

[2] Mitigation required under Section 106 has the potential to bring significant impacts to less than significant levels for NEPA/CEQA.

The NRHP uses the National Register eligibility criteria (36 CFR 60.4) to evaluate significance. The criteria for evaluation are as follows:

- Properties that are associated with events that have made a significant contribution to the broad patterns of our history.
- Properties that are associated with the lives of persons significant to our past.
- Properties that embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master; or that possess high artistic values; or that represent a significant and distinguishable entity whose components may lack individual distinction.
- Properties that have yielded, or may be likely to yield, information important in prehistory or history.

Section 101(d)(6)(A) of the NHPA allows properties of traditional religious and cultural importance to a Native American tribe to be determined eligible for NRHP inclusion. In addition, a broader range of Traditional Cultural Properties are also considered and may be determined eligible for or listed in the NRHP. Traditional Cultural Properties are places associated with the cultural practices or beliefs of a living community that are rooted in that community's history may be eligible because of their association with cultural practices or beliefs of living communities that (a) are rooted in that community's history, and (b) are important in maintaining the continuing cultural identity of the community. In the NRHP programs, "culture" is understood to mean the traditions, beliefs, practices, lifeways, arts, crafts, and social institutions of any community, be it an Indian tribe, a local ethnic group, or the nation as a whole.

State Criteria

State CEQA Guidelines section 15064.5 provides specific guidance for determining the significance of impacts on historic and unique archaeological resources. Under CEQA, these resources are called historical resources whether they are of historic or prehistoric age. CEQA section 21084.1 defines historical resources as those listed, or eligible for listing, in the CRHR, or those listed in the historical register of a local jurisdiction (county or city). NRHP-listed historic properties located in California are considered historical resources for the purposes of CEQA and are also listed in the CRHR. The CRHR criteria for listing such resources are based on, and are very similar to, the NRHP criteria. CEQA section 21083.2 and State CEQA Guidelines section 15064.5, subdivision (c) provide further definitions and guidance for archaeological sites and their treatment. Section 15064.5 also prescribes a process and procedures for addressing the existence of, or probable likelihood, of Native American human remains, as well as the accidental discovery of any human remains within the Project area. This includes consultations with appropriate Native American tribes.

Guidelines for the implementation of CEQA define procedures, types of activities, persons, and public agencies required to comply with CEQA. CEQA section 21083.2 defines "unique archaeological resources" as "any archaeological artifact, object, or site about which it can be clearly demonstrated that, without merely adding to the current body of knowledge, there is a high probability that it meets any of the following criteria:

- Contains information needed to answer important scientific research questions and that there is a demonstrable public interest in that information.
- It has a special and particular quality, such as being the oldest of its type or the best available example of its type.
- Is directly associated with a scientifically recognized important prehistoric or historic event."

CEQA section 21084.1 also further defines "adverse effect" on a historical resource as "a project that may cause a substantial adverse change in the significance of an historical resource is a project that may have a significant effect on the environment." CEQA defines substantial adverse change in the significance of a resource as the physical demolition, destruction, relocation, or alteration of the resource or its immediate surroundings such that the significance of the resource is materially impaired (State CEQA Guidelines, § 15064.5, subd. (b)(1)). The significance of a historical resource is considered to be materially impaired when a project demolishes or materially alters in an adverse manner those characteristics that convey its historical significance and that justify its inclusion on an historical resource list (State CEQA Guidelines, § 15064.5, subd. (b)(2)).

9.3.3 Impacts and Mitigation Measures

This section provides an evaluation of the long-term and temporary effects of the Project alternatives on cultural resources. It includes analyses of potential effects relative to No-Action conditions in accordance with NEPA and potential impacts compared to existing conditions to meet CEQA requirements. With respect to cultural resources, the environmental impact issues and concerns are:

1. Effects on Archaeological Resources from Ground Disturbing Activities during Construction.
2. Effects on Historical Properties Listed or Eligible for Listing in the National or California Register.
3. Effects on Cultural Resources during the Operations and Maintenance Phase of the Project.

Other cultural-related issues covered in the PEIS/R are not covered here because they are programmatic in nature and/or are not relevant to the Project area. These issues include disturbance or destruction of cultural resources around Millerton Lake and disturbance or destruction of cultural resources along the San Joaquin River downstream from the Merced River.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. However, other proposed actions under the SJRRP would be implemented, including habitat restoration, augmentation of river flows, and reintroduction of salmon. Without the Project in Reach 2B, however, these Program-level activities would not achieve Settlement goals. The potential effects of the No-Action Alternative are described below.

The analysis is a comparison to existing conditions, and no mitigation is required for No-Action.

Impact CUL-1 (No-Action Alternative): *Effects on Archaeological Resources from Ground Disturbing Activities during Construction.* Similar to existing conditions, Project features would not be developed in the No-Action Alternative and therefore Project construction activities would not occur. There would be **no impact**.

Impact CUL-2 (No-Action Alternative): *Effects on Historical Properties Listed or Eligible for Listing in the National or California Register.* Mendota Dam was determined eligible for the NRHP and is listed in the CRHR, while DMC has been recommended as eligible to NRHP (see Section 9.1.2). Changes to Mendota Dam and the DMC as a result of the Project-level actions would not occur. There would be **no impact**.

Impact CUL-3 (No-Action Alternative): *Effects on Cultural Resources during the Operations and Maintenance Phase of the Project.* Under the No-Action Alternative, operations would continue similar to current operations and increased flows. Maximum channel conveyance would be limited to the existing capacity in Reach 2B. Therefore, there would be no new types of impacts to cultural resources (archaeological sites, historic-era structural resources, and traditional cultural properties/areas of concern). Archaeological sites within and immediately adjacent to the San Joaquin River would continue to be potentially impacted by Friant Dam releases and downstream diversions during ongoing operations under the No-Action Alternative. The scale of these events would continue to vary greatly interannually, with the most damage to resources occurring during occasional wet years with major flood events. Cultural resources outside of the existing levee alignment would continue to be potentially degraded by agricultural activities. This impact would be **potentially significant**. No mitigation is required for No-Action.

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

Alternative A would entail construction of Project facilities including a Compact Bypass channel, a new levee system encompassing the river channel with a narrow floodplain, and the South Canal. Other key features include construction of the Mendota Pool Dike (separating the San Joaquin River and Mendota Pool), a fish barrier below Mendota Dam, and the South Canal bifurcation structure and fish passage facility, modification of the San Mateo Avenue crossing, and the removal of the San Joaquin River control structure at the Chowchilla Bifurcation Structure. Construction activity is expected to occur intermittently over an approximate 132-month timeframe.

Impact CUL-1 (Alternative A): *Effects on Archaeological Resources from Ground Disturbing Activities during Construction.* Compared to the No-Action Alternative, archaeological sites could be subject to adverse effects during construction activities under Alternative A. Soil excavation or compaction resulting from the use of heavy machinery on the construction site itself or in staging areas may affect the integrity of artifact-bearing deposits associated with known and as-yet undiscovered archaeological sites. Project alternatives entail a large amount of soil “borrowing” (as described in

Chapter 2, Section 2.2.4) from areas surrounding the San Joaquin River, which is a sensitive area for archaeological resources, particularly for buried deposits.

Adverse effects could occur to known archaeological resources as a result of ground disturbing activities, including soil borrowing. Cultural resources surveys conducted in the Project area prior to geotechnical activities have revealed buried cultural deposits at CA-FRA-45 and CA-FRA-106 (Gilbert 2011a; Gilbert 2011b). These deposits have not been evaluated for NRHP or CRHR eligibility. Additional buried elements could exist in these locations.

Adverse effects could also occur near the river channel. The alluvial deposits adjacent to the river are considered highly sensitive for buried archaeological resources. Unknown or unrecorded archaeological resources that are not observable when conducting standard surface archaeological inspection may exist within the Project area. Construction-related ground disturbance in areas that could contain unknown archaeological resources could cause substantial adverse changes in the significance of historical resources, unique archaeological resources, or historic properties. Currently about 38 percent of the Project area has been inventoried for archaeological resources. It is estimated that a large number of cultural resources would be documented within this reach after full inventory efforts (Byrd et al. 2009).

Compared to existing conditions, Alternative A would result in greater impacts to cultural resources as described in the preceding paragraphs. Construction of the Project could result in possible substantial effects on known or unknown archaeological deposits from ground-disturbing construction operations associated with the Project. This would cause substantial adverse changes in the significance of an archaeological resource pursuant to the NHPA (36 CFR Part 800) and is therefore considered an adverse effect under Section 106. Construction-related ground disturbance in areas that could contain unknown historical resources or properties could cause adverse changes in the significance of archaeological resources pursuant to State CEQA Guidelines section 15064.5. This impact would be **potentially significant**.

Mitigation Measure CUL-1A (Alternative A): *Comply with Section 106 of the NHPA or Equivalent.* Reclamation will comply with Section 106 of the NHPA during subsequent site-specific studies as access is granted to the large area of unsurveyed lands within the Project area for which permission to enter was not granted. Reclamation must comply with Public Resources Code sections 5024 and 5024.5, which require Federal agencies to confer with SHPO before implementing any project with the potential to affect historical resources listed in or potentially eligible for inclusion in the NRHP or registered as or eligible for registration as a State historical landmark.

Site-specific environmental reviews will be conducted before all ground-disturbing activities. The following mitigation measures, consisting of inventory, evaluation, and treatment processes, will be conducted by Reclamation as part of the environmental reviews to ensure compliance with Section 106 of the NHPA or Public Resources Code sections 5024 and 5024.5, as applicable. Coordination will continue with the relevant Native American tribes in the area, as necessary to complete these compliance processes.

Implementation Action: Inventory, evaluation, and treatment processes will be implemented during subsequent site-specific studies and as access is granted. These measures include conducting cultural resources surveys of portions of the Project area that have not been surveyed, planning activities to avoid known cultural resources, evaluating the significance of resources that cannot be avoided, and developing treatment process for significant resources.

- *Conduct cultural resources surveys of portions of the Project area that have not been surveyed.* Before any ground disturbance takes place in the Project area (including areas of ancillary activities, such as staging areas and access routes), cultural resource surveys covering the Project area will be conducted to locate and record cultural resources. Where appropriate, subsurface discovery efforts also will be undertaken to identify buried archaeological sites.
- *Plan activities to avoid known cultural resources.* Before carrying out ground-disturbing activities, areas that have been delineated as containing cultural resources will be demarcated, and all ground-disturbing or related activities will be planned to avoid these areas.
- *Evaluate significance of resources that cannot be avoided.* If cultural resources cannot be avoided through careful planning of the activities associated with the Project, additional research or test excavation (as appropriate) will be undertaken to determine whether the resources are significant.
- *Develop treatment process to mitigate effects of Project upon significant resources.* Impacts on significant resources that cannot be avoided will be mitigated in a manner that is deemed appropriate for the particular resource. Mitigation for significant resources may include, but are not limited to, data recovery, public interpretation, performance of a Historic American Building Survey or Historic American Engineering Record, or preservation by other means.

Location: In Project areas with subsequent site-specific studies and where additional access is granted.

Effectiveness Criteria: Successful compliance with Section 106 of the NHPA or Public Resources Code sections 5024 and 5024.5, as applicable.

Responsible Agency: Reclamation.

Monitoring/Reporting Action: Reclamation would report to SHPO and the consulting parties.

Timing: Site-specific environmental reviews will be conducted prior to ground-disturbing activities. Coordination will continue with the relevant Native American tribes in the area, as necessary to complete compliance processes.

Mitigation Measure CUL-1B (Alternative A): ***Conduct Subsurface Testing and/or Archaeological Monitoring in Proximity to Identified Sites or Areas of Sensitivity.*** Ground-disturbing activities that have the potential to affect archaeological resources may occur in areas that have been identified as either the location of a known archaeological site, or in as an area known to be sensitive for the presence of buried cultural resources. Implementation of the following measures would reduce potential impacts to known archaeological sites and areas of sensitivity.

Implementation Action: Prior to Project implementation, subsurface geoarchaeological testing will be conducted in areas where ground-disturbing construction activities are proposed in native sediments/soils near known archaeological resources, as well as any areas of proposed disturbance in areas identified by Byrd et al. (2009) as having high or very high sensitivity for buried archaeological resources, in order to rule-out the presence of buried archaeological resources within the Project's areas of subsurface disturbance. If subsurface testing is determined not to be feasible and/or the results of testing are inconclusive, an archaeological monitor approved by Reclamation and/or CSLC staff will be present during all ground-disturbing activities in those same areas described above.

In the event that cultural resources are exposed during construction, the monitor will be empowered to temporarily halt activities in the immediate vicinity of the discovery while it is evaluated for significance. If, in consultation with interested parties, it is determined that the cultural resources exposed are significant archaeological resources, and if Project activities cannot feasibly avoid the resource, additional measures will be implemented (see Mitigation Measures CUL-1C and CUL-1D below). Where necessary, Reclamation will seek Native American input and consultation.

Location: Construction areas with ground-disturbing activities occurring in native sediments/soils near known archaeological resources, as well as any areas of proposed disturbance in areas determined to be highly or very highly sensitive for buried archaeological resources by Byrd et al. (2009) or a subsequent Project-specific geoarchaeological sensitivity analysis.

Effectiveness Criteria: Performance tracking of this mitigation measure is based upon successful implementation and the approval of the documentation by SHPO and appropriate consulting parties.

Responsible Agency: Reclamation.

Monitoring/Reporting Action: Geoarchaeological testing will occur prior to, and/or archaeological monitoring will occur during, specified ground-disturbing activities. Reclamation will report to SHPO and the consulting parties.

Timing: Geoarchaeological testing will occur prior to ground disturbing activities. Active archaeological monitoring, as necessary, will occur throughout the duration of these specific ground-disturbing activities.

Mitigation Measure CUL-1C (Alternative A): *Halt Work in the Event of an Archaeological Discovery.* If any cultural resources are discovered during ground-disturbing activities, all work in the immediate vicinity of the resources will be halted, and an archaeologist approved by Reclamation and/or CSLC staff will assess the significance of the find. If the discovery is determined to be significant, work may proceed on other parts of the Project area while avoidance or mitigation alternatives are being developed and carried out.

Implementation Action: Reclamation will prepare and implement an Archaeological Treatment Plan, which will be developed in coordination with interested parties. This plan will include an approach for addressing unanticipated discoveries and will detail the specific procedures to be followed if archaeological materials are found during construction.

Reclamation will notify California State Lands Commission (CSLC) staff if the find is a cultural resource on lands under the jurisdiction of the CSLC. Reclamation will comply with all applicable rules and regulations promulgated by CSLC with respect to cultural resources in submerged lands.

If human remains are encountered, Reclamation will comply with applicable laws and regulations regarding notification and disposition of the remains. If the coroner determines that the remains are Native American, the coroner would notify the Native American Heritage Commission under Health and Safety Code section 7050.5 and Reclamation and/or CSLC staff would ensure that the discovery is treated in accordance with the provisions of Public Resources Code section 5097.98, subdivisions (a)-(d).

If any find is determined to be significant, Reclamation and/or CSLC staff, the Project archaeologist, and interested parties will determine the appropriate avoidance measures. All significant cultural materials recovered will be—as necessary and at the discretion of the Project archaeologist and with input from Native American representatives—subject to scientific analysis, professional museum curation,[3] and documentation according to current professional standards. In considering any suggested mitigation proposed to mitigate impacts on historic properties, historical resources, or unique archaeological resources, a determination will be made on whether avoidance is feasible in light of factors such as the nature of the find, Project design, costs, and other considerations.

[3] Curation is management and care of collections according to standard professional practice, which may include inventorying, accessing, labeling, cataloging, identifying, evaluating, documenting, storing, maintaining, periodically inspecting, and/or conserving original collections.

If, in consultation with interested parties, it is determined that a significant archaeological resource is present and that the resource could be adversely affected, one of the following actions may be followed, as feasible:

- If prudent and feasible, redesign the Project to avoid any adverse effect on the significant archaeological resource.
- Implement Mitigation Measure CUL-1D, Intentional Site Burial for Site Preservation.
- Implement an archaeological data recovery program (ADRP). If the circumstances warrant an ADRP, a data recovery program will be conducted. The scope of the ADRP will be determined together with the Project archaeologist and interested parties. The archaeologist will prepare a draft ADRP, which would identify the scientific/historical research questions that are applicable to the expected resource, the data classes the resource is expected to possess, and how the expected data classes would address the applicable research questions. Destructive data recovery methods will not be applied to portions of the archaeological resources not impacted by the Project.

Location: Active construction areas during ground-disturbing activities.

Effectiveness Criteria: Performance tracking of this mitigation measure will be based on successful implementation and approval of documentation by SHPO and appropriate consulting parties.

Responsible Agency: Reclamation and CSLC.

Monitoring/Reporting Action: Reclamation and/or CSLC staff will report to SHPO and the consulting parties.

Timing: Mitigation will be ongoing over the construction timeframe.

Mitigation Measure CUL-1D (Alternative A): *Plan an Intentional Site Burial Preservation in Place*. If Project engineering concludes that avoidance is not feasible, a process to determine whether the site can be preserved through intentional site burial will be considered. When complete avoidance is not possible, preservation-in-place is the preferred form of mitigation for a "historical resource of an archaeological nature" because it retains the relationships between artifact and context and may avoid conflicts with groups associated with the site, pursuant to Public Resources Code section 15126.4, subdivision (b)(3)(A). The process presented in overview here will be specified in detail in the Archaeological Treatment Plan.

Implementation Action: To intentionally bury a site, it will be necessary to conduct test excavations to determine the vertical and horizontal extent of the identified resources. If excavations have not yet been conducted for the purpose of evaluating the site for eligibility in accordance with section 106 of the NHPA, an archaeologist approved by Reclamation and/or CSLC staff will conduct a

formal excavation of the site to delineate the site boundaries and to determine the site's eligibility for the CRHR or NRHP.

If the site is found to be eligible or potentially eligible, and if avoidance is not feasible, then consideration will be given to intentional site burial. The Project archaeologist will, in consultation with interested parties, delineate the site boundaries, and prepare and implement a design plan to dictate the conditions of the intentional site burial according to the recommendations discussed in the National Park Service Technical Brief Number 5, *Intentional Site Burial: A Technique to Protect Against Natural or Mechanical Loss* (Thorne 1991).

Among the requirements of an effective capping design, the mechanical process of burying the site must be designed in a manner that ensures that the site matrix is protected during the placement process. Preconstruction testing can be used to determine the construction equipment and fill material load limits that are allowable without causing compression or warpage of the artifact and feature components of the site.

If the preconstruction testing determines that compression or warpage of the site is probable and that site capping would not reduce effects to less-than-significant levels, additional mitigation, such as data recovery, would be necessary. Furthermore, if it is determined that the engineering requirements of the Project at the location of the site prohibit the effective avoidance of the site or if the surrounding conditions prohibit the protection or preservation of the archaeological components, data recovery may be the only feasible mitigation (see Mitigation Measure CUL-1C, above). In addition, Reclamation and/or CSLC staff will make provisions to monitor the site after the burial process is complete.

Location: Active construction areas in the event of an archaeological discovery where avoidance is not feasible and capping can be designed to effectively minimize Project effects to the discovery.

Effectiveness Criteria: Performance tracking of this mitigation measure will be based on successful implementation and the approval of the documentation by SHPO and appropriate consulting parties.

Responsible Agency: Reclamation and CSLC.

Monitoring/Reporting Action: Reclamation and/or CSLC staff will make provisions with the archaeologist to monitor the site after the burial process is complete. Reclamation and/or CSLC staff will report to SHPO and the consulting parties.

Timing: Mitigation will occur in the event of an archaeological discovery where avoidance is not feasible and would be ongoing over the construction timeframe.

Mitigation Measure CUL-1E (Alternative A): ***Avoid Soil Borrowing in the Vicinity of Known Archaeological Resources.*** Reclamation will design the Project soil borrowing

activities to avoid adverse effect on known archaeological resources, to the extent feasible. Known archaeological resources will be delineated and avoided during construction. Mitigation Measures CUL-1B, CUL-1C, and CUL-1D will also be implemented, as needed.

> **Implementation Action:** If feasible, Reclamation will design the Project soil borrowing activities to avoid any adverse effect on known archaeological resources, such as CA-FRA-45 and CA-FRA-106, both of which are considered potentially significant historical resources. (Mitigation Measures CUL-1B, CUL-1C, and CUL-1D will also be implemented, as needed.) At least 90-days prior to proposed borrowing activities, an archaeologist approved by Reclamation and/or CSLC staff will determine the extent of known resource near borrow areas through a presence or absence testing program using augers or test pits. The Project archaeologist will then cordon the site boundaries in a manner that restricts construction equipment or personnel from entering the site.
>
> **Location:** Within the vicinity of known archaeological resources, including CA-FRA-45 and CA-FRA-106.
>
> **Effectiveness Criteria:** Avoidance of areas within delineated site boundaries.
>
> **Responsible Agency:** Reclamation and CSLC.
>
> **Monitoring/Reporting Action:** Reclamation and/or CSLC staff will report to SHPO and the consulting parties.
>
> **Timing:** At least 90-days prior to proposed borrowing activities.

Implementation of Mitigation Measures CUL-1A, CUL-1B, CUL-1C, CUL-1D, and CUL-1E would decrease impacts on archaeological resources. Impacts after mitigation would be **less than significant** for Alternative A.

Impact CUL-2 (Alternative A): *Effects on Historic Properties Listed or Eligible for Listing in the National or California Register.* Under Alternative A, Mendota Dam and the DMC would not be modified by Project construction activities. Operations of Mendota Dam and DMC would be similar to the No-Action Alternative because these facilities are operated to make water deliveries which would not be affected by Alternative A.

Compared to existing conditions, these historic properties would remain unchanged. This alternative would have **no impact** to historic properties or historical resources of the built environment (architectural resources) that are listed or eligible for listing in the National or California Register.

Impact CUL-3 (Alternative A): *Effects on Cultural Resources during the Operations and Maintenance Phase of the Project.* Compared to the No-Action Alternative, the increased channel conveyance capacity, increased floodplain area, and floodplain and channel grading associated with Alternative A, in combination with flood flows and

Restoration Flows, could allow opportunities for new impacts to cultural resources (archaeological sites, historic-era structural resources, and traditional cultural properties/areas of concern). Alternative A would include a new levee system encompassing the river channel and additional floodplain areas that would typically have been disturbed by prior agricultural activities. Although there is a potential for increased erosion on the floodplain due to flood flows and Restoration Flows, velocities would decrease as water inundates more of the floodplain. Highly erodible areas would be reinforced by the Project (such as areas below concrete structures and at river bends) and water velocities and erosional forces are expected to be negligible in areas away from the main channel. Therefore, flood flows and Restoration Flows would not cause significant impacts to cultural resources in previously undisturbed areas that are located on the floodplain and outside of the main channel. Archaeological sites within and adjacent to the San Joaquin River would continue to be exposed to Friant Dam releases during ongoing operations, but higher flows would be distributed over the floodplain.

When comparing Alternative A to existing conditions, impacts to cultural resources on the floodplain would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative A to the No-Action Alternative). This impact would be **less than significant**.

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Key features of Alternative B include construction of a new levee system to establish a bypass channel to northeast of the existing river channel, Compact Bypass Bifurcation Structure, Mendota Pool Control Structure, and re-route of Drive 10 ½. No construction activities are proposed at or near Mendota Dam, which falls outside the Project boundary under Alternative B. Construction activity is expected to occur intermittently over an approximate 157-month timeframe.

Impact CUL-1 (Alternative B): ***Effects on Archaeological Resources from Ground Disturbing Activities during Construction.*** Refer to Impact CUL-1 (Alternative A). Potential impacts of Alternative B would be the same as potential impacts of Alternative A. This impact would be **potentially significant**.

Mitigation Measures CUL-1A, CUL-1B, CUL-1C, CUL-1D, and CUL-1E (Alternative B): ***Comply with Section 106 of the NHPA or Equivalent, Conduct Archaeological Monitoring in Proximity to Identified Sites or Areas of Sensitivity, Halt Work in the Event of an Archaeological Discovery, Plan an Intentional Site Burial Preservation in Place,*** **and** ***Avoid Soil Borrowing in the Vicinity of Known Archaeological Resources.*** Refer to Mitigation Measures CUL-1A, CUL-1B, CUL-1C, CUL-1D, and CUL-1E (Alternative A). The same measures would be used here. This impact would be **less than significant** after mitigation.

Impact CUL-2 (Alternative B): ***Effects to Historical Properties Listed or Eligible for Listing in the National or California Register.*** Refer to Impact CUL-3 (Alternative A). Potential impacts of Alternative B would be the same as potential impacts of Alternative A. There would be **no impact**.

Impact CUL-3 (Alternative B): ***Effects on Cultural Resources during the Operations and Maintenance Phase of the Project.*** Refer to Impact CUL-4 (Alternative A). Potential impacts of Alternative B would be the same as potential impacts of Alternative A. This impact would be **less than significant**.

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Key features of Alternative C include construction of new fish passage facilities at Mendota Dam, grade control structures downstream of Mendota Dam, a new Fresno Slough Dam, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 133-month timeframe.

Impact CUL-1 (Alternative C): ***Effects on Archaeological Resources from Ground Disturbing Activities during Construction.*** Refer to Impact CUL-1 (Alternative A). Potential impacts of Alternative C would be the same as potential impacts of Alternative A. This impact would be **potentially significant**.

Mitigation Measures CUL-1A, CUL-1B, CUL-1C, CUL-1D, and CUL-1E (Alternative C): ***Comply with Section 106 of the NHPA or Equivalent, Conduct Archaeological Monitoring in Proximity to Identified Sites or Areas of Sensitivity, Halt Work in the Event of an Archaeological Discovery, Plan an Intentional Site Burial Preservation in Place,*** **and** ***Avoid Soil Borrowing, or other Ground Disturbing Activity in the Vicinity of Known Archaeological Resources.*** Refer to Mitigation Measures CUL-1A, CUL-1B, CUL-1C, CUL-1D, and CUL-1E (Alternative A). The same measures would be used here. This impact would be **less than significant** after mitigation.

Impact CUL-2 (Alternative C): ***Effects to Historical Properties Listed or Eligible for Listing in the National or California Register.*** In comparison to the No-Action Alternative, Alternative C would include construction of a fish ladder at Mendota Dam and modification in Mendota Dam operations. This would cause physical changes to the Mendota Dam due to the addition of a fish ladder. Alternative C would also cause a small realignment to a section of the DMC where it transitions into Mendota Pool. An inlet canal is proposed at this transition location that would take water from the upstream side of the proposed Fresno Slough Dam, run north adjacent to the west side of the San Joaquin River, and connect to the Main Canal and Helm Ditch just west of their current intakes. This would cause only a minor physical change to the DMC. Because this alternative proposes physical changes to the Mendota Dam, which is eligible for listing as a historic property under Section 106 and is a historical resource listed in the California Register, a substantial adverse change or adverse effect could occur to this resource.

While the physical alterations of Mendota Dam required for the Project may not destroy the resource, it may change the resource such that it would no longer convey its significance; hence, this would be considered a substantial adverse change to the resource. While the significance of the resources is more related to its association with early irrigation public works in the Central Valley, rather than its architectural distinction, the alterations proposed may diminish the capacity of the resource to resemble its historic period of significance.

When comparing Alternative C to existing conditions, impacts to architectural resources would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative C to the No-Action Alternative). This would be a **potentially significant** impact.

Mitigation Measure CUL-2 (Alternative C): ***Follow the Secretary of the Interior's Standards for the Treatment of Historic Properties.*** Alterations to historical buildings or structures will conform to the *Secretary of the Interior's Standards for the Treatment of Historic Properties* (Weeks and Grimmer 1995). Where new structures are required as elements of improved fish passage, such as the new proposed fish ladder at Mendota Dam, designs that are compatible with the overall character of the historic property are preferred. This includes the continuation of the existing character through the use of materials as well as consistent use of color and placement which reduces overall visual effects. This mitigation measure would reduce impacts on significant historical buildings and structures to a **less-than-significant** level.

> **Implementation Action:** Alterations to historical buildings or structures would conform to the *Secretary of the Interior's Standards for the Treatment of Historic Properties* (Weeks and Grimmer 1995).
>
> **Location:** Construction activities at Mendota Dam.
>
> **Effectiveness Criteria:** Secretary of the Interior's Standards are met.
>
> **Responsible Agency:** Reclamation and CSLC.
>
> **Monitoring/Reporting Action:** Reclamation and/or CSLC staff will report to SHPO and the consulting parties.
>
> **Timing:** Prior to and during construction activities at Mendota Dam.

Impact CUL-3 (Alternative C): ***Effects on Cultural Resources during the Operations and Maintenance Phase of the Project.*** Refer to Impact CUL-4 (Alternative A). Potential impacts of Alternative C would be the same as potential impacts of Alternative A. This impact would be **less than significant**.

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Key features of Alternative D include construction of new fish passage facilities at Mendota Dam, grade control structures downstream of Mendota Dam, Fresno Slough Dam, Main Canal and Helm Ditch relocations, and the North Canal. Construction activity is expected to occur intermittently over an approximate 158-month timeframe.

Impact CUL-1 (Alternative D): ***Effects on Archaeological Resources from Ground Disturbing Activities during Construction.*** Refer to Impact CUL-1 (Alternative A). Potential impacts of Alternative D would be the same as potential impacts of Alternative A. This impact would be **potentially significant**.

Mitigation Measures CUL-1A, CUL-1B, CUL-1C, CUL-1D, and CUL-1E (Alternative D): ***Comply with Section 106 of the NHPA or Equivalent, Conduct Archaeological Monitoring in Proximity to Identified Sites or Areas of Sensitivity, Halt Work in the Event of an Archaeological Discovery, Plan an Intentional Site Burial Preservation in Place,*** **and** ***Avoid Soil Borrowing, or other Ground Disturbing Activity in the Vicinity of Known Archaeological Resources.*** Refer to Mitigation Measures CUL-1A, CUL-1B, CUL-1C, CUL-1D, and CUL-1E (Alternative A). The same measures would be used here. This impact would be **less than significant** after mitigation.

Impact CUL-2 (Alternative D): ***Effects to Historical Properties Listed or Eligible for Listing in the National or California Register.*** Refer to Impact CUL-3 (Alternative C). Because this alternative proposes changes to the Mendota Dam, a historic property under Section 106 and a historical resource listed in the California Register, this may cause substantial adverse change or adverse effects to this resource. This impact would be **potentially significant**.

Mitigation Measure CUL-2 (Alternative D): ***Follow the Secretary of the Interior's Standards for the Treatment of Historic Properties.*** Refer to Mitigation Measure CUL-2 (Alternative C). The same measure would be used here. This impact would be **less than significant** after mitigation.

Impact CUL-3 (Alternative D): ***Effects on Cultural Resources during the Operations and Maintenance Phase of the Project.*** Refer to Impact CUL-4 (Alternative A). Potential impacts of Alternative D would be the same as potential impacts of Alternative A. This impact would be **less than significant**.

10.0 Environmental Justice

Environmental justice is generally defined as:

> *"The fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. Fair treatment means that no group of people, including racial, ethnic, or socioeconomic group should bear a disproportionate share of the negative environmental consequences resulting from industrial, municipal, and commercial operations or the execution of federal, state, local, and tribal programs and policies" (U.S. Department of Energy 1997).*

The purpose of the environmental justice analysis is to determine whether disproportionately high and adverse environmental and economic effects would be realized by minority and/or low-income populations with implementation of projects, programs, or policies. To facilitate this analysis, information on the demographic and social characteristics of the population in the Project area has been collected to determine the extent to which minority and/or low-income populations exist in the region. This information is presented in Section 10.1. Section 10.2 presents the regulatory setting applicable to environmental justice. In Section 10.3, the anticipated environmental and socioeconomic impacts of the Project are assessed in the context of environmental justice populations of concern.

10.1 Environmental Setting

This section describes the demographic and socioeconomic characteristics of populations potentially affected by the Project, which serve as the foundation of the environmental justice analysis. The geographic area considered for the environmental justice analysis covers the two counties within which Reach 2B is located (i.e., Fresno and Madera counties, hereinafter referred to as the two-county region). It also includes the three census tracts (CT) in proximity to Reach 2B (i.e., CT 39, CT 83.01, and CT 4). The location of these census tracts are shown on Figure 10-1.

Environmental justice focuses on minority and low-income populations, and therefore topics addressed include race and ethnicity and relevant economic indicators of social well-being, including income and poverty. In addition, based on the strong connection between the Project area and the agricultural industry, information on these environmental justice parameters is also presented for local agricultural workforce.

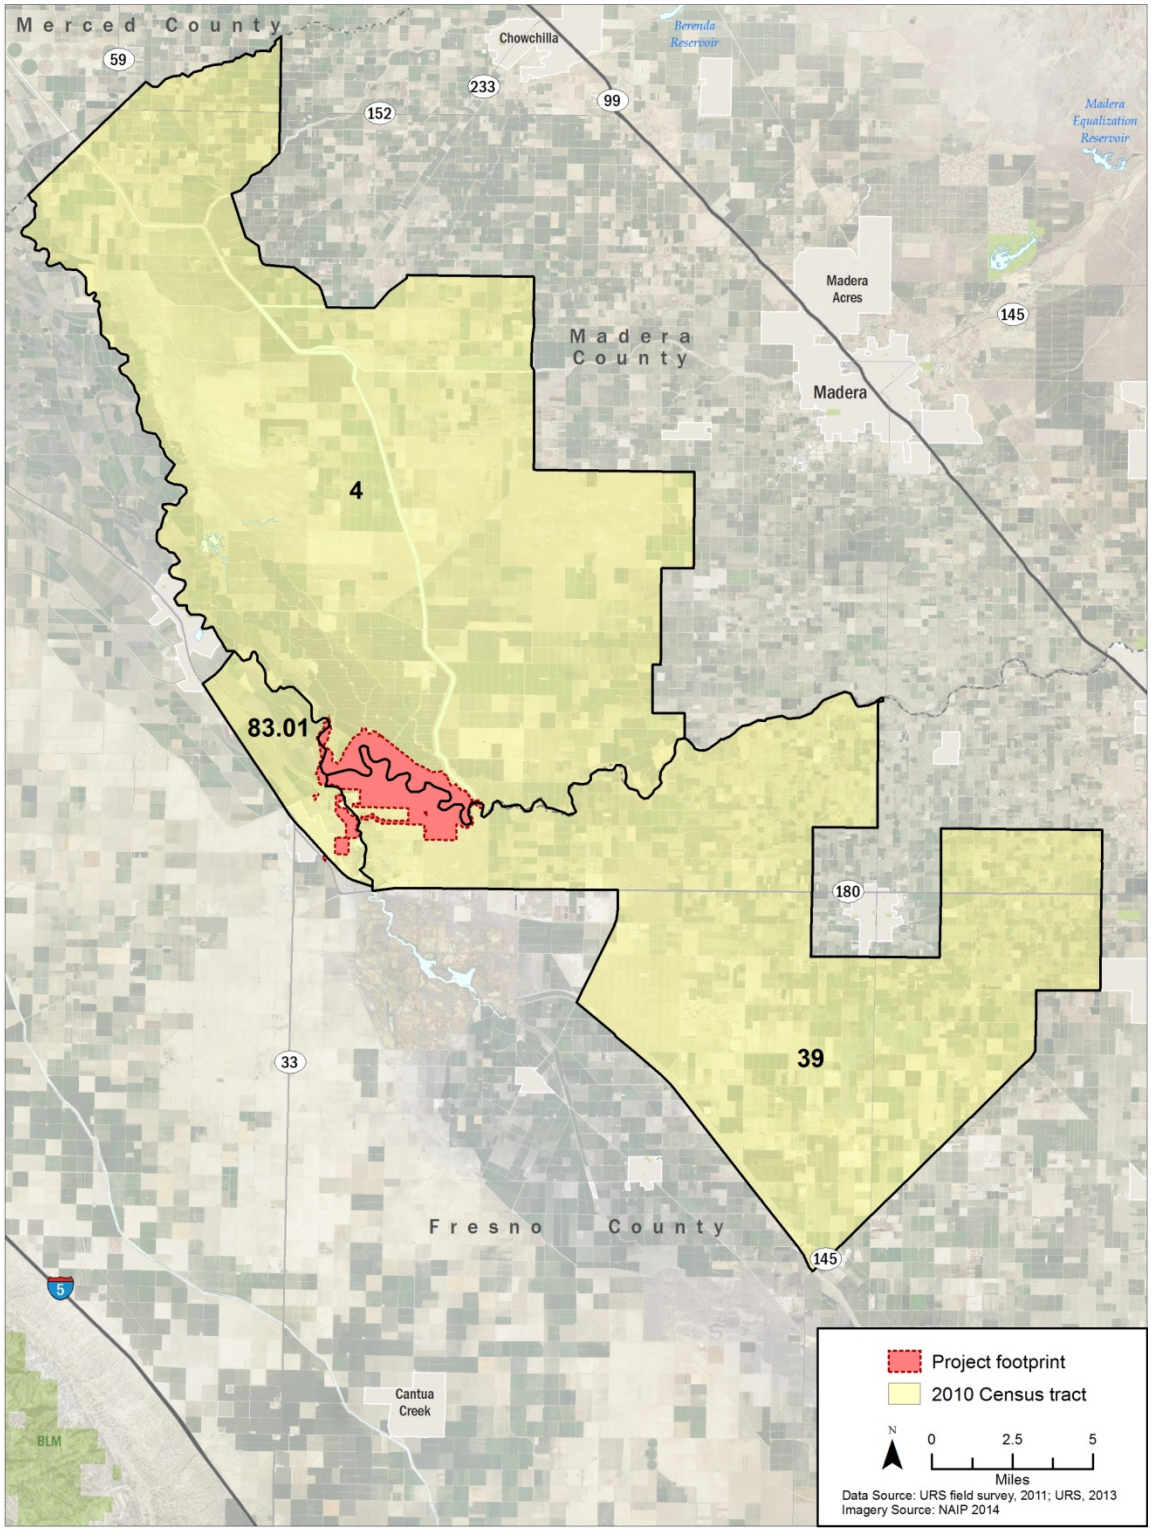

Figure 10-1.
Census Tracts near Reach 2B

The social and demographic characteristics of the Project area were evaluated to determine if any environmental justice communities of concern exist locally. This is determined based on the comparison of select social and demographic parameters for the Project area relative to the State, which serves as the reference population. If the minority or low-income populations are "meaningfully greater" in the region relative to this reference population, or where the proportion exceeds 50 percent of the total population, then an environmental justice community of concern is assumed to be present.

10.1.1 Social and Demographic Characteristics

Race and Ethnicity (Minority Populations)

The Council on Environmental Quality (CEQ 1997) defines a minority as persons who identify themselves as *Black/African American*, *Asian*, *Native Hawaiian or Other Pacific Islander*, and *American Indian or Alaska Native*. For the purposes of this analysis, the definition of minority also extends to other nonwhite categories of race, which include *Some Other Race* and *Two or More Races*. The CEQ guidance also identifies persons of *Hispanic* ethnicity, regardless of race, as part of minority populations (CEQ 1997). Hispanic origin is considered to be an ethnic category separate from race, according to the U.S. Census. These definitions apply here even though the minority populations within the State when combined are greater than 50 percent (as shown in Table 10-1 below).

Table 10-1 displays the potentially affected minority groups within the Project area based on the most recent decennial census data from the U.S. Census Bureau. The category "total minority" includes all residents except non-Hispanic whites, who are not considered minorities. As shown, the State and both Fresno and Madera counties have a minority population exceeding 50 percent. Together, the two-county region contains a minority population of 66.5 percent. The three CTs within the Project area also exceed 50 percent, with a joint minority population of 83.3 percent. In fact, CT 83.01 in Fresno County has an exceptionally high proportion of minorities (97.7 percent). Further, the CTs and two-county region both have a higher minority population compared to the State. These data suggest that the Project area and vicinity is considered an environmental justice community of concern from the perspective of race and ethnicity.

Table 10-2 presents the racial and ethnic composition of farm operators within the two-county region and State based on the most recent census of agriculture from the U.S. Department of Agriculture. Information on the race and ethnicity of farm operators at the CT level is not available. The farm operator is the person who runs the farm, making the day-to-day management decisions. The operator could be an owner, hired manager, cash tenant, share tenant, and/or a partner. As shown, the majority of farm operators in the two-county region are white (69.3 percent), which is representative of patterns in the State as a whole. There are slightly higher proportions of farm operators identifying as Asian and Hispanics in the two-county region compared to the State.

Table 10-1.
Race and Ethnicity of Local Population, 2010

Geo-graphic Area	Total Population	Race							Hispanic Origin		Total Minority [b]
		White	Black or African-American	American Indian	Asian	Native Hawaiian/ Pacific Islander	Some Other Race	Two or More Races	White Alone, Non-Hispanic	All Races, Hispanic [a]	
Fresno County	930,450	515,145	49,523	15,649	89,357	1,405	217,085	42,286	304,522	468,070	625,928

Source: U.S. Census Bureau 2010

Notes:

[a] The term "Hispanic" is an ethnic category and can apply to members of any race, including respondents who self-identified as "white." The total numbers of Hispanic residents for each geographic region are tabulated separately from the racial distribution by the U.S. Census Bureau. Hispanic information is taken from U.S. Census Bureau 2010, while data regarding race are taken from U.S. Census Bureau 2010, Table P7.

[b] "Total minority" is the aggregation of all non-white racial groups with the addition of all Hispanics, regardless of race. Total minority information is taken from U.S. Census Bureau 2010, with the total for "Not Hispanic or Latino: White alone" subtracted from the total population.

Key: % = percent, CT = Census Tract

Table 10-2.
Race and Ethnicity of Farm Operators, 2012

Geo-graphic Area	Total Farm Operators	White	Black or African-American	American Indian	Asian	Native Hawaiian / Pacific Islander	More Than One Race	All Race, Hispanic

Source: USDA 2014, Census of Agriculture

Notes:

"Total Minority" cannot be computed from the data provided by the U.S. Department of Agriculture (USDA) Agricultural Census, as a tabulation of "White Alone, Non-Hispanic" farm operators is not provided.

Key:

% = percent

USDA = U.S. Department of Agriculture

Table 10-3 presents the racial and ethnic composition of laborers and helpers within the Project area based on the most recent Equal Employment Opportunity Tabulation data from the U.S. Census. Information on the race and ethnicity of laborers and helpers at the CT level is not available. The category "laborers and helpers" generally includes farm laborers, but may also include other manual labor sectors as part of the total. This category excludes construction personnel, which are captured under a different category by the U.S. Census Bureau. As shown, Hispanics comprise the largest proportion of laborers in each geographic area. The proportion of Hispanic laborers and helpers in the two-county region (86.4 percent) is higher to that in the State (71.3 percent). A similar pattern is found when evaluating all minority groups. The proportion of total minorities in this component of the workforce is 90.9 percent in the two-county region compared to 80.8 percent in the State.

Socioeconomic Indicators of Well-Being (Low-Income Populations)

For this analysis, persons with income below the poverty threshold established by the U.S. Census Bureau are considered low-income populations. Table 10-4 presents the median household income, per capita income, and proportion of individuals living below the poverty threshold for the Project area based on the most recent American Community Survey 5-year estimate from the U.S. Census Bureau. Any poverty rate which is at least double the statewide poverty rate is considered meaningfully greater for the purposes of this environmental justice analysis.

Table 10-3.
Race and Ethnicity of Laborers and Helpers, 2006-2010 Estimate

Geographic Area	Total Laborers and Helpers	Race (Not Hispanic or Latino)							All Race, Hispanic [a]	Total Minority [b]
		White	Black or African-American	American Indian	Asian	Native Hawaiian/ Pacific Islander	Some Other Race	Two or More Races		
Fresno County	46,120	4,085	580	130	1,160	0	295	160	39,710	42,035
	100.0%	8.9%	1.3%	0.3%	2.5%	0.0%	0.6%	0.4%	86.1%	91.2%
Madera County	10,145	1,045	100	10	40	0	10	34	8,905	9,099
	100.0%	10.3%	1.0%	0.1%	0.4%	0.0%	0.1%	0.3%	86.1%	88.0%
Two-county Region	56,265	5,130	680	140	1,200	0	305	194	48,615	51,134

California	870,025	167,320	29,900	3,085	34,505	3,205	4,765	6,985	620,260	702,705
	100.0%	19.2%	3.4%	0.4%	4.0%	0.4%	0.5%	0.8%	71.3%	80.8%

Source: U.S. Census Bureau 2012 (EEO Tabulation 2006-2010)

Notes:

[a] The term "Hispanic" is an ethnic category and can apply to members of any race, including respondents who self-identified as "white."

[b] "Total minority" is the aggregation of all non-white racial groups with the addition of all Hispanics, regardless of race.

Key:

% = percent

Table 10-4.
Income and Poverty, 2008-2012 Estimate

Geographic Area	Median Household Income	Per Capita Income	Population Below Poverty Threshold	
Fresno County	$45,741	$20,391	230,768	24.8%
CT 39	$34,135	$15,630	1,436	31.2%
CT 83.01	$34,607	$10,282	2,007	33.4%
Madera County	$47,937	$18,474	31,780	21.1%
CT 4	$33,750	$18,247	183	16.8%
Total CT's[1]	$34,164	$14,720	3,627	27.7%
Two-County Region[1]	$46,839	$19,433	262,548	24.3%
State of California	$61,400	$29,551	5,710,735	15.3%

Source: U.S. Census Bureau 2013, 2008-2012 American Community Survey 5-year estimates

Notes:

[1] Poverty rates calculated based on weighted population (relative to the percent population of each CT in the Total CT's and relative to the percent population of each county in the Two-County Region)

Key: % = percent

Overall, the two-county region contains a greater percentage of people living in poverty relative to the State (24.3 percent versus 15.3 percent, respectively); this does not exceed the threshold for this analysis. However, CT 39 and CT 83.01 in Fresno County have a meaningfully-greater proportion of people living below the poverty threshold at 31.2 percent and 33.4 percent, respectively. These data suggest that the Project area and vicinity is considered an environmental justice community of concern from the perspective of socioeconomic indicators.

Table 10-5 presents median annual wage information for farm-related occupations within the Project area based on recent data from the California Employment Development Department. As shown, the median wage for all farm-related occupations is $19,504 in Fresno County and $19,416 in Madera County. Both figures are less than the county-wide median wage for all industries ($41,852 and $43,956, respectively) and median wage earnings across the State ($52,630). All categories of agricultural workers earn less than the statewide average except for graders and sorters.[1] The information presented in Table 10-5 shows that median incomes in the farming industry are lower than the median income for all industries, with some less-skilled agricultural workers earning substantially less than regional averages.

[1] Comparable data for Agricultural Inspectors, Graders and Sorters, and Agricultural Workers, Other for Madera County were not available.

Table 10-5.
Agricultural Workers Median Annual Wages, 2012 (1st Quarter)

Geographic Area	Farming, Fishing, and Forestry Occupations-Overall	First-Line Supervisors	Agricultural Inspectors	Graders and Sorters	Equipment Operators	Farmworker (Crop, Nursery, Greenhouse)	Farmworker (Farm and Ranch Animals)	Agricultural Workers, Other	Median Wage, All Industries
Fresno County	$19,504	$31,512	$41,275	$19,847	$19,836	$18,821	$21,368	$38,584	$41,852
Madera County	$19,416	$30,158	$23,755	--	$22,064	$18,639	$20,249	--	$43,956
California	$20,944	$43,598	$47,283	$19,594	$24,150	$19,551	$25,672	$28,725	$52,630

-- = data not available

10.1.2 Long-term Challenges for Agricultural Lands

Future water demand in the Central Valley is affected by a number of growth and land use factors, including population growth, planting decisions by farmers, and size and type of urban landscapes. Future population growth and development density will determine the extent of the urban landscape and encroachment into agricultural lands. The *California Water Plan* (Department of Water Resources 2013) has evaluated several growth and climate change scenarios and predicts an increase in urban water demand associated with increased population growth, a decrease in agricultural water demand due to a reduction in irrigated crop acreage (and due to an increase in water conservation measures for agriculture), and a decrease in agricultural supply reliability in the Central Valley. The Central Valley could experience increased fallowing of agricultural lands and an associated decrease in farm-related occupations, which could affect environmental justice communities. How these trends would apply specifically to Reach 2B is unknown.

10.2 Regulatory Setting

This section describes the Federal, State, regional, and local regulatory setting related to environmental justice.

10.2.1 Federal

Federal laws and regulations pertaining to environmental justice in the Project area are summarized briefly below.

Executive Order 12898

In 1994, President Clinton issued Executive Order (EO) 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations (1994)*. EO 12898 requires each Federal agency to achieve environmental justice as part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects, including social or economic effects, of programs, policies, and activities on minority and low-income populations of the United States.

Council on Environmental Quality Guidance

The CEQ prepared *Environmental Justice Guidance under the National Environmental Policy Act* to assist Federal agencies in meeting their environmental justice commitments under the National Environmental Policy Act (NEPA). This guidance provides the following definition of the terms “minority” and “low income community” in the context of environmental justice analysis. Minority individuals are members of the following population groups: American Indian or Alaskan Native, Asian or Pacific Islanders, Black, and Hispanic. A low income community is one found to be below the poverty thresholds from the U.S. Census Bureau. CEQ has oversight for the Federal government’s compliance with EO 12898 and NEPA process, with the U.S. Environmental Protection Agency (EPA) serving as the lead agency responsible for implementation of the EO.

Environmental Compliance Memoranda No. ECM 95-3

The U.S. Department of the Interior, Office of Environmental Policy and Compliance (1995) confirms the requirement of EO 12898 for the U.S. Department of the Interior to consider impacts on minority and low-income populations and communities. A letter responding to an earlier request by the Secretary of the Interior states, "[H]enceforth, all environmental documents should specifically analyze and evaluate the impacts of any proposed projects, actions or decisions on minority and low-income populations and communities, as well as the equity of the distribution of the benefits and risks of those decisions."

10.2.2 State of California

State laws and regulations pertaining to environmental justice are discussed below.

Senate Bill 115

California was the first state to define environmental justice with Senate Bill (SB) 115. The bill defines environmental justice as "the fair treatment of people of all races, cultures and income with respect to development, adoption and implementation of environmental laws, regulations and policies." SB 115 added this language to California Government Code section 65040.12 and to Division 34 of the Public Resources Code relating to environmental quality. It also established the Governor's Office of Planning and Research as the coordinating agency for State programs and requested that the California Environmental Protection Agency (Cal/EPA) establish a model environmental justice policy for its boards, departments, and offices (California Resources Agency, undated).

California State Lands Commission Environmental Justice Policy

The California State Lands Commission (CSLC) pledges though its environmental justice policy to continue and enhance its processes, decisions, and programs with environmental justice as an essential consideration. It defines "environmental justice" in a manner consistent with the State as "the fair treatment of people of all races, cultures and income with respect to the development, adoption, implementation, and enforcement of environmental laws, regulations, and policies." This definition is consistent with the Public Trust Doctrine principle that the management of trust lands is for the benefit of all of the people. The purpose of the environmental justice policy is to ensure that environmental justice is an essential consideration in the CSLC's processes, decisions and programs and that all people who live in California have a meaningful way to participate in these activities. Implementation of CSLC's environmental justice policy is similar to implementation of environmental justice under the NEPA process.

10.2.3 Regional and Local

There are no known regional or local plans or policies related to environmental justice.

10.3 Environmental Consequences and Mitigation Measures

10.3.1 Impact Assessment Methodology

This section describes the approach used to conduct the assessment of potential effects related to environmental justice. This assessment utilizes information on the demographic and social characteristics of the Project area to determine whether there are minority or low-income populations that could be disproportionately and adversely affected by the Project alternatives. The identification of minority and low-income populations in the Project area is based on a comparison of select social and demographic characteristics, including race, per capita income and poverty rates, of communities that would be affected by the Project (e.g., city of Mendota) with a reference population (the State). Minority or low-income populations in the Project area that are meaningfully greater in proportion than in the reference population are considered environmental justice populations of concern.

The minority and low-income populations prevalent in the Project area have been evaluated in the context of the potential for adverse socioeconomic and environmental effects of the Project to determine if they would be disproportionately affected. The evaluation of environmental justice effects on minority and low-income populations considers the magnitude and timing of economic and environmental impacts and the nexus between such impacts and the affected populations, including their extent of use of affected resources, such as resources that support subsistence living.

10.3.2 Disproportionately High and Adverse Criteria

Under NEPA, an analysis of environmental justice effects is required; however, there is no standard set of criteria for evaluating environmental justice impacts. Under the California Environmental Quality Act (CEQA), economic and social impacts are not considered significant effects on the environment; therefore, there is no guidance on assessing environmental justice effects in the State CEQA Guidelines Appendix G. For this analysis, the Project would result in an environmental justice impact if it would result in any of the following:

- An impact on the natural or physical environment that substantially and adversely affects a minority population, low-income population, or Indian tribe disproportionately relative to the general population. Such effects may include ecological, cultural, and human health impacts from environmental hazards.
- An economic or social impact on the human environment that substantially and adversely affects a minority population, low-income population, or Indian tribe disproportionately relative to the general population. Such effects may include reductions in income and employment opportunities.
- Physical impacts on resources, such as fish and wildlife, which are used for subsistence consumption.

If an impact remains significant after all mitigation is implemented, then the impact is included in the environmental justice analysis, and the equity of the impact across the Project area population is determined. In instances where the location of the impact could

be described, the demographic characteristics of the surrounding area were assessed to determine whether a minority or low-income population meaningfully greater than the proportion of minority and/or low-income residents in the general population was present. “Meaningfully greater” populations were interpreted to be either 50 percent of the total population of the geographic unit or simply “greater” than any other population group within the surrounding, larger geography (which provides for a more conservative analysis). Otherwise, the environmental justice analysis is evaluated at a broader, more regional scale. Potentially significant and unavoidable impacts and significant and unavoidable impacts are identified in other chapters of this Environmental Impact Statement/Report (EIS/R).

10.3.3 Impacts and Mitigation Measures

This section describes a project-level evaluation of potential impacts to environmental justice communities of concern in the Project area from impacts on the natural or physical environment (ecological, cultural, and human health impacts). The primary impacts of the Project alternatives that factor in the environmental justice analysis are associated with removing agricultural lands from production and Project construction and operations expenditures, which affect socioeconomic conditions throughout the regional economy. This section includes analyses of potential effects relative to No-Action conditions in accordance with NEPA. This methodology will serve to address the State policies explained in Section 10.2.2. The analysis is organized by Project alternative with specific impact topics numbered sequentially under each alternative. With respect to environmental justice, the relevant issues and concerns are:

1. Effects on Environmental Justice Communities of Concern from Removal of Land from Agricultural Production.
2. Effects on Environmental Justice Communities of Concern from Changes in Regional Activity Attributed to Agricultural Production.
3. Effects on Environmental Justice Communities of Concern from Changes in Regional Activity Attributed to Project Construction and Operations.
4. Effects on Environmental Justice Communities of Concern from Conversion of Designated Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts.
5. Effects on Environmental Justice Communities of Concern due to Conflicts with Adopted Land Use Plans, Goals, Policies, and Ordinances
6. Effects on Environmental Justice Communities of Concern from Construction-Related Emissions of Criteria Air Pollutants and Precursors and Exposure of Sensitive Receptors to Substantial Concentrations of Toxic Air Contaminants.
7. Effects on Environmental Justice Communities of Concern from Physical Impacts on Resources Used for Subsistence Consumption (Fish and Wildlife).
8. Effects on Environmental Justice Communities of Concern from Inadequate or Reduced Emergency Access

There are other environmental justice-related issues covered in the Program Environmental Impact Statement/Report (PEIS/R) that are not covered here because they are not relevant to the Project area.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. However, other proposed actions under the San Joaquin River Restoration Program (SJRRP) would be implemented, including habitat restoration, augmentation of river flows, and reintroduction of salmon. Without the Project in Reach 2B, however, these activities would not achieve the Settlement goals. The analysis of environmental justice effects of the No-Action Alternative is based on a comparison to existing conditions.

Impact EJ-1 (No-Action Alternative): *Effects on Environmental Justice Communities of Concern from Removal of Land from Agricultural Production*. Under the No-Action Alternative, there would not be any land removed from agricultural production to accommodate the Project. Therefore, compared to existing conditions, a substantial decrease in the quantity of agricultural lands in the Project area would be unlikely, the No-Action Alternative would result in continued agricultural production, and local agricultural operations would continue to employ farm laborers and provide labor income to these workers, who are typically of Hispanic origin and generally part of the low-income population in the region. Disproportionately high and adverse effects on minority and low-income populations **would not occur** under the No-Action Alternative.

Impact EJ-2 (No-Action Alternative): *Effects on Environmental Justice Communities of Concern from Changes in Regional Activity Attributed to Agricultural Production*. As described in Impact EJ-1 (No-Action Alternative), there would likely be little to no land removed from agricultural production under the No-Action Alternative. Therefore, compared to existing conditions, there would be no change and local farms would continue to make expenditures in the local economy to support their operations, thereby generating economic benefits throughout Fresno and Madera counties, as measured by economic output, labor income, and jobs. Some of these regional benefits would accrue to minority and low-income populations residing in the two-county region. Disproportionately high and adverse effects on minority and low-income populations **would not occur** under the No-Action Alternative.

Impact EJ-3 (No-Action Alternative): *Effects on Environmental Justice Communities of Concern from Changes in Regional Activity Attributed to Project Construction and Operations*. Under the No-Action Alternative, the Project would not be implemented and there would not be any construction- and operations-related expenditures or employment supported by the Project that would generate economic benefits in the two-county region. There would be no change compared to existing conditions. Disproportionately high and adverse effects on minority and low-income populations **would not occur** under the No-Action Alternative.

Impact EJ-4 (No-Action Alternative): *Effects on Environmental Justice Communities of Concern from Conversion of Designated Farmland to Nonagricultural Uses and*

Cancellation of Williamson Act Contracts. Under the No-Action Alternative, the Project would not be implemented and there would not be any Project-related conversion of designated farmland to non-agricultural uses or cancellation of Williamson Act contracts that would affect agricultural workers which are disproportionately racial and/or ethnic minorities relative to State demographics. There would be no change compared to existing conditions as a result of Project-related activities. Therefore, disproportionately high and adverse effects on minority and low-income populations **would not occur** under the No-Action Alternative.

Impact EJ-5 (No-Action Alternative): ***Effects on Environmental Justice Communities of Concern due to Conflicts with Adopted Land Use Plans, Goals, Policies, and Ordinances.*** Under the No-Action Alternative, the Project would not be implemented and there would not be Project-related conflicts with adopted land use plans, goals, policies, and ordinances that would affect agricultural workers, which are disproportionately racial and/or ethnic minorities relative to State demographics. Therefore, disproportionately high and adverse effects on minority and low-income populations **would not occur** under the No-Action Alternative.

Impact EJ-6 (No-Action Alternative): ***Effects on Environmental Justice Communities of Concern from Construction-related Emissions of Criteria Air Pollutants and Precursors and Exposure of Sensitive Receptors to Substantial Concentrations of Toxic Air Contaminants.*** Under the No-Action Alternative, the existing regulatory framework would likely minimize adverse effects from emission of criteria air pollutants and precursors in localized areas. Local regulations that require dust abatement and criteria pollutant emissions reduction during construction are expected to reduce these impacts. However, there could be residual significant and unavoidable impacts from construction activities within the San Joaquin Valley Air Basin (SJVAB) that are unrelated to the Project, and regional effects could disproportionately affect low-income groups. If the SJVAB remains in nonattainment status for criteria air pollutants, then health impacts associated with poor air quality could affect low-income residents with less access to health care. Disproportionately high and adverse effects on minority and low-income populations **could occur**.

Impact EJ-7 (No-Action Alternative): ***Effects on Environmental Justice Communities of Concern from Physical Impacts on Resources Used for Subsistence Consumption (Fish and Wildlife).*** Under the No-Action Alternative, the Project would not be implemented and there would not be any Project-related physical changes on resources that would affect subsistence consumers which are disproportionately racial and/or ethnic minorities relative to State demographics. There would be no change compared to existing conditions as a result of Project-related activities. Therefore, disproportionately high and adverse effects on minority and low-income populations **would not occur** under the No-Action Alternative.

Impact EJ-8 (No-Action Alternative): ***Effects on Environmental Justice Communities of Concern from Reduced Inadequate or Emergency Access.*** Under the No-Action Alternative, the Project would not be implemented and there would not be changes in emergency access that would affect agricultural workers, which are disproportionately

racial and/or ethnic minorities relative to State demographics. Therefore, disproportionately high and adverse effects on minority and low-income populations **would not occur** under the No-Action Alternative.

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

All of the Project alternatives, including Alternative A, would entail habitat restoration activities in conjunction with an expanded floodplain and widened levee alignment, as well as new Project facilities that promote fish passage through Reach 2B. The Project would result in adverse impacts on agricultural resources (refer to Chapter 16, "Land Use Planning and Agricultural Resources") and generate both socioeconomic impacts associated with losses in agricultural production and benefits attributed to construction and operations spending (refer to Chapter 21, "Socioeconomics and Economics").

Impact EJ-1 (Alternative A): ***Effects on Environmental Justice Communities of Concern from Removal of Land from Agricultural Production*****.** Compared to No-Action, Alternative A would permanently remove approximately 1,180 acres of agricultural land from production and 580 acres of cropland would likely be shifted to livestock grazing. Additional agricultural land would also be temporarily taken out of production affected during the multi-year construction period. Under Alternative A, termination of agricultural production on lands within the Project area would result in lower demand for farm labor. It is anticipated that 40 farm-level jobs and $1.8 million in annual labor income would be permanently lost when agricultural land is removed from production under Alternative A; temporary effects during construction are relatively minor. As described above, the agricultural labor force predominantly consists of workers of Hispanic origin with relatively low incomes. As a result, the adverse effects on local agricultural operations would be realized by an environmental justice community of concern in the Project area. Therefore, disproportionately high and adverse effects on minority and low-income populations **could occur** under Alternative A.

Impact EJ-2 (Alternative A): ***Effects on Environmental Justice Communities of Concern from Changes in Regional Activity Attributed to Agricultural Production*****.** Compared to No-Action, Alternative A would result in a decline in regional economic activity in the two-county region, namely losses in economic output (or production), labor income and jobs, in conjunction with decreased agricultural production in the Project area. Considering the inter-industry linkages between the agricultural sector and other sectors of the regional economy (i.e., "ripple" or multiplier effects), the total economic impacts in Fresno and Madera counties attributed to decreased agricultural production in the Project area include annual losses of 75 jobs and $3.1 million in labor income over the long term under Alternative A. While the direct economic impacts would primarily occur in the agricultural sector, as described in Impact EJ-1 (Alternative A), the regional economic impacts would be more widespread, affecting a range of industries, including agricultural-support and other businesses linked to agriculture. As such, the regional economic impacts would affect a cross-section of the local population, which has a relatively high proportion of minority and low-income residents. However, it is difficult to predict the extent to which these adverse effects would be realized by minority and/or low-income populations living in the region. As a result of impacts on regional

economic conditions, disproportionately high and adverse effects on minority and low-income populations in the region **could occur** under Alternative A.

Impact EJ-3 (Alternative A): ***Effects on Environmental Justice Communities of Concern from Changes in Regional Activity Attributed to Project Construction and Operations.*** Compared to No-Action, Alternative A would benefit the regional economy based on construction and operations expenditures that would generate increases in economic output, labor income and jobs based on inter-industry linkages among affected sectors in the economy. Within the two-county region, construction activity is expected to support a total of approximately 293 jobs and $19.7 million in labor income annually over the construction period under Alternative A. Over the long term, operations expenditures would support about $705,000 in labor income annually and 14 jobs in the region. The direct short-and long-term economic benefits would primarily occur in construction-related sectors, while the regional economic benefits would affect a wide range of industries. Accordingly, the increase in economic activity would benefit a cross-section of the local population, which is characterized by a relatively-high proportion of minority and low-income residents as described above. However, it is difficult to predict the extent to which these beneficial employment and income effects would be realized by minority and/or low-income populations living in the region. Disproportionately high and adverse effects on minority and low-income populations **would not occur** under Alternative A.

Impact EJ-4 (Alternative A): ***Effects on Environmental Justice Communities of Concern from Conversion of Designated Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts.*** Proposed land use conversions associated with Alternative A would be inconsistent with local policies that call for the agricultural productivity of designated Farmland to be preserved and Williamson Act contracts to be maintained to the extent possible. The conversion of designated Farmland and cancellation of Williamson Act contracts could occur in the Project area. This significant and unavoidable impact is not expected to disproportionately affect specific geographic concentrations of low-income populations or minority groups because the effects would be distributed. However, the agricultural workers affected by reduced acreage of farmland are disproportionately racial and/or ethnic minorities relative to State demographics. The percentage of low-income agricultural workers who work in this area is also high. Therefore, disproportionately high and adverse effects on minority and low-income populations **could occur** under Alternative A.

Impact EJ-5 (Alternative A): ***Effects on Environmental Justice Communities of Concern due to Conflicts with Adopted Land Use Plans, Goals, Policies, and Ordinances.*** Proposed land use conversion in the Project area would conflict with adopted land use plans, goals, policies, and ordinances of affected jurisdictions. To recognize and minimize adverse effects on agricultural land use and zoning, Project proponents would notify Fresno and Madera County planning agencies of inconsistencies in designations and applicable polices for the affected areas. The population affected by land use conversion includes only one or two residences, which is too few for a disproportionately high and adverse effect. Therefore, disproportionately high and adverse effects on minority and low-income populations **would not occur**.

Impact EJ-6 (Alternative A): ***Effects on Environmental Justice Communities of Concern from Construction-related Emissions of Criteria Air Pollutants and Precursors and Exposure of Sensitive Receptors to Substantial Concentrations of Toxic Air Contaminants.*** The existing regulatory framework would minimize adverse effects from emission of criteria air pollutants and precursors near the Project area. However, there could be residual significant and unavoidable impacts from construction activities within the SJVAB, and regional and local effects could disproportionately affect low-income groups. If the SJVAB remains in nonattainment status for criteria air pollutants, then health impacts associated with poor air quality could regionally affect low-income residents with less access to health care. Project-related construction could affect local minority and low-income sensitive receptors. Disproportionately high and adverse effects on minority and low-income populations **could occur**.

Impact EJ-7 (Alternative A): ***Effects on Environmental Justice Communities of Concern from Physical Impacts on Resources Used for Subsistence Consumption (Fish and Wildlife).*** In Reach 2B, the primary resource for subsistence consumption is fishing in Mendota Pool and the river just downstream of Mendota Dam. Alternative A would not make physical changes to the portion of Mendota Pool that is publically accessible and typically used for fishing opportunities. Compared to the No-Action Alternative, the effects of Alternative A would be the same. Therefore, disproportionately high and adverse effects on minority and low-income populations **would not occur** under Alternative A.

Impact EJ-8 (Alternative A): ***Effects on Environmental Justice Communities of Concern from Inadequate or Reduced Emergency Access.*** Project alternatives would create temporary or permanent roadway discontinuities at Drive 10 ½ and/or the San Mateo Avenue crossing that could reduce emergency response times to private property north of the river. The potentially affected population includes residences and agricultural workers. Agricultural workers would be able to flee potential dangers such as brush fires and use alternative evacuation routes. Response times to residences north of the river near the crossings could be affected; however, the number of residences is too few for a disproportionately high and adverse effect. Therefore, disproportionately high and adverse effects on minority and low-income populations **would not occur**.

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Alternative B proposes habitat restoration activities in conjunction with an expanded floodplain and widened levee alignment, as well as new Project facilities that promote fish passage through Reach 2B. The Project would result in adverse impacts on agricultural resources (refer to Chapter 16, "Land Use Planning and Agricultural Resources") and generate both socioeconomic impacts associated with losses in agricultural production and benefits attributed to construction and operations spending (refer to Chapter 21, "Socioeconomics and Economics").

Impact EJ-1 (Alternative B): ***Effects on Environmental Justice Communities of Concern from Removal of Land from Agricultural Production.*** Alternative B would generally have similar effects on environmental justice communities of concern as

described for Alternative A; refer to Impact EJ-1 (Alternative A) for more details. Compared to No-Action, Alternative B would permanently remove approximately 1,032 acres of agricultural land from production, and additional agricultural land would also be temporarily taken out of production affected during the multi-year construction period. In the context of environmental justice, it is anticipated that approximately 46 farm-level jobs and $2.1 million in annual labor income would be permanently lost under Alternative B, which would be realized predominantly by Hispanic workers characterized by low income levels. Therefore, disproportionately high and adverse effects on minority and low-income populations **could occur** under Alternative B.

Impact EJ-2 (Alternative B): ***Effects on Environmental Justice Communities of Concern from Changes in Regional Activity Attributed to Agricultural Production.*** Alternative B would have similar effects on environmental justice communities of concern as described for Alternative A; refer to Impact EJ-2 (Alternative A) for more details. Compared to No-Action, Alternative B would adversely affect the regional economy based on reductions in agricultural production in the Project area. Agricultural production losses under Alternative B would result in total losses of 93 jobs and $3.8 million annually over the long term throughout Fresno and Madera counties, which are characterized by relatively large numbers of minority and/or low-income populations; therefore, the regional economic impacts anticipated with the Project could adversely affect minority and/or low-income populations residing in the region. As a result, disproportionately high and adverse effects on minority and low-income populations **could occur** under Alternative B.

Impact EJ-3 (Alternative B): ***Effects on Environmental Justice Communities of Concern from Changes in Regional Activity Attributed to Project Construction and Operations.*** Alternative B would have similar effects on environmental justice communities of concern as described for Alternative A; refer to Impact EJ-3 (Alternative A) for more details. Compared to No-Action, Alternative B would generate regional economic benefits based on new spending on construction and operations activities associated with the Project. Within the two-county region, construction activity is expected to support a total of approximately 244 jobs and $16.1 million in labor income annually over the construction period. In addition, operations expenditures would support about $600,000 in labor income annually and 12 jobs over the long term. The regional economic benefits of Project construction and operations anticipated under Alternative B would benefit local residents in Fresno and Madera counties, which are characterized by relatively large numbers of minority and/or low-income populations. As a result, disproportionately high and adverse effects on minority and low-income populations **would not occur** under Alternative B.

Impact EJ-4 (Alternative B): ***Effects on Environmental Justice Communities of Concern from Conversion of Designated Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts.*** This analysis and conclusion is the same as Impact EJ-4 (Alternative A). The conversion of designated Farmland and cancellation of Williamson Act contracts would occur in the Project area and agricultural workers affected by the reduced acreage of farmland are disproportionately racial and/or ethnic

minorities relative to State demographics. Disproportionately high and adverse effects on minority and low-income populations **could occur** under Alternative B.

Impact EJ-5 (Alternative B): *Effects on Environmental Justice Communities of Concern due to Conflicts with Adopted Land Use Plans, Goals, Policies, and Ordinances.* Alternative B would have similar effects on environmental justice communities of concern as described for Alternative A; refer to Impact EJ-5 (Alternative A) for more details. Disproportionately high and adverse effects on minority and low-income populations **would not occur**.

Impact EJ-6 (Alternative B): *Effects on Environmental Justice Communities of Concern from Construction-related Emissions of Criteria Air Pollutants and Precursors and Exposure of Sensitive Receptors to Substantial Concentrations of Toxic Air Contaminants.* This analysis and conclusion is the same as Impact EJ-4 (Alternative A). Regional and local effects could disproportionately affect minority and low-income populations. Disproportionately high and adverse effects on minority and low-income populations **could occur**.

Impact EJ-7 (Alternative B): *Effects on Environmental Justice Communities of Concern from Physical Impacts on Resources Used for Subsistence Consumption (Fish and Wildlife).* In Reach 2B, the primary resource for subsistence consumption is fishing in Mendota Pool and the river just downstream of Mendota Dam. Alternative B would not make physical changes to the portion of Mendota Pool that is publically accessible and typically used for fishing opportunities. Compared to the No-Action Alternative, the effects of Alternative B would be the same. Therefore, disproportionately high and adverse effects on minority and low-income populations **would not occur** under Alternative B.

Impact EJ-8 (Alternative B): *Effects on Environmental Justice Communities of Concern from Reduced Inadequate or Emergency Access.* Alternative B would have similar effects on environmental justice communities of concern as described for Alternative A; refer to Impact EJ-8 (Alternative A) for more details. Disproportionately high and adverse effects on minority and low-income populations **would not occur**.

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Alternative C proposes habitat restoration activities in conjunction with an expanded floodplain and widened levee alignment, as well as new Project facilities that promote fish passage through Reach 2B. The Project would result in adverse impacts on agricultural resources (refer to Chapter 16, “Land Use Planning and Agricultural Resources”) and generate both socioeconomic impacts associated with losses in agricultural production and benefits attributed to construction and operations spending (refer to Chapter 21, “Socioeconomics and Economics”).

Impact EJ-1 (Alternative C): *Effects on Environmental Justice Communities of Concern from Removal of Land from Agricultural Production*. Alternative C would generally have similar effects on environmental justice communities of concern as described for Alternative A; refer to Impact EJ-1 (Alternative A) for more details.

Compared to No-Action, Alternative C would permanently remove approximately 1,520 acres of agricultural land from production, and additional agricultural land would also be temporarily taken out of production affected during the multi-year construction period. In the context of environmental justice, it is anticipated that approximately 37 farm-level jobs and $1.7 million in annual labor income would be permanently lost under Alternative C, which would be realized predominantly by Hispanic workers characterized by relatively low income levels. Therefore, disproportionately high and adverse effects on minority and low-income populations **could occur** under Alternative C.

Impact EJ-2 (Alternative C): ***Effects on Environmental Justice Communities of Concern from Changes in Regional Activity Attributed to Agricultural Production.*** Alternative C would have similar effects on environmental justice communities of concern as described for Alternative A; refer to Impact EJ-2 (Alternative A) for more details. Compared to No-Action, Alternative C would adversely affect the regional economy based on reductions in agricultural production in the Project area. Agricultural production losses under Alternative C would result in total losses of 67 jobs and $2.7 million annually over the long term throughout Fresno and Madera counties, which are characterized by relatively large numbers of minority and/or low-income populations; therefore, the regional economic impacts anticipated with the Project could adversely affect minority and/or low-income populations residing in the region. As a result, disproportionately high and adverse effects on minority and low-income populations **could occur** under Alternative C.

Impact EJ-3 (Alternative C): ***Effects on Environmental Justice Communities of Concern from Changes in Regional Activity Attributed to Project Construction and Operations.*** Alternative C would have similar effects on environmental justice communities of concern as described for Alternative A; refer to Impact EJ-3 (Alternative A) for more details. Compared to No-Action, Alternative C would generate regional economic benefits based on new spending on construction and operations activities associated with the Project. Within the two-county region, construction activity is expected to support a total of approximately 287 jobs and $18.1 million in labor income annually over the construction period. In addition, operations expenditures would support about $557,000 in labor income annually and 11 jobs over the long term. The regional economic benefits of Project construction and operations anticipated under Alternative C would benefit local residents in Fresno and Madera counties, which are characterized by relatively large numbers of minority and/or low-income populations. As a result, disproportionately high and adverse effects on minority and low-income populations **would not occur** under Alternative C.

Impact EJ-4 (Alternative C): ***Effects on Environmental Justice Communities of Concern from Conversion of Designated Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts.*** This analysis and conclusion is the same as Impact EJ-4 (Alternative A). The conversion of designated Farmland and cancellation of Williamson Act contracts would occur in the Project area and agricultural workers affected by the reduced acreage of farmland are disproportionately racial and/or ethnic minorities relative to State demographics. Disproportionately high and adverse effects on minority and low-income populations **could occur** under Alternative C.

Impact EJ-5 (Alternative C): ***Effects on Environmental Justice Communities of Concern due to Conflicts with Adopted Land Use Plans, Goals, Policies, and Ordinances.*** Alternative C would have similar effects on environmental justice communities of concern as described for Alternative A; refer to Impact EJ-5 (Alternative A) for more details. Disproportionately high and adverse effects on minority and low-income populations **would not occur**.

Impact EJ-6 (Alternative C): ***Effects on Environmental Justice Communities of Concern from Construction-related Emissions of Criteria Air Pollutants and Precursors and Exposure of Sensitive Receptors to Substantial Concentrations of Toxic Air Contaminants.*** This analysis and conclusion is the same as Impact EJ-4 (Alternative A). Regional and local effects could disproportionately affect minority and low-income populations. Disproportionately high and adverse effects on minority and low-income populations **could occur**.

Impact EJ-7 (Alternative C): ***Effects on Environmental Justice Communities of Concern from Physical Impacts on Resources Used for Subsistence Consumption (Fish and Wildlife).*** In Reach 2B, the primary resource for subsistence consumption is fishing in Mendota Pool and the river just downstream of Mendota Dam. Alternative C would change the extent of Mendota Pool, limiting it to Fresno Slough with the Fresno Slough Dam. The area at Mendota Dam would typically have run of the river conditions and fishing regulations used to protect endangered salmon would be enforced in the area. However, subsistence fishing could still continue in Mendota Pool and Fresno Slough, which would remain accessible at nearby Mendota Pool Park. Compared to the No-Action Alternative, the effects of Alternative C would be less than substantial. Therefore, disproportionately high and adverse effects on minority and low-income populations **would not occur** under Alternative C.

Impact EJ-8 (Alternative C): ***Effects on Environmental Justice Communities of Concern from Reduced Inadequate or Emergency Access.*** Alternative C would have similar effects on environmental justice communities of concern as described for Alternative A; refer to Impact EJ-8 (Alternative A) for more details. Disproportionately high and adverse effects on minority and low-income populations **would not occur**.

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Alternative D proposes habitat restoration activities in conjunction with an expanded floodplain and widened levee alignment, as well as new Project facilities that promote fish passage through Reach 2B. The Project would result in adverse impacts on agricultural resources (refer to Chapter 16, "Land Use Planning and Agricultural Resources") and generate both socioeconomic impacts associated with losses in agricultural production and benefits attributed to construction and operations spending (refer to Chapter 21, "Socioeconomics and Economics").

Impact EJ-1 (Alternative D): ***Effects on Environmental Justice Communities of Concern from Removal of Land from Agricultural Production***. Alternative D would generally have similar effects on environmental justice communities of concern as described for Alternative A; refer to Impact EJ-1 (Alternative A) for more details.

Compared to No-Action, Alternative D would permanently remove approximately 1,290 acres of agricultural land from production and 960 acres of cropland would be shifted to livestock grazing. Additional agricultural land would also be temporarily taken out of production affected during the multi-year construction period. In the context of environmental justice, it is anticipated that approximately 56 farm-level jobs and $2.6 million in annual labor income would be permanently lost under Alternative D, which would be realized predominantly by Hispanic workers characterized by relatively low income levels. Therefore, disproportionately high and adverse effects on minority and low-income populations **could occur** under Alternative D.

Impact EJ-2 (Alternative D): ***Effects on Environmental Justice Communities of Concern from Changes in Regional Activity Attributed to Agricultural Production.*** Alternative D would have similar effects on environmental justice communities of concern as described for Alternative A; refer to Impact EJ-2 (Alternative A) for more details. Compared to No-Action, Alternative D would adversely affect the regional economy based on reductions in agricultural production in the Project area. Agricultural production losses under Alternative D would result in total losses of 103 jobs and $4.3 million annually over the long term throughout Fresno and Madera counties, which are characterized by relatively large numbers of minority and/or low-income populations; therefore, the regional economic impacts anticipated with the Project could adversely affect minority and/or low-income populations residing in the region. As a result, disproportionately high and adverse effects on minority and low-income populations **could occur** under Alternative D.

Impact EJ-3 (Alternative D): ***Effects on Environmental Justice Communities of Concern from Changes in Regional Activity Attributed to Project Construction and Operations.*** Alternative D would have similar effects on environmental justice communities of concern as described for Alternative A; refer to Impact EJ-3 (Alternative A) for more details. Compared to No-Action, Alternative D would generate regional economic benefits based on new spending on construction and operations activities associated with the Project. Within the two-county region, construction activity is expected to support a total of approximately 258 jobs and $15.8 million in labor income annually over the construction period. In addition, operations expenditures would support about $564,000 in labor income annually and 11 jobs over the long term. The regional economic benefits of Project construction and operations anticipated under Alternative D would benefit local residents in Fresno and Madera counties, which are characterized by relatively large numbers of minority and/or low-income populations. As a result, disproportionately high and adverse effects on minority and low-income populations **would not occur** under Alternative D.

Impact EJ-4 (Alternative D): ***Effects on Environmental Justice Communities of Concern from Conversion of Designated Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts.*** This analysis and conclusion is the same as Impact EJ-4 (Alternative A). The conversion of designated Farmland and cancellation of Williamson Act contracts would occur in the Project area and agricultural workers affected by the reduced acreage of farmland are disproportionately racial and/or ethnic

minorities relative to State demographics. Disproportionately high and adverse effects on minority and low-income populations **could occur** under Alternative D.

Impact EJ-5 (Alternative D): *Effects on Environmental Justice Communities of Concern due to Conflicts with Adopted Land Use Plans, Goals, Policies, and Ordinances.* Alternative D would have similar effects on environmental justice communities of concern as described for Alternative A; refer to Impact EJ-5 (Alternative A) for more details. Disproportionately high and adverse effects on minority and low-income populations **would not occur**.

Impact EJ-6 (Alternative D): *Effects on Environmental Justice Communities of Concern from Construction-related Emissions of Criteria Air Pollutants and Precursors and Exposure of Sensitive Receptors to Substantial Concentrations of Toxic Air Contaminants.* This analysis and conclusion is the same as Impact EJ-4 (Alternative A). Regional and local effects could disproportionately affect minority and low-income populations. Disproportionately high and adverse effects on minority and low-income populations **could occur**.

Impact EJ-7 (Alternative D): *Effects on Environmental Justice Communities of Concern from Physical Impacts on Resources Used for Subsistence Consumption (Fish and Wildlife).* In Reach 2B, the primary resource for subsistence consumption is fishing in Mendota Pool and the river just downstream of Mendota Dam. Alternative D would change the extent of Mendota Pool, limiting it to Fresno Slough with the Fresno Slough Dam. The area at Mendota Dam would typically have run of the river conditions and fishing regulations used to protect endangered salmon would be enforced in the area. However, subsistence fishing could still continue in Mendota Pool and Fresno Slough, which would remain accessible at nearby Mendota Pool Park. Compared to the No-Action Alternative, the effects of Alternative D would be less than substantial. Therefore, disproportionately high and adverse effects on minority and low-income populations **would not occur** under Alternative D.

Impact EJ-8 (Alternative D): *Effects on Environmental Justice Communities of Concern from Reduced Inadequate or Emergency Access.* Alternative D would have similar effects on environmental justice communities of concern as described for Alternative A; refer to Impact EJ-8 (Alternative A) for more details. Disproportionately high and adverse effects on minority and low-income populations **would not occur**.

11.0 Geology and Soils

This chapter describes the environmental and regulatory settings for geology and soils, including mineral resources (sand, gravel, rock, gold, oil, and natural gas), erosion, sedimentation, and geomorphic processes. The chapter includes a discussion of existing geology and soils conditions and the potential impacts of the Project alternatives on geology and soils along the San Joaquin River from the Chowchilla Bifurcation Structure to approximately 2 miles below Mendota Dam. The Project area comprises the area that could be directly or indirectly affected by the Project. The Project area is located in Fresno and Madera counties, near the town of Mendota, California.

11.1 Environmental Setting

Because of the regional-scale nature of earth resources, the geology and soils characteristics addressed in this section are described in a regional context, referring to geologic and geomorphic provinces, physiographic regions, or other large-scale areas, as appropriate.

11.1.1 Geology

The various geologic processes active in California over millions of years have created many geologically and geomorphically different areas, called geomorphic provinces. The upper San Joaquin River lies in the Sierra Nevada Province and lower San Joaquin River and the Project area are in the Central Valley Province (California Geological Survey [CGS] 2002a).

The upper San Joaquin River is located in the central portion of the Sierra Nevada Province at its boundary with the eastern edge of the Central Valley Province. The Sierra Nevada Province encompasses the Sierra Nevada Mountains, and comprises primarily intrusive rocks, including granite and granodiorite,[1] with some metamorphic rocks that formed due to contact at depth with the intruding igneous rocks. Extrusive rocks also occur. Evidence of previous episodic volcanic activity within the San Joaquin River watershed includes discontinuous Pliocene to Pleistocene deposits observed within the middle fork of San Joaquin River, the Miocene deposits within the vicinity of Millerton Lake, and the Pleistocene Friant Pumice found downstream of Friant Dam (Wakabayashi and Sawyer 2001, Huber 1981, McBain & Trush 2002).

The Sierra Nevada Province is a tilted fault block nearly 400 miles long, with a high, steep multiple-scarp east face and a gently sloping west face that dips beneath the Central Valley Province (CGS 2002a). The central Sierra Nevada has a complex history of uplift and erosion. The greatest uplift tilted the entire Sierra Nevada block to the west. The high

[1] Granodiorite is an igneous rock similar to granite, but contains more plagioclase (calcium and sodium) feldspar than potassium feldspar and has more dark minerals.

elevation of the Sierra Nevada Mountains leads to the accumulation of snow, including the Pleistocene glaciation responsible for shaping much of the range. Snowmelt in the Sierra Nevada feeds the San Joaquin River and its major tributaries, including those upstream from Friant Dam as well as the Merced, Tuolumne, Stanislaus, and Mokelumne rivers and other tributaries downstream from the Merced River confluence. These large rivers and their smaller tributaries cut through the granitic rocks present in the upper San Joaquin River watershed, and through intrusive and extrusive rock formations and sedimentary and metamorphosed rocks farther to the west. The metamorphic bedrock in these watersheds contains gold-bearing veins in the northwest-trending Mother Lode that are not present in the more southerly watershed of the upper San Joaquin River (CGS 2002b).

The Central Valley Province encompasses the Central Valley, an alluvial plain about 50 miles wide and 400 miles long in the central part of California, stretching from just south of Bakersfield northward to Redding. The San Joaquin Valley makes up approximately the southern half of the Central Valley Province and is drained by the San Joaquin River. The Sacramento Valley makes up the northern half of the Central Valley Province and is drained by the Sacramento River. The San Joaquin River and its tributaries flow out of the Sierra Nevada Province into the Central Valley, depositing sediments on alluvial fans, in riverbeds, on floodplains, and on wetlands of the Central Valley Province. The Central Valley Province is characterized by alluvial deposits and continental and marine sediments deposited almost continually since the Jurassic Period (CGS 2002b). Quaternary age[2] alluvium is identified and mapped at the ground surface throughout the entire Project area and vicinity (Figure 11-1).

Alternating marine and continental deposits of Tertiary age underlie much of the Central Valley Province, including the San Joaquin Valley (Page 1986). The more recent Quaternary Period was characterized by continental sedimentary deposition. Tertiary and Quaternary continental formations in the San Joaquin Valley are composed of alluvial deposits of gravel, sand, silt, and clay and contain lenses of clay and silt comprising lacustrine, marsh, and floodplain deposits. These Tertiary and Quaternary deposits are of varying thickness, in some instances, thousands of feet thick (Page 1986). Continental formations (i.e., Mehrten, Kern River, Laguna, San Joaquin, Tulare, Tehama, Turlock, Riverbank, and Modesto Formations) make up the major aquifer(s) of the San Joaquin Valley (Ferriz 2001, Page 1986).

[2] The Quaternary Period, our current period in the geologic time scale, is divided into two epochs: the Pleistocene (2.588 million years ago to 11.7 thousand years ago) and the Holocene (11.7 thousand years ago to today).

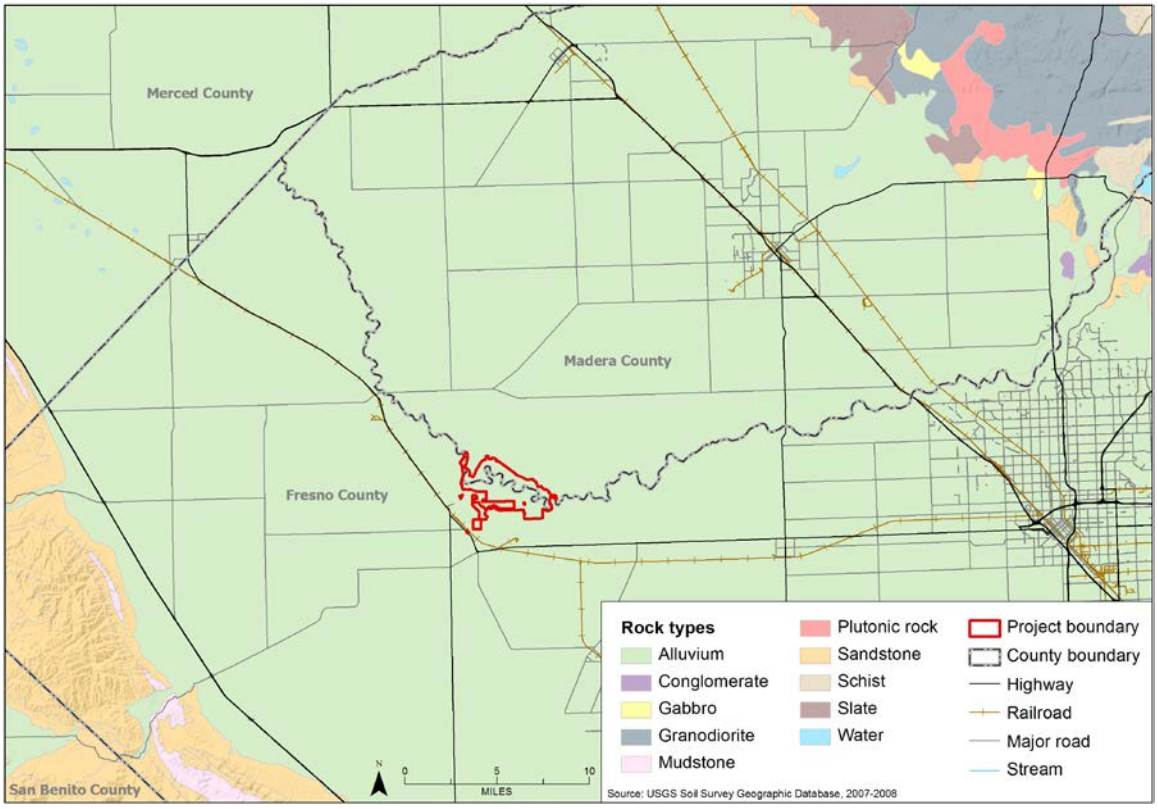

Figure 11-1.
Regional Geology

The San Joaquin Valley is a structural trough into which sediments have been deposited as much as 6 miles deep. Some of these sediments eroded from the Sierra Nevada and were transported and deposited in the Central Valley. Tectonic activity during the Tertiary Period strongly influenced the evolution of the Central Valley, alternately trapping water in the San Joaquin Valley or entire Central Valley to form inland seas that deposited marine sediments, and opening to allow drainage to the ocean, as under current conditions.

Surficial geology along Reach 2B is dominated by Holocene age alluvial deposits. These geologically young deposits cover the entire central San Joaquin Valley area. No bedrock is present on the ground surface. Sedimentary rock is exposed to the west in the Coast Ranges and igneous and metamorphic rocks are present in the Sierra Nevada to the east.

11.1.2 Soils

Soil development depends on parent material, climate, associated plants, topography, and age. Because these factors are similar within physiographic regions, soils within a physiographic region are often similar.

Soil Type

Soils in the Project area are described as valley basin soils on the regional soil map (University of California Division of Agricultural Sciences 1980) (Figure 11-2). Valley Basin soils consist of organic soils, imperfectly drained soils, and saline and alkali soils in the valley trough and on the basin rims.

The Valley Basin imperfectly drained soils generally contain dark clays, have a high water table, and are subject to overflow. These soils are found in the trough of the San Joaquin Valley, and consist in part of several thick lake bed deposits.

The Valley Basin saline/alkali soils are characterized by excess salts (saline), excess sodium (sodic), or both (saline-sodic). In many of the older soil surveys, salinity and sodicity were jointly referred to as alkaline. A distinction was sometimes made because the saline soil many times formed a white crust on the surface and was called "white alkali," and the soils with excess sodium appeared to be "black," thus, black alkali. Both are fairly common throughout the San Joaquin Valley. In uncultivated areas, saline soils are used for saltgrass pasture and native range. Some of these soils support seasonal salt marshes. In areas of intermediate to low rainfall, these soils are saline-sodic. Many of these soils are irrigated with moderately saline Delta surface water, imported via the Delta-Mendota Canal (DMC), or with slightly saline groundwater. In addition, salts are added through application of fertilizers or other additives needed for cropping.

The accumulation of salts in the soils of the San Joaquin Valley is due to a combination of the regional geology, high water table, intensive irrigation practices, and the importation of water from the Delta that is moderate in salinity and application to lands in the region. The Corcoran Clay and other clay layers contribute to a naturally high water table in the valley, concentrating salts in the root zone by evaporation through the soil. Farmers actively leach these salts from the soil into drainage water with irrigation and subsurface drainage practices. Drainage water with high concentrations of salts may be reused for irrigation (with or without treatment), accumulate in groundwater, or be discharged to evaporation ponds or tributaries to the San Joaquin River. Salinization caused by concentrations of naturally-occurring soil salts is exacerbated by the use of more saline Delta water, imported via the DMC and California Aqueduct, as a major source of irrigation water.

Additionally, naturally occurring trace elements in soils may be mobilized and concentrated along with salts. Soils throughout the San Joaquin Valley typically contain some selenium, and soils on the west side of the valley are particularly selenium-rich. These soils have developed on alluvial deposits comprising eroded material from the Coast Range, where selenium is found in marine deposits. Selenium can pose a hazard to fish and wildlife when it becomes highly concentrated in surface waters.

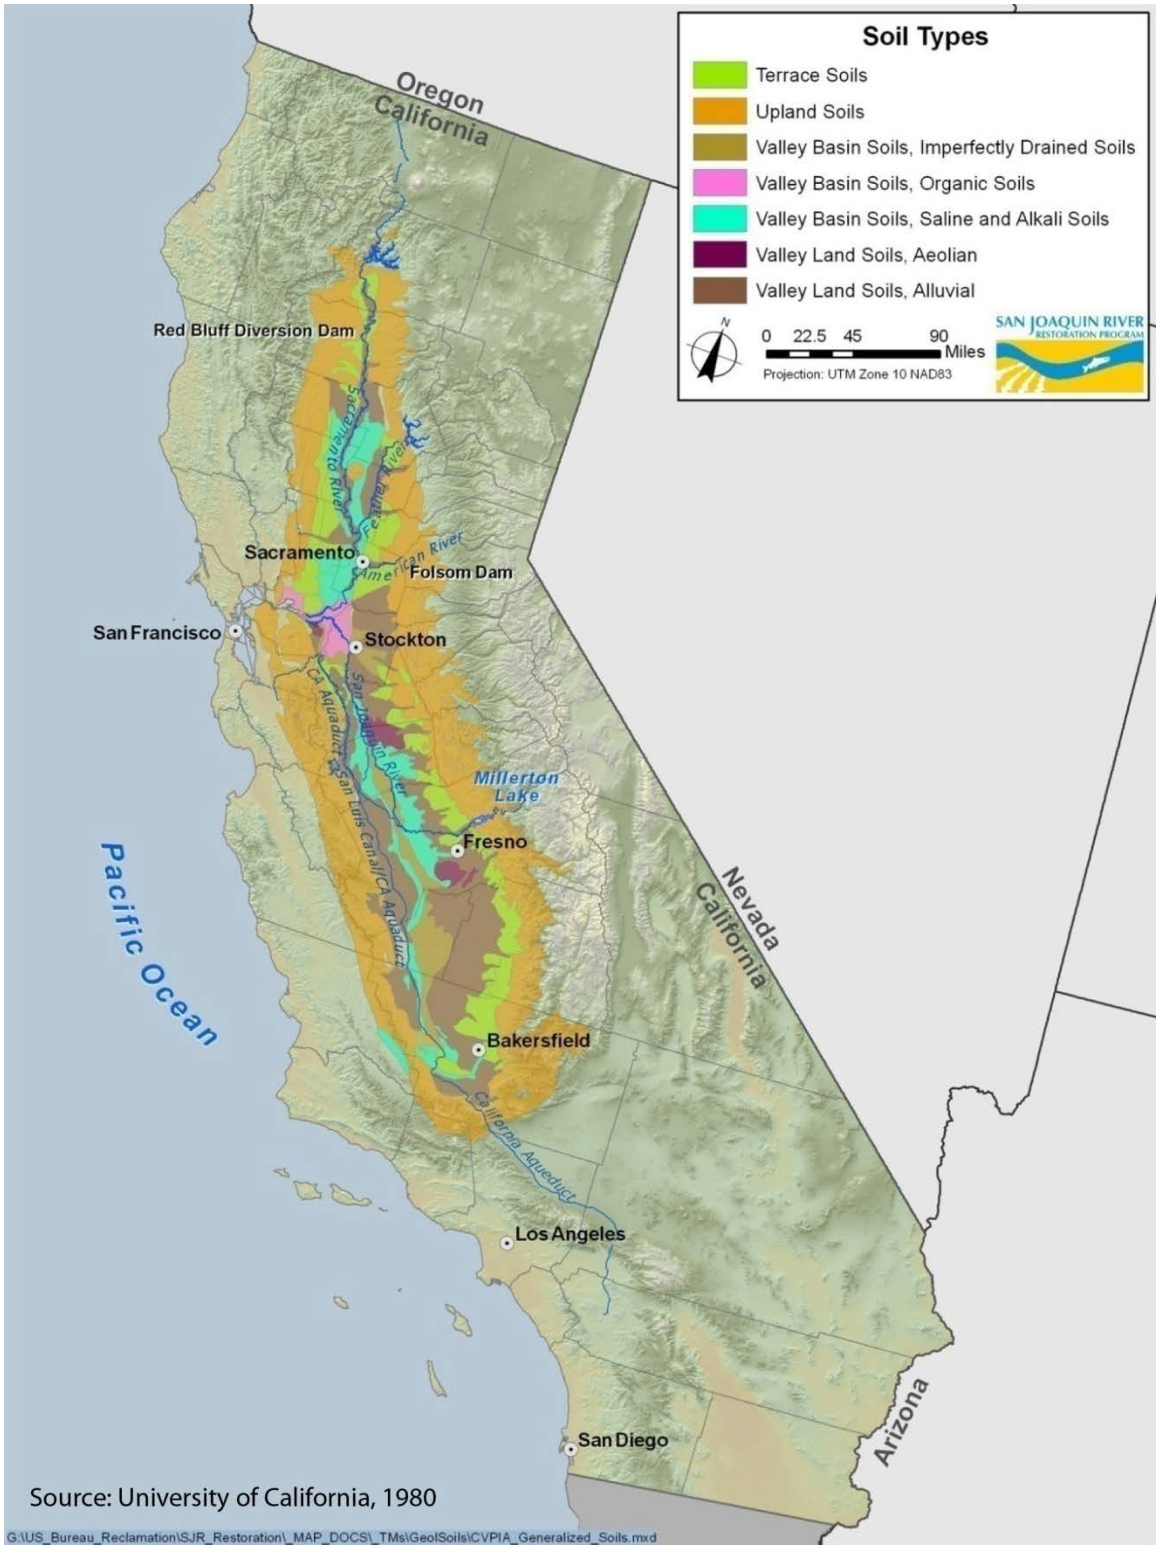

Figure 11-2.
Physiographic Soil Types in the Central Valley and Delta

A soil map of the Project footprint is shown on Figure 11-3 and the acreage of each soil type is presented in Table 11-1. The main soil types mapped in the area are Grangeville fine sandy loam, Chino fine sandy loam, and Chino loam (National Resources Conservation Service [NRCS] 2008). All of these soils are mixtures of sand, silt, and clay derived primarily from the weathering of granitic bedrock; the soils are differentiated based upon several soil properties such as amount of calcium carbonate or salt or organic matter content, for example. The primary use of soils within the Project area is for farming.

Table 11-1.
General Soils Data in the Project Footprint

Soil Type	Acreage
Cajon loamy sand	0.5
Calflax clay loam	3.0
Chino fine sandy loam	325
Chino loam	1,812

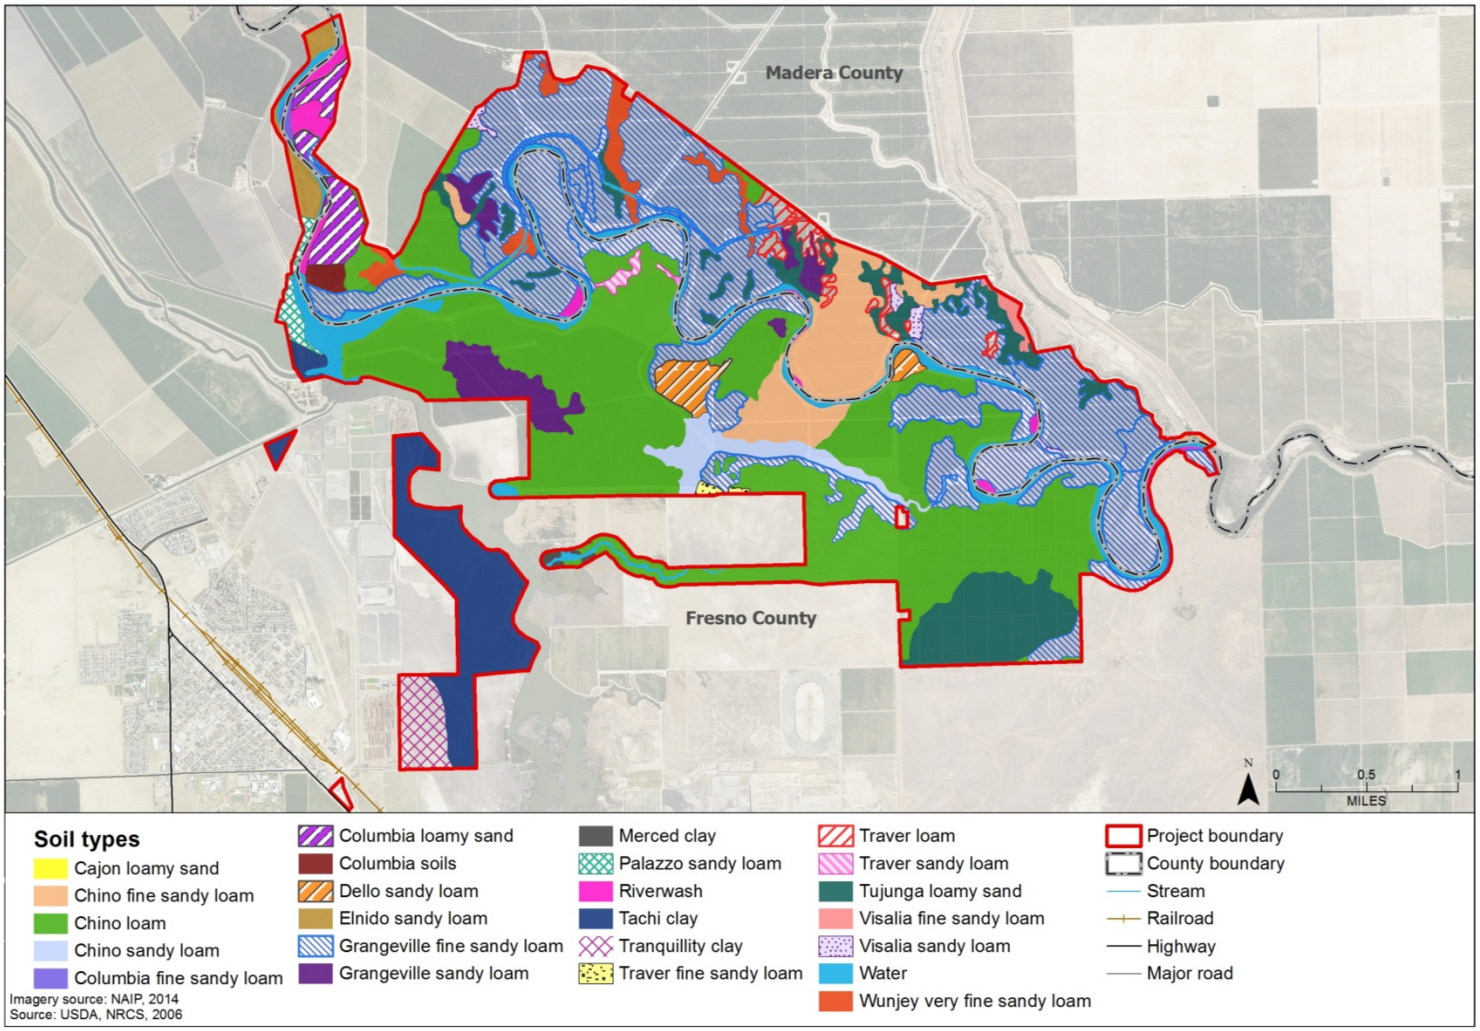

Figure 11-3.
General Soils Type in the Project Footprint

Generalized Soil Texture

Soils and sediments in the Project area and vicinity are composed of a heterogeneous mix of recent river channel deposits, recent floodplain deposits, and older deposits. The texture of these sediments ranges from coarse-grained gravels to fine-grained clays, and the distribution of these textures can have a strong influence on the hydrogeology of the underlying aquifer system. Table 11-2 contains the calculated areas in acres for each generalized soil texture in the Project area. Soils are predominantly classified as sandy loam and loam.

Table 11-2.
Acreages of Soil Textures in Project Footprint

Soil Texture	Acreage
Clay/Clay Loam	453
Loam	1,875
Sand	489
Sandy Loam	2,547
Variable[1]	530
Total Acreage	5,894

Source: NRCS 2008

Note:

[1] The category "variable" includes soils of undifferentiated texture and areas that were not mapped by the National Resources Conservation Service (i.e., areas covered by water during the mapping period).

Levee seepage has been a concern in the Project area and vicinity. Under-seepage, water that seeps laterally by travelling under a dam or levee section, can occur when structures are underlain by permeable native soils. Movement of water through or underneath levees, commonly appearing as boils or piping (seeps), may saturate the levee or transport foundation materials and compromise the short- or long-term integrity of the levee. Levee seepage can also raise groundwater surface elevations in adjacent areas, thereby increasing soil saturation and potentially reducing crop yields and/or increasing crop mortality.

11.1.3 Erosion and Sedimentation

The sediment load of the San Joaquin River and its tributaries originates from the erosion of soil and rock in the watershed. The sediment load of the San Joaquin River, like most rivers, generally becomes finer grained with distance downstream.

Soil Erosion Potential

Soil erosion is a natural physical process of wearing away and transport of soil materials by wind, water, ice, and gravity. Erosion can remove soils, undermining structures like bridges, and can lead to unstable steep slopes. Erosion is followed by deposition of the eroded materials, typically in low-lying areas, causing sedimentation of streams and reservoirs. Erosion also can result in landslides that may damage roads, buildings, and other infrastructure. Soil characteristics that affect the erosion rate are soil surface texture and structure, particle size, permeability, infiltration rate, and the presence of organic or other cementing materials. Other key factors determining erosion potential are the extent

of vegetation, type of cover (vegetative or otherwise), human or other disturbance, topography, and rainfall.

Human activities can also effectively accelerate natural erosion processes. Localized sedimentation problems can occur with construction and development or agricultural activities, which usually involve vegetation removal, compaction of porous soils, and concentrated drainage from large areas. Improper agricultural management practices can accelerate erosion. Overgrazing and land clearing, particularly on steep slopes, but also on flat areas, make surfaces vulnerable to topsoil loss. Elevation measurements made from 1922 to 1981 indicate that even typical agricultural practices, regardless of crop type, may cause up to 1 to 3 inches of soil loss per year (Rojstaczer et al. 1991).

Infrastructure Effects on Sediment Transport

A significant effect of dams and water storage reservoirs on a watershed is on sediment supply because they serve as impediments to downstream sediment transport. Because of the slowing of stream flow velocity in the reservoir, sediment settles out of the water column and onto the reservoir bottom. Although the water and some of its fine sediment may be released on the downstream side of the dam, the majority of the sediment load, particularly the coarser materials (gravel, sand, and some silt), remains on the upstream side. Friant Dam stops most of the sediment from the upper San Joaquin River watershed from moving downstream. Reservoirs also create a transport-limited system downstream of the dam by reducing the frequency and/or intensity of natural high-flow regimes that were prevalent prior to dam construction. This limits gravel mobility and promotes bed coarsening/bed armoring.

Under unaltered conditions, fluvial processes, including sediment transport, are naturally adjusted along the length of a river to match the channel gradient, stream discharge, and sediment load. Flow energy in the river channel is dissipated gradually. Bridges and culverts constrict the natural channel and disrupt these processes. This may occur at high and/or low flows, depending on the size of the structure.

Effects of channel constrictions caused by bridge and culvert crossings include the following:

- Sediment deposition upstream from the constriction (backwater effects).
- Scour at the constriction due to an elevated water surface and increased water velocity.
- Sediment deposition downstream from the constriction due to flow expansion, leading to the formation of splay bars.
- Reduced flood conveyance capacity due to filling in of floodplain space when building bridge and culvert abutments.
- Catastrophic erosion of bridge or culvert crossing (and possibly surrounding areas) during large storm events due to channel blockage at constriction by debris such as trees, bushes, or other natural or man-made materials.

The function and operation of the water supply and flood control infrastructure present in the Project area and vicinity also affect fluvial processes of the San Joaquin River. Such infrastructure includes diversion structures, bypasses and bypass diversions, other hydraulic control structures, off-stream flood control dams, levees, and canals. These structures divert base flows and/or flood flows and constrict flood flows and thereby significantly alter fluvial processes. The processes most affected are sediment transport, local incision and deposition, and channel migration (Table 11-3).

Table 11-3.
Generalized Effects on Geomorphic Processes of Major Flood Control and Water Supply Infrastructure

Infrastructure	Effects
Diversion structures	Backwater effects cause disruption of local incision and deposition patterns; riprap protection prevents channel migration and avulsion; reroute sediment load
Bypasses	Reroute sediment load within the Project area
Bypass diversion structures	Backwater effects cause disruption of local incision and deposition patterns; reroute sediment load within the Project area
Other hydraulic control structures	Backwater effects cause disruption of local incision and deposition patterns; reroute sediment load within the Project area
Offstream flood control dams	Reroute sediment load within the Project area and vicinity
Levees	Dissect the historic floodplain, stop channel migration and avulsion, increase river velocity and, thus, also increase incision, bed armoring, and channel simplification
Canals	Embankments dissect the historic floodplain, stop channel migration and avulsion, increase river velocity and, thus, also increase incision, bed armoring, and channel simplification; reroute sediment load

Sediment load is carried by stream flow, and infrastructure that reroutes these flows alters sediment transport. Levees and canal embankments, especially those that are constructed within the floodplain and not sufficiently set back from the channel, dissect the historic floodplain preventing channel migration and avulsion.[3] This prevents oxbow formation and also increases river velocity, which encourages channel incision, bed armoring, and channel simplification.

Specific flood control and water supply infrastructure in the Project area and its effects on sediment transport are discussed below.

Local Erosion and Sedimentation

With the combination of agricultural development, reduction of the high-flow regime under controlled releases from Friant Dam, construction of levees, and incorporation of flood control structures with bypass channels, such as the Chowchilla Bypass, the river channel became simplified. High-flow scour channels were eliminated, the main channel footprint was reduced, and side channels were cut off from the main river. Prior to

[3] Avulsion is the rapid abandonment of a river channel and the formation of a new river channel.

implementation of Interim Flows, most sediment was routed through the Chowchilla Bypass and very little sediment moved through Reach 2B. Instead, most sediment was routed with flows into the bypass, or accumulated in sand traps immediately upstream of the bypass.

Historically, when flows through Reach 2 were more consistent, sediment supply and transport capacity decreased gradually from Reach 1B through Reach 2 as sediment was deposited on the floodplain and multiple side channels evolved across the floodplain. This is demonstrated by the presence of remnant channel deposits and relic floodplain features.[4] As water infrastructure was built in Reach 2B, sediment transport was affected. Small diversion structures, like Mendota Dam, affect sediment transport by modifying the delivery of sediment downstream. The culvert at the San Mateo Avenue crossing is a constriction in the stream channel during low stream flows, which can cause backwater, scour, and deposition. At higher discharge levels, the culvert becomes overwhelmed and the river flows over the crossing.

Lack of vegetation and the sandy substrate would cause the riverbed to be easily eroded when flows pass through the reach. Bed mobility can occur at most baseflows, and bed scour could occur throughout the reach at moderate to high flows. As a result of this erosion, channel avulsion and migration could occur between the levees if the levees were not constraining the channel. The river banks are another area where soil erosion is occurring in the Project footprint and are likely areas where soil erosion would occur in the future. U.S. Geological Survey (USGS) data (USGS 2007 and 2008) indicate that soils, primarily on the left bank, may be highly erodible (Figure 11-4).

11.1.4 Geomorphology

The San Joaquin Valley floor is divided into several geomorphic land types, including dissected uplands, alluvial fans and plains, river channels and floodplains, and overflow lands and lake bottoms. The alluvial plains cover most of the valley floor and make up some of the intensely developed agricultural lands in the San Joaquin Valley. River floodplains and channels lie along the major rivers and to a lesser extent the smaller streams that drain into the valley from the Sierra Nevada. Some floodplains are well-defined where rivers incise their alluvial fans. These deposits tend to be coarse and sandy in the channels and finer and silty in the floodplains. Lake bottoms of overflow lands include historical beds of Tulare Lake, Buena Vista Lake, and Kern Lake as well as other less defined areas in the valley trough.

The Project footprint extends downstream from the Chowchilla Bifurcation Structure to about 2 miles below Mendota Dam. The lack of confining features and the reduced gradient in Reach 2B both cause the channel to change to sand-bedded, meandering morphology. Meanders become more sinuous in Reach 2B than upstream as the river runs up against the alluvial deposits of the Coast Range drainages. This is also the point of diversion for the Chowchilla Bifurcation Structure, which, prior to Interim Flows, diverted most of the flows that enter Reach 2B into the Chowchilla Bypass. Lone Willow

[4] Relic floodplain features, which have coarser sediment than the adjacent floodplain, may provide a lateral conduit for levee seepage.

Slough is a historical side channel that begins near the Chowchilla Bifurcation Structure and terminates in Reach 3. Today, this channel carries riparian diversions for irrigation, agricultural return flows, and runoff.

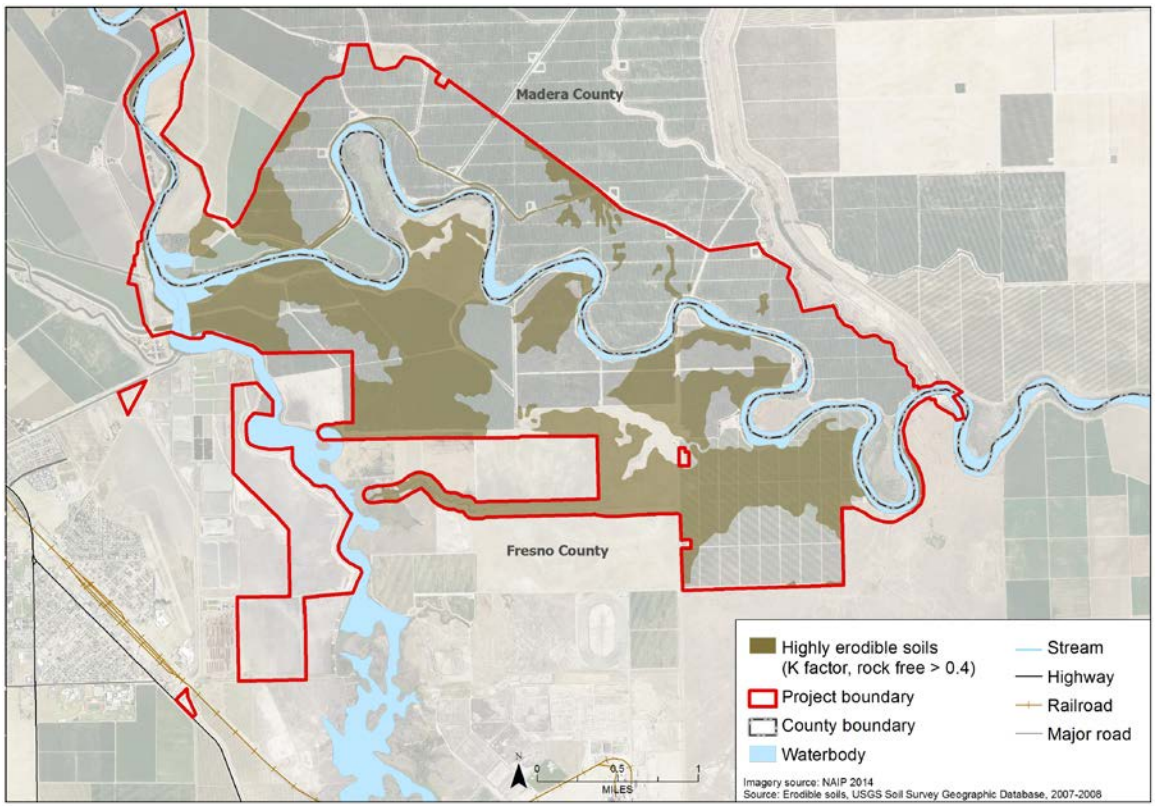

Figure 11-4.
Erodible Soils in the Project Footprint

The river slope in Reach 2B decreases to 0.00022 or about 1 foot per mile, which is almost a factor of 2 less than the slope in Reach 2A. The median bed material diameter is approximately 0.026 inches (Mussetter Engineering, Inc. 2002). Currently, water operations allow a maximum flow of approximately 810 cubic feet per second (cfs) in this reach with all excess flow diverted into the Chowchilla Bypass. The geomorphology of Reach 2B is discussed in depth in Chapter 14.0, "Hydrology – Surface Water Resources and Water Quality."

11.1.5 Soil Hazards

Reach 2 soils have natural selenium content. According to a soil survey from the mid-1980s, soils in the upper portion of the Project footprint contain 0.10 to 0.13 parts per million (ppm) of selenium in the top 12 inches of soil. The lower portion of the Project footprint contains 0.14 to 0.36 ppm selenium in the top 12 inches of soil (San Joaquin Valley Drainage Implementation Program [SJVDP] 1990). Data collected more recently from Mendota Pool found selenium concentrations in sediments up to 0.95 ppm, but aqueous concentrations in soil elutriate were less than 3 parts per billion (ppb) which is

below the aquatic life criteria of 5 ppb (San Joaquin River Restoration Program [SJRRP] 2012). The presence of selenium can affect surface water quality and is discussed in Chapter 14, "Hydrology – Surface Water Resources and Water Quality."

Soil corrosivity involves the measure of the potential of corrosion for steel and concrete caused by contact with some types of soil. Knowledge of potential soil corrosivity is often critical for the effective design of cathodic protection of buried steel and concrete elements. Factors including soil composition, soil chemistry, moisture content, and pH affect the response of steel and concrete to soil corrosion. Soils with high moisture content, high electrical conductivity, high acidity, or high dissolved salts content are most corrosive. In general, sandy soils have high resistivities and are the least corrosive. Clay soils, including those that contain interstitial salt water, can be highly corrosive.

Figure 11-5 indicates that the soils in the Project footprint generally have low corrosivity to buried concrete elements except in the Fresno Slough area were soils are moderately corrosive to concrete. Figure 11-6 shows that the soils generally have high corrosivity to buried steel.

Expansive soils are those that undergo a significant increase in volume during wetting, and shrink in volume as they decrease in water content, also known as shrink-swell soils. Expansive soils can cause significant damage to structures due to increases in uplift pressures. Soils are generally classified as having low, moderate, and high expansive potentials. Soils containing a high percentage of clay types particularly susceptible to expansion usually have high expansive potentials, and more granular sands and gravels generally have low expansive potential. Figure 11-7 shows that nearly all of the soils within the Project footprint have low shrink-swell potential. The southwest portion of the site west of Fresno Slough has very high shrink-swell potential.

11.1.6 Mineral Resources

In 2006, California ranked third in the nation in nonfuel mineral production. In that year, California yielded $4.6 billion in nonfuel minerals, totaling 7 percent of the Nation's entire production (Kohler 2006). Of these products, construction sand and gravel are the most widely mined resources in the vicinity of the San Joaquin River. Historically, gold was also extracted from the riverbed.

Sand, Gravel, and Other Rock Products

In 2006, California was the Nation's largest producer of construction sand and gravel ($1.5 billion) and Portland cement ($1.25 billion) (Kohler 2006). California also produced significant quantities of crushed stone ($481 million), industrial sand and gravel ($62.2 million), masonry cement ($87.8 million), and dimension stone ($11.2 million). Together, the market value of these products total $3.4 billion, almost 75 percent of the total value of State nonfuel mineral production. The San Joaquin River below Friant Dam is a significant source of sand and gravel in the State, and mining occurs at multiple locations on the floodplain and river terraces upstream of the Project area (Mussetter Engineering, Inc. 2002). One aggregate mine is present near the downstream limit of the Project footprint (Figure 11-8) (California Department of Conservation, Office of Mine Reclamation 2011).

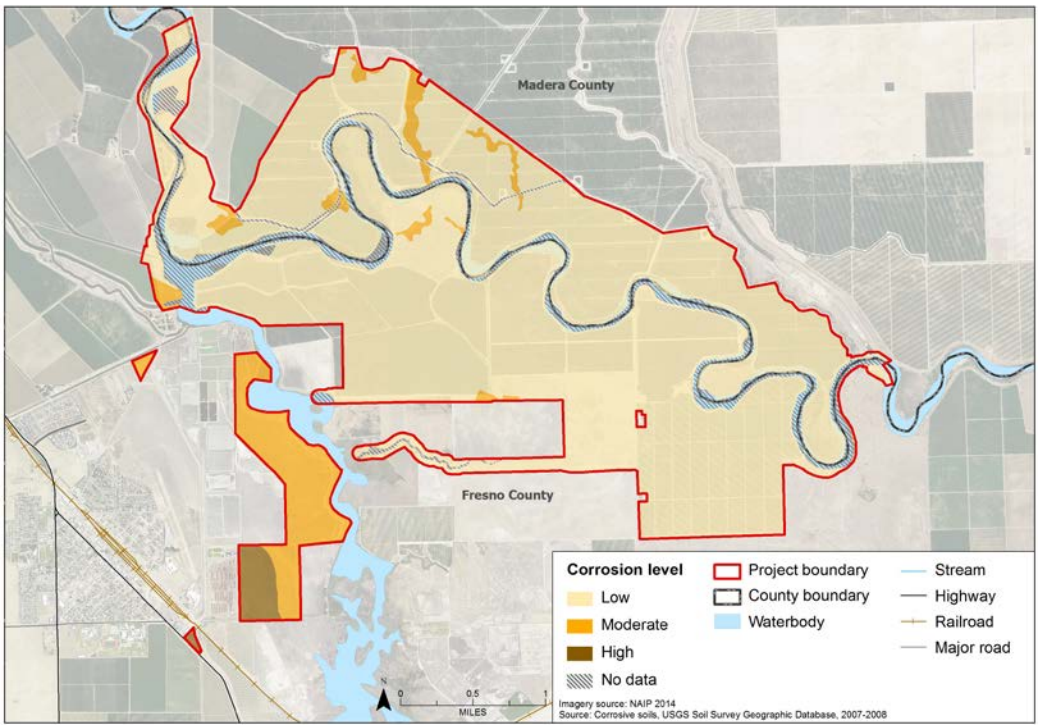

Figure 11-5.
Corrosion Level of Soils to Concrete in the Project Footprint

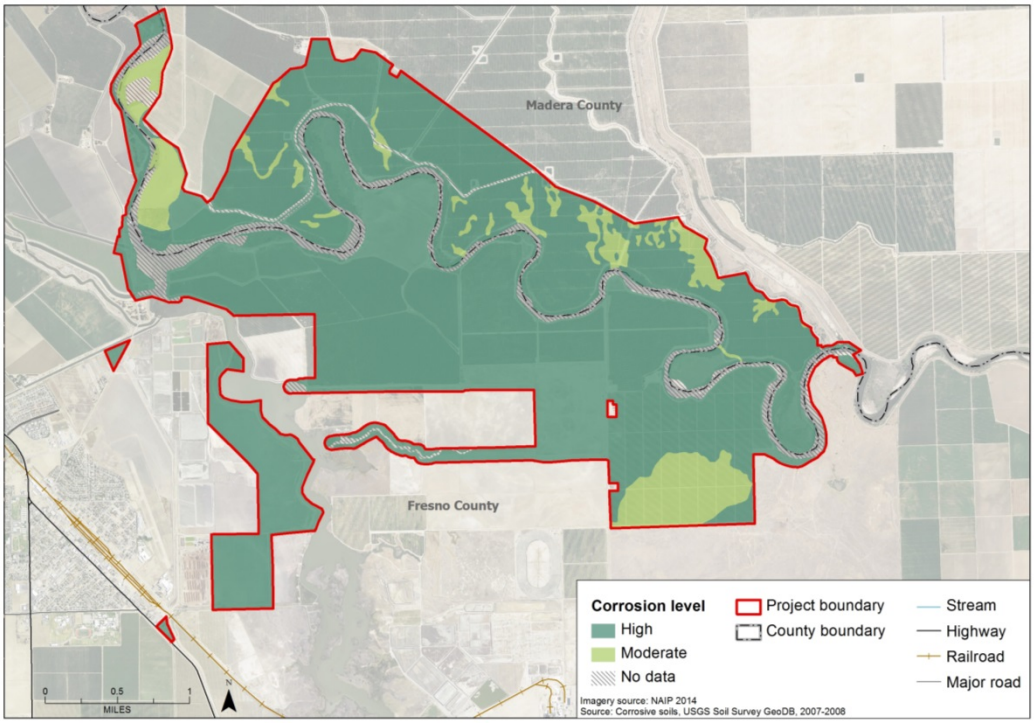

Figure 11-6.
Corrosion Level of Soils to Uncoated Steel in the Project Footprint

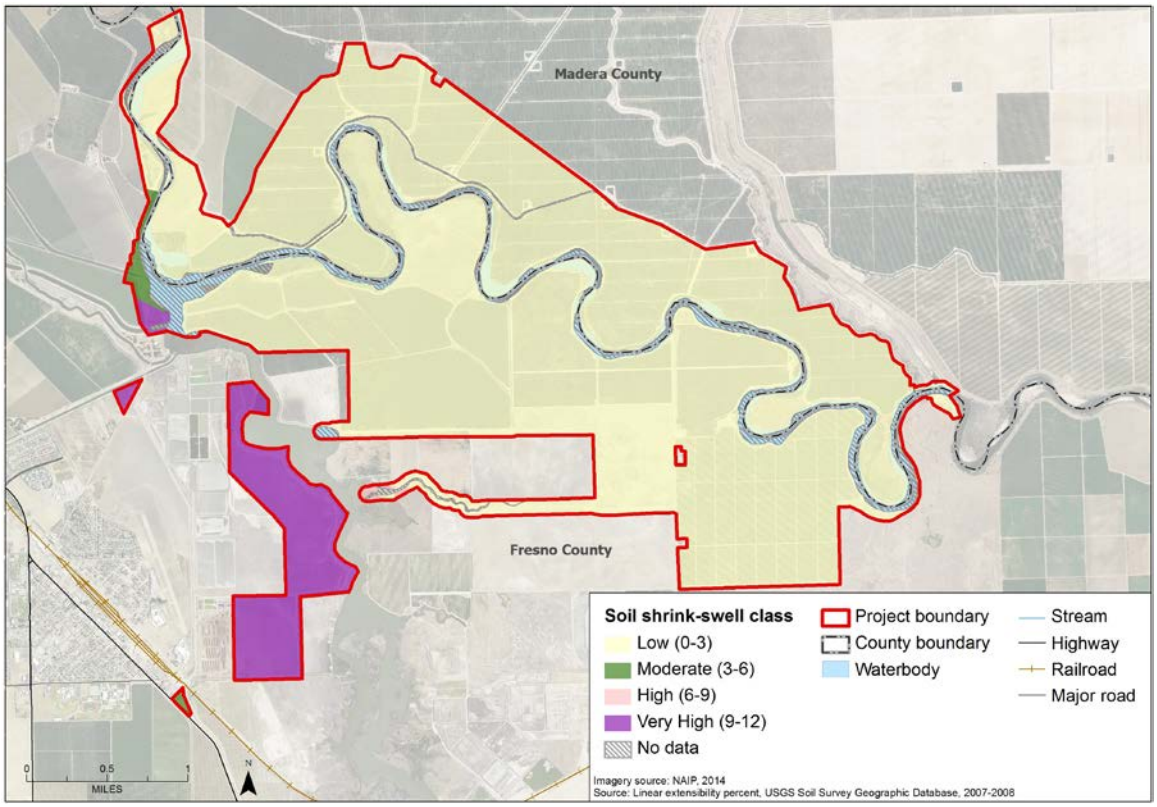

Figure 11-7.
Soil Shrink-Swell Classes in the Project Footprint

Gold

Gold has been mined from placer deposits in loosely consolidated alluvial sediments throughout the Sierra Nevada foothills. The San Joaquin River above Friant Dam was subject to some degree of placer mining from 1848 to 1880, followed by dredge mining from 1880 to the 1960s (Mussetter Engineering, Inc. 2002). These activities significantly reworked the riverine environments, redistributing sediments and altering channel forms. However, the San Joaquin River was less affected by dredge mining than the more northerly Sierra Nevada drainages, where gold was more plentiful (McBain and Trush 2002). Aside from recreational gold mining that has been observed to occur near the town of Friant, gold extraction does not currently occur on any part of the San Joaquin River.

Oil and Natural Gas

The San Joaquin Valley is one of the largest sources of oil in California, although most of the oil wells are south of the Project area. Figure 11-9 shows nearby oil fields. None are within the Project footprint.

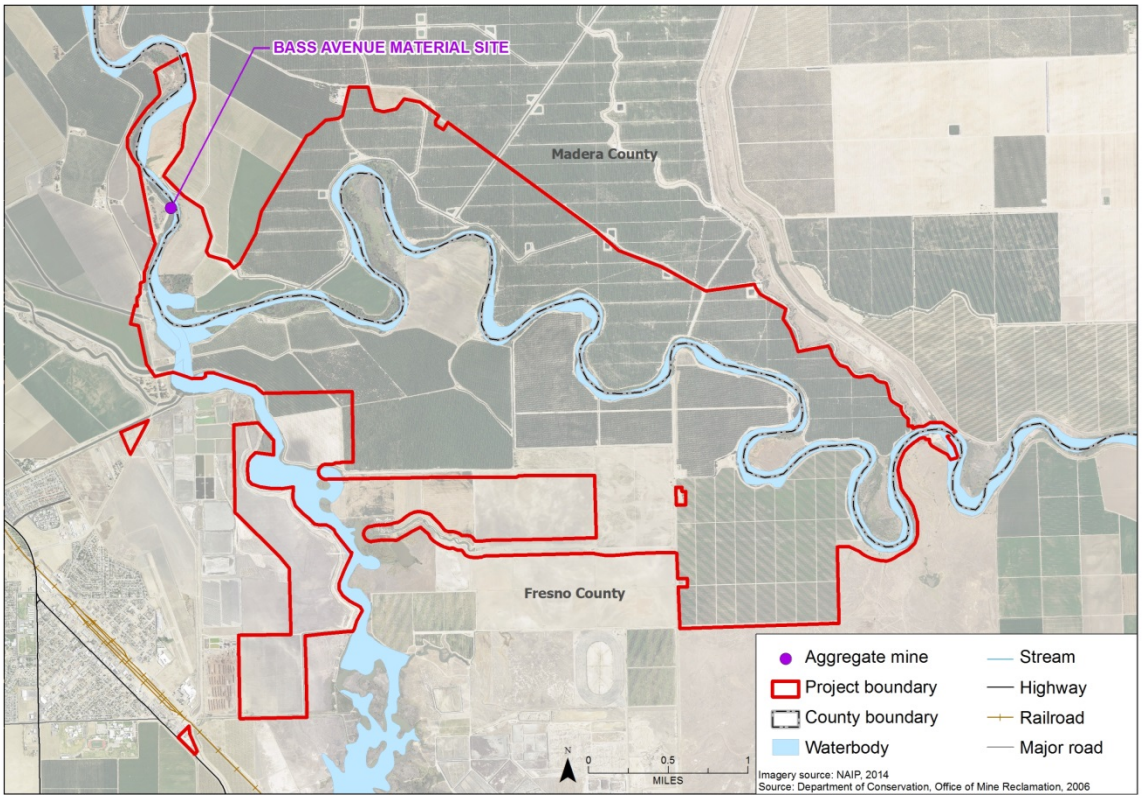

Figure 11-8.
Aggregate Mines in the Project Footprint

Local Mining

Local landowners perform some sand mining near the river channel, leaving pits 10 to 15 feet deep. The pits appear to fill after a single flood control release from Friant Dam. As stated above, one aggregate mine is present in the Project footprint near the downstream end below Mendota Pool (Figure 11-8). No gold is mined in the Project area.

11.1.7 Seismicity and Neotectonics

Both the Sierra and Central Valley geologic provinces continue to be subject to minor tectonic activity. Locally, normal faults are found in the Sierra Nevada foothills, probably because the west, or valley, side of the Sierra block is subsiding faster than uplift of the east side (Bartow 1991). The closest faults of the Foothills Fault System are located about 40 miles north of the Project area and the closest fault strands with activity within the last 700,000 years are more than 70 miles to the north (Jennings and Bryant 2010).

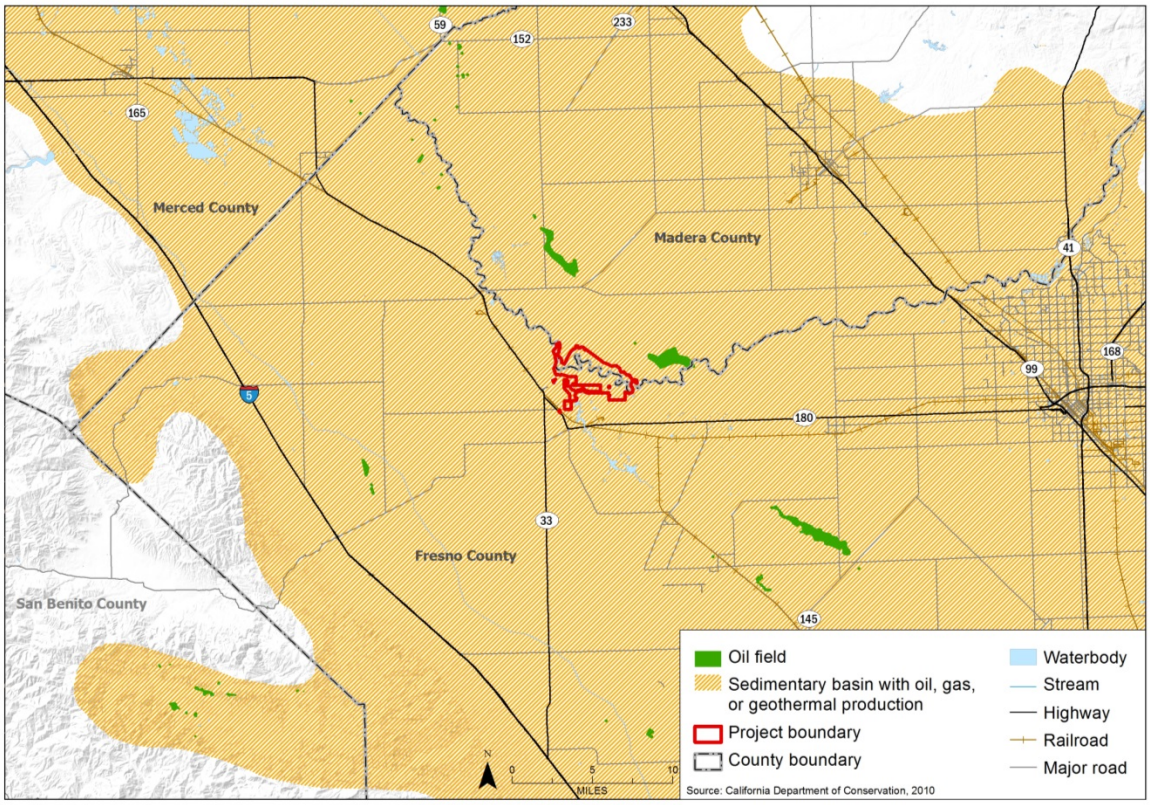

Figure 11-9.
Oil and Gas Fields in the Project Area and Vicinity

San Joaquin Valley Deformation and Subsidence

Regional deposition and deformation patterns of sediments in the San Joaquin Valley have been strongly controlled by recent tectonic activity (Bartow 1991). Quaternary deposits in the San Joaquin Valley are deformed into a broad, asymmetrical trough with its axis 12 to 19 miles west of the current course of the San Joaquin River (Lettis and Unruh 1991). Subsidence is probably due in part to the uplift and tilting of the Sierran block to the east and the Coast Ranges to the west, although the rate of valley subsidence is higher than that of Sierran uplift. Valley subsidence may also be due to sediment loading and compressional down warping or thrust loading from the Coast Ranges (Lettis and Unruh 1991).

Valley subsidence is also known to be occurring in some areas because of groundwater pumping, hydrocompaction, pumping from oil and gas fields, and oxidation of soils with high organic content. Of these factors, aquifer-system compaction by groundwater pumping has caused the largest magnitude and areal extent of land subsidence in the San Joaquin Valley (Sneed et al. 2013). Total subsidence near Mendota Pool reached nearly 9 feet by 2001 as compared to 1935 levels. Subsidence rates were greatest in the 1950s, with an average rate for areas near Mendota Pool of 4.4 inches per year (in/year), between 1953 and 1957. Subsidence rates near Mendota Pool have been reduced in more recent years with subsidence rates averaging 0.44 in/year between 1997 and 2001 and

0.04 in/year between 2003 and 2008 (Sneed et al. 2013). (Subsidence is also discussed in Chapter 13.0, "Hydrology – Groundwater" and Chapter 14.0, "Hydrology - Surface Water Resources and Water Quality.")

Seismicity

Active faults are recognized on the west side of the San Joaquin Valley (Figure 11-10). Most of these faults are part of a series of buried thrust faults (blind faults) that separate the Central Valley from the Coast Ranges. The Great Valley thrust system comprises at least 14 segments over a length of more than 300 miles, although precise locations of surface traces are not well documented because these faults do not rupture to the surface (USGS 1996). The Great Valley thrust system is thought to accommodate a nominal 0.02 to 0.06 in/year of motion (CGS 2002c, USGS 1996). The closest segment to the Project area is the Panoche Segment, Great Valley Segment 10, which is located about 19 miles to the southwest (Figure 11-10).

Seismicity in the Project area and vicinity is dominated by ground shaking related to movement on the buried thrust faults mapped along the west side of the San Joaquin Valley that separate the Sierran Block from the Coast Ranges block (Figure 11-10). The closest of these faults is about 19 miles to the southwest. Therefore, surface fault rupture is not a significant hazard for the Project area. Figure 11-11 shows historic earthquake epicenters in this part of California. No earthquakes with a magnitude greater than 6.0 have occurred within about 38 miles of the site. Figure 11-12 shows that the calculated peak horizontal ground acceleration that has a 2 percent probability of exceedance in 50 years is 0.3 to 0.4 g (expressed as a fraction of the acceleration due to Earth's gravity). The horizontal acceleration pattern shown reflects movement on Coast Ranges faults.

Ground Shaking and Liquefaction Hazards

Although a fault rupture can cause significant damage along its narrow surface trace, earthquake damage is mainly caused by strong, sustained ground shaking (Working Group on California Earthquake Probabilities [WG02] 2003). Seismic ground shaking can cause soils and unconsolidated sediments to compact and settle. If compacted soils or sediments are saturated, pore water pressure increases during earthquake shaking and water can be forced upward to the ground surface, forming sand boils or mud spouts. Increased pore pressures also lead to a reduction in shear strength of the sediments such that they may behave like a viscous fluid. This soil deformation, called liquefaction, may cause minor to major damage to buildings and infrastructure. Earthquake ground shaking hazard potential is low in most of the San Joaquin Valley and Sierra Nevada foothills (California Seismic Safety Commission [CSSC] 2003). Although the San Joaquin Valley is not considered to be a high-risk liquefaction area because of its generally low earthquake and ground shaking hazard risk, it can be assumed that some liquefaction risk exists throughout the valley in areas where unconsolidated sediments and a high water table coincide, such as near rivers and in wetland areas (Merced County 2007).

Hazard Due to Dam Break Inundation

The entire Project area and surrounding portion of the central San Joaquin Valley are in an area of potential inundation if either Friant or Pine Flat dams fail (Figure 11-13).

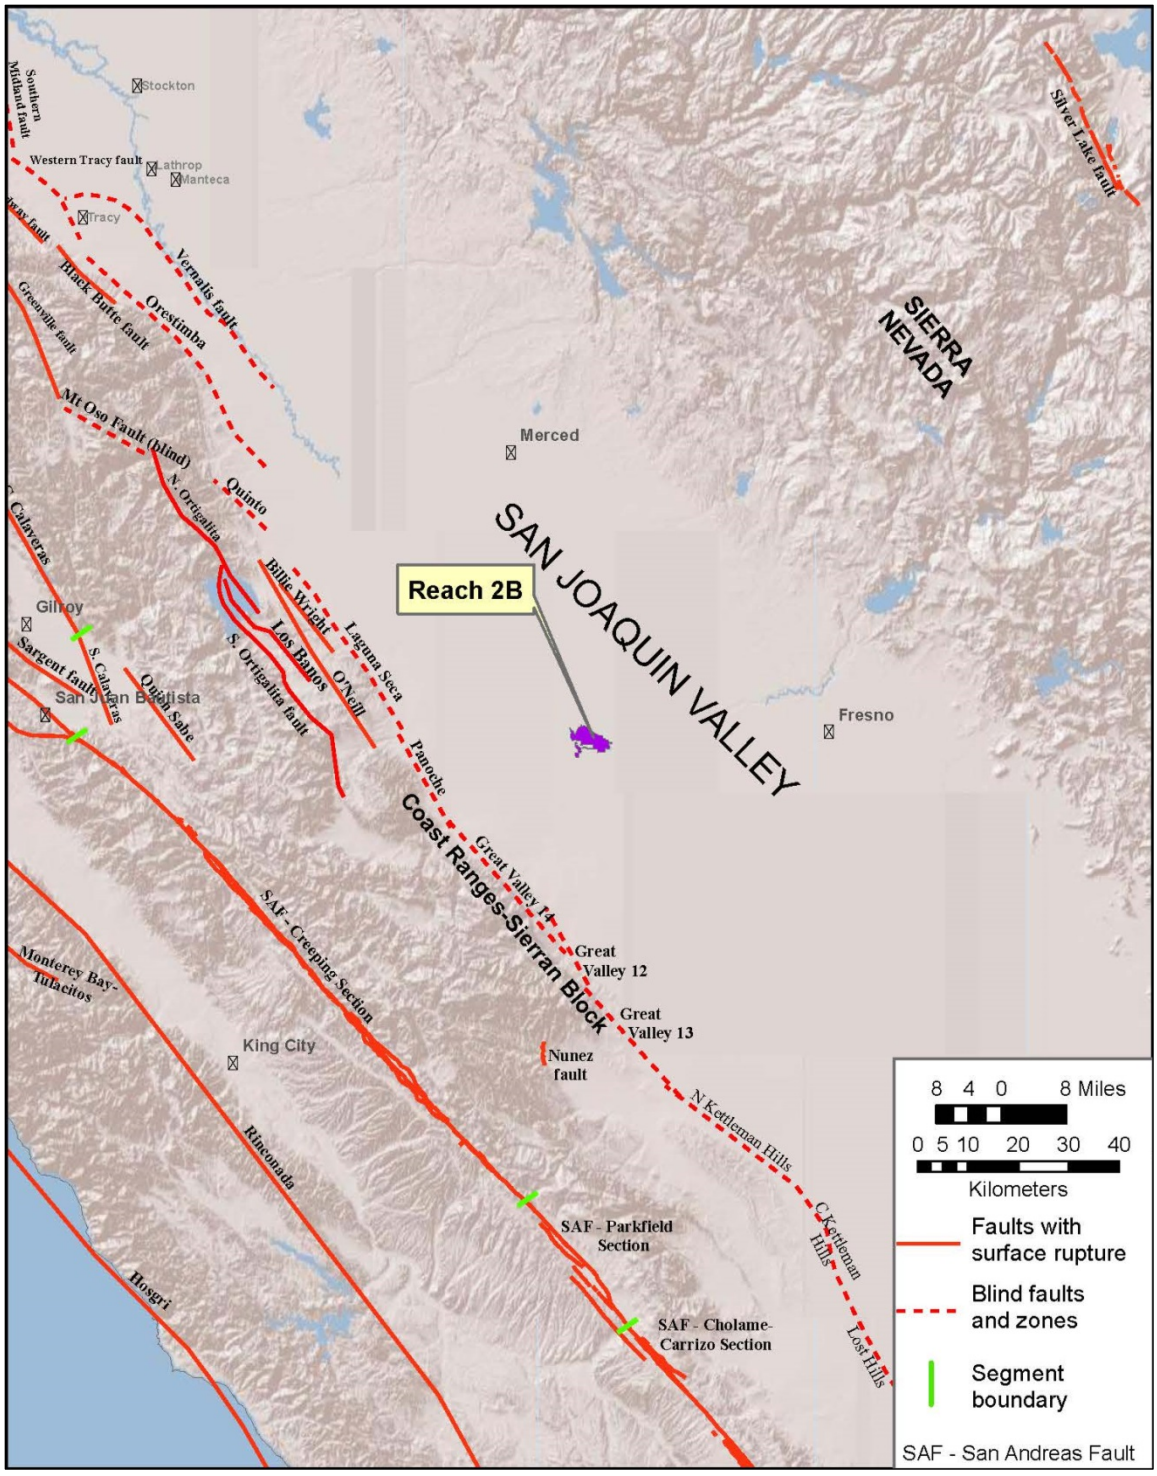

Figure 11-10.

11.2 Regulatory Setting

This section presents applicable Federal, State, and local laws and regulations associated with geology and soils in the Project area.

11.2.1 Federal

Federal regulations associated with geology and soils in the Project area include the Clean Water Act (CWA) and National Pollutant Discharge Elimination System (NPDES) program, as well as the National Flood Insurance Program, which regulates construction of levees and other flood-related activities.

Clean Water Act Section 402

(See Chapter 14.0, "Hydrology - Surface Water Resources and Water Quality.") CWA Section 402 is directly relevant to excavation and grading activities that may occur during restoration and other activities which may affect geology and soils in the Project area.

National Flood Insurance Program Regulations

(See Chapter 12.0, "Hydrology – Flood Management.") Criteria in 44 Code of Federal Regulations (CFR) 65.10 apply to Mapping of Areas Protected by Levee Systems and to standards for levee design and performance.

11.2.2 State of California

Several codes and acts are in place in the State that may pertain to activities affecting geology and soils in the Project area.

Alquist-Priolo Earthquake Fault Zoning Act

California's Alquist-Priolo Earthquake Fault Zoning Act (Pub. Resources Code, § 2621 et seq.), originally enacted in 1972 as the Alquist-Priolo Special Studies Zones Act, and renamed in 1994, is intended to reduce the risk to life and property from surface fault rupture during earthquakes. The Alquist-Priolo Act prohibits the location of most types of structures intended for human occupancy across the traces of active faults, and strictly regulates construction in the corridors along active faults (earthquake fault zones). However, no active faults are mapped within the Project area (Jennings and Bryant, 2010).

California Building Standards Code

California's minimum standards for the design and construction of buildings, associated facilities, and equipment are given in the California Code of Regulations. Many of the applicable standards are found in the California Building Standards Code (Cal. Code Regs., tit. 24); other standards applicable to buildings are given in Titles 8, 19, 21, and 25 of the California Code of Regulations. Design and construction must satisfy these requirements.

Surface Mining and Reclamation Act

The California Surface Mining and Reclamation Act of 1975 (SMARA) (Pub. Resources Code, § 2710 et seq.) addresses surface mining. Activities subject to SMARA include, but are not limited to mining of minerals, gravel, and borrow material. SMARA applies to an individual or entity that would disturb more than 1 acre or remove more than 1,000 cubic yards of material through surface mining activities, including the excavation of borrow pits for soil material. SMARA also mandated that the State Geologist make an inventory, by county, of mineral resources of statewide and regional significance.

11.2.3 Regional and Local

Local policies and plans in the Project area may relate to implementation of project alternatives potentially affecting geology and soils.

County General Plans

As required by state law, counties in the Project area have developed their own general plans. At a minimum, these documents must address the topics of land use, transportation, housing, conservation, open space, noise, and safety. These documents serve as statements of county goals, policies, standards, and implementation programs for the physical development of a county.

Fresno County General Plan

The Fresno County General Plan Policy Document (Fresno County 2000) outlines several policies for geological resources and/or geological hazards.

- Policy OS-J.9 requires that the location of significant geological resources is considered prior to approval of new development.
- Policy HS-D.3 requires that a soil engineering and geologic-seismic analysis is performed in areas prone to geologic or seismic hazards.
- Policy HS-D.4 requires that structures are designed in accordance with relevant professional standards to minimize damage or loss and to minimize risk to public safety.

Madera County General Plan

The Madera County General Plan Policy Document (Madera County 1995) outlines several policies for geological resources.

- Policy 5.G.1 protects geological resources from incompatible development.
- Policies 6.A.1 to 6.A.4 address seismic and geological hazards.

11.3 Environmental Consequences and Mitigation Measures

11.3.1 Impact Assessment Methodology

The analysis presented in this section is qualitative and based on the general information on geology, soils, mineral resources, seismicity and neotectonics, and geomorphology documented for the region, as previously described. The analysis is also based on a review of published geologic and soils information for the Project area, and professional judgment, in accordance with the current standard of care for geotechnical engineering and engineering geology. The evaluation of impacts on geologic and soil resources considers how proposed changes associated with Project alternatives would affect these resources in Reach 2B.

Impacts to geologic and soil resources that could result from Project construction and operation were evaluated qualitatively based on expected construction practices, materials, locations, and duration of Project construction and related activities, as well as project operations including the effects of modified San Joaquin River flows. The potential loss of geologic and soil resources resulting from implementation of Project alternatives is also evaluated qualitatively. The effect of the Project on the San Joaquin River fluvial geomorphology including bank erosion, channel migration, sedimentation, scour, and changes in the river channel substrate are addressed in Chapter 14, "Hydrology - Surface Water Resources and Water Quality."

Site geology has been evaluated to identify the potential for adverse effects resulting from failure of engineered structures, such as dams, levees, and bifurcations, caused by adverse geologic conditions. The following geologic and soil conditions could affect engineered structures that are part of the Project:

- Unsuitable geologic foundation materials, including compressible soils, expansive soils, and levee under-seepage.
- Erosion of soils from around and beneath structures and their foundations.

- Seismic conditions, including fault rupture, strong ground motion, seismic-induced liquefaction, lateral spreading, settlement, and slope failure.

Impacts to existing infrastructure caused by adverse geologic conditions exacerbated by implementation of the Project were also evaluated qualitatively.

Consistent with the general program-wide design strategies identified in the SJRRP, the analysis assumes the following:

- A geotechnical and engineering geologic study would guide the final site-specific design.
- Earthwork would be designed and conducted in accordance with all relevant requirements of U.S. Department of the Interior, Bureau of Reclamation (Reclamation) design standards including Design Standards No. 3, Chapter 12, General Structural Considerations.
- All structures would be designed consistent with Reclamation design standards or equivalent standards, for example U.S. Army Corps of Engineers (Corps) engineering design standards EM 1110-2-2000 Concrete for Civil Works Structures, EM 1110-2-2100 Stability Analysis of Concrete Structures, EM 1110-2-2705 Structural Design of Closure Structures for Local Flood Protection Projects.
- Expansive soil hazards can be addressed through overexcavation and replacement with nonexpansive fill, amendment, or other measures consistent with Reclamation design standards.
- Corrosive soil hazards can be addressed by overexcavation and replacement with noncorrosive fill, by use of corrosion-protected materials, or by other measures consistent with Reclamation design standards.
- Construction would proceed in accordance with requirements of a Stormwater Pollution Prevention Plan (SWPPP).
- Post-construction soil erosion hazard would be addressed by overexcavation and replacement with non-erosive engineered fill, or by the use of geosynthetics, vegetation, riprap, or other suitable measures consistent with Reclamation design standards.

11.3.2 Significance Criteria

The Project is evaluated in accordance with the Geology and Soils section of Appendix G of the California Environmental Quality Act (CEQA) Environmental Checklist and professional judgment on anticipated impacts on existing geologic and soil resources. Under the National Environmental Policy Act (NEPA), effects must be evaluated in terms of their context and intensity. These factors have been considered when applying the State CEQA Guidelines in Appendix G. Impacts associated with Project implementation have been determined to be significant if they would do any of the following:

- Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:
  - Rupture of a known earthquake fault.
  - Strong seismic ground shaking.
  - Seismic-related ground failure, including liquefaction.
  - Landslides.
- Result in substantial soil erosion or the loss of topsoil.
- Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the Project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse.
- Be located on expansive soil, as defined in Table 18-1-B of the 1994 Uniform Building Code, creating substantial risks to life or property.
- Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the State.
- Result in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan.
- Cause changes in conditions resulting in destabilization of existing infrastructure, such as levees, dams, other structures.
- Cause a proposed structure to fail, exposing people, existing infrastructure, and environmental, economic or cultural resources to potential substantial adverse effects.

11.3.3 Impacts and Mitigation Measures

This section provides an evaluation of direct and indirect effects of the Project Alternatives on geologic and soils resources. The analysis considers the short-term construction phase as well as the long-term operational phase. Table 11-4 provides a summary of environmental concerns by resource type or hazard.

This section includes analyses of potential effects relative to No-Action conditions in accordance with NEPA and potential impacts compared to existing conditions to meet CEQA requirements. The analysis is organized by Project alternative with specific impact topics numbered sequentially under each alternative.

With respect to geologic and soils resources, the environmental impact issues and concerns are:

1. Effects on Mineral and Soil Resources.
2. Soil Erosion Effects.
3. Adverse Soil Conditions.
4. Adverse Seismicity Effects.

Table 11-4.
Summary of Environmental Concerns

Resource or Hazard	Construction Phase (Short-Term Effects)	Operational Phase (Long-Term Effects)
Mineral resources	None	None
Soil resources	Potential effects	Potential long-term effects
Ground subsidence	None	Project designed for resource/hazard
Expansive soils	None	None
Corrosive soils	None	Project designed for resource/hazard
Collapsible soils	None	None
Difficult excavation	None	None
Soil erosion	Project designed for resource/hazard	Project designed for resource/hazard
Surface fault rupture	None	None
Seismic ground shaking	Unlikely during construction period	Project designed for resource/hazard
Liquefaction	Unlikely during construction period	Project designed for resource/hazard
Lateral spreading	Unlikely during construction period	Project designed for resource/hazard
Seismically induced flooding	Unlikely during construction period	Potential long-term effects
Landslide and rockfall	None	None
Subsurface gas	None	None

Note: Several hazards are unlikely to occur during the relatively short construction period. Nevertheless, they are included because they could theoretically be experienced during construction.

Other geologic and soils resource-related issues covered in the Program Environmental Impact Statement/Report (PEIS/R) are not covered here because they are programmatic in nature and/or are not relevant to the Project area.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. (See Section 2.2.3 for a detailed description of the No-Action Alternative.) However, other proposed actions under the SJRRP would be implemented, including habitat restoration, augmentation of river flows, and reintroduction of salmon. Without the Project in Reach 2B, however, these Program-level activities would not achieve full Settlement goals. This section provides an analysis of the No-Action Alternative. The analysis is a comparison to existing conditions, and no mitigation is required for No-Action.

Impact GEO-1 (No-Action Alternative): *Effects on Mineral and Soil Resources*. Under the No-Action Alternative, the Project would not be implemented and there would be no changes to existing geologic and soils conditions in the Project area as a result of construction activities or the placement of new Project facilities. As a result, there would be **no impact** on existing geologic and soils resources due to Project construction. (Potential impacts due to changes in erosion and deposition rates are discussed below.)

Impact GEO-2 (No-Action Alternative): *Soil Erosion Effects*. Under the No-Action Alternative, the Project would not be implemented and there would be no new construction within Reach 2B. The No-Action Alternative would maintain the existing

levee alignments and heights and maximum conveyance would continue to be limited to the existing capacity. As a result, there would be no erosion impacts related to or affecting new Reach 2B structures. However, compared to existing conditions (i.e., pre-Interim Flow conditions as of July 2009), the Program would implement changes to the management of discharges into the San Joaquin River from Friant Dam and these flows could affect sediment transport conditions within Reach 2B. Recent sediment continuity studies have predicted that sand inputs from Reach 2A under Restoration Flows would likely result in net deposition in the upper segment of Reach 2B and potentially down to the Mendota Pool. Net deposition also occurs in Reach 2B under existing conditions (SJRRP 2011, page 10-34).

Compared to existing conditions, soil erosion and deposition rates could change with implementation of Restoration Flows by the Program; however, maximum conveyance in Reach 2B would continue to be limited to the existing capacity and the reach would continue to experience net deposition. As a result, impacts to soil resources as a result of erosion and deposition within Reach 2B would be **less than significant**.

Impact GEO-3 (No-Action Alternative): *Adverse Soil Conditions*. Under the No-Action Alternative, the Project would not be implemented and there would be no new construction within Reach 2B. As a result, potentially corrosive soils or potential ground subsidence within Reach 2B would not impact Project structures. Compared to existing conditions, potential impacts to existing structures due to potentially corrosive soils or potential ground subsidence would remain unchanged and there would be no increase in risk that existing or proposed structures would fail as a result of adverse soil conditions. Therefore, there would be **no impact.**

Impact GEO-4 (No-Action Alternative): *Adverse Seismicity Effects*. Under the No-Action Alternative, the Project would not be implemented and there would be no new construction within Reach 2B. As a result, seismicity effects (e.g., seismic ground shaking, liquefaction, lateral spreading, and seismically induced flooding) would not impact Project structures. Compared to existing conditions, potential impacts to existing structures as a result of seismicity effects would remain unchanged. The likelihood of seismicity affecting the Project area would remain unchanged under this or any of the action alternatives and there would be no increase in risk that existing structures would fail as a result of these potential seismicity effects. Therefore, there would be **no impact**.

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

Alternative A would include construction of Project facilities capable of conveying up to 4,500 cfs including a Compact Bypass channel, a new levee system encompassing the river channel with a narrow floodplain, and the South Canal. Other key features include construction of the Mendota Pool Dike (separating the San Joaquin River and Mendota Pool), a fish barrier below Mendota Dam, and the South Canal bifurcation structure and fish passage facility, modification of the San Mateo Avenue crossing, and the removal of the San Joaquin River control structure at the Chowchilla Bifurcation Structure. (See Section 2.2.5 for a detailed description of the Alternative A.) No construction activities are proposed at or near Mendota Dam, which falls outside the Project boundary.

Construction activity is expected to occur intermittently over an approximate 132-month timeframe.

Impact GEO-1 (Alternative A): *Effects on Mineral and Soil Resources*. Compared to the No-Action Alternative, Project construction for Alternative A would include the Compact Bypass, the South Canal, a 3,000-foot-wide floodplain, and levees along both sides of the floodplain. Currently soils within the footprints of these structures (i.e., the Compact Bypass, South Canal, and narrow floodplain levees) include about 1,410 acres that are farmed. Also, the approximately 3,000-foot-wide floodplain area between the two new levees would be unavailable for farming many current crops under Alternative A, but a portion of the floodplain would be available for annual crops, pasture, or floodplain-compatible permanent crops. Areas where there would be temporary construction impacts include construction office sites, equipment maintenance and parking areas, and material storage areas. It is estimated that approximately 62 acres would temporarily be impacted by this construction; most of these areas are currently in agricultural production. A more detailed discussion of impacts to farming is presented in Chapter 16, "Land Use Planning and Agricultural Resources."

Borrow material would primarily be required for the construction of the levees, but it may also be used in the construction of other structures for foundation or backfill material. Levees may be constructed entirely of local borrow material, a mix of local and imported borrow material, or just imported borrow material. Borrow locations would be determined after a geotechnical exploration of potential local borrow areas is complete (see Section 2.2.4). It is estimated that up to 350 acres of land would be needed for borrow areas. Some of the soils excavated to construct the Compact Bypass and the South Canal might be used for levee construction, and if this is possible, then the size of the borrow areas may be reduced. Excavation of borrow materials would be done in accordance with Reclamation design standards permit requirements.

When comparing Alternative A to existing conditions, impacts to soil resources from construction activities would be similar to those described above (i.e., the comparison of Alternative A to the No-Action Alternative). Because borrow material would be excavated in accordance with Reclamation guidelines designed to be protective of soil resources, impacts to soil resources would be **less than significant**.

Impact GEO-2 (Alternative A): *Soil Erosion Effects*. Compared to the No-Action Alternative, short-term increases in erosion could occur during construction as a result of disturbed soils. However, Reclamation would prepare and implement a SWPPP that complies with applicable Federal NPDES regulations concerning construction activities. Implementation of erosion control best management practices (BMPs) consistent with the Project's construction SWPPP would minimize soil erosion during construction.

Under Alternative A, the long-term flow conveyance capacity of Reach 2B would increase to 4,500 cfs and Reach 2B would receive increased flows that could lead to changes in sediment transport conditions within the new Compact Bypass, the floodplain, and the South Canal. However, standard erosion protection measures, such as revetment, and proper hydraulic engineering design would be implemented to minimize erosion near

Project structures and levees (see Section 2.2.4). Proper engineering design of the new Project features, such as larger culverts that can pass higher flows with reduced scour, would minimize potential increases in soil erosion in the Project area following construction.

When comparing Alternative A to existing conditions, impacts from soil erosion effects would be similar to those described above (i.e., the comparison of Alternative A to the No-Action Alternative). As a result, the impact on erosion would be **less than significant**.

Impact GEO-3 (Alternative A): *Adverse Soil Conditions*. Compared to the No-Action Alternative, the Project design under Alternative A would include new earth structures, such as the Compact Bypass, South Canal, and levees, as well as other smaller reinforced concrete structures such as the South Canal bifurcation structure, fish passage facility, and fish screen; grade control structures in the Compact Bypass; and a fish barrier below Mendota Dam in Reach 3. Adverse soil conditions could negatively affect the long-term stability of Project features.

Under-seepage, water that seeps laterally by travelling under a dam or levee section, can occur when structures are underlain by permeable native soils. This may cause instability in the structures built on these soils. Seepage control measures would be included, as part of the Project, in areas where under-seepage is likely to affect adjacent land uses. Seepage control measures could include slurry walls, interceptor drains, seepage wells, seepage berms, land acquisition (fee title or seepage easements), and other measures that can be implemented within the Project area (see Section 2.2.4).[5]

Other adverse soil conditions within Reach 2B could include soils corrosive to buried concrete and/or steel and soils susceptible to consolidation and the related settlement of overlying structures. Site specific geotechnical exploration, testing, and analysis prior to final design would allow for the characterization of the site soils and appropriate design of all proposed structures such that potentially corrosive soils or subsidence conditions should not impact Project facilities. All design work would be completed in general accordance with Reclamation design standards, applicable design codes, and commonly accepted industry standards (see Section 2.2.4).

When comparing Alternative A to existing conditions, impacts from adverse soil conditions would be similar to those described above (i.e., the comparison of Alternative A to the No-Action Alternative). As a result, impacts of potentially adverse soils within Reach 2B on Project structures would be **less than significant**.

[5] A slurry wall is a construction technique to reinforce areas of soft earth that are near open water or a high groundwater table with a mixture of soil, bentonite, and cement. Interceptor drains are buried perforated pipes which intercept groundwater and redirect it to a discharge point. Because the drains have lower resistance to flow, the groundwater table can be kept artificially low in areas near the pipe. Seepage wells are groundwater wells that are used to pump and draw down the water table where seepage is occurring. Seepage berms are berms placed on the landside of a levee to add additional weight and width to the levee to counteract seepage.

Impact GEO-4 (Alternative A): *Adverse Seismicity Effects*. Compared to the No-Action Alternative, potential impacts to existing structures as a result of seismicity effects would remain unchanged. However, Reach 2B would be modified under Alternative A with the construction of the Compact Bypass, levees on the north and south sides of the expanded floodplain, the South Canal, and several other structures. Each of these structures would be built according to Reclamation design standards, the Corps engineering design standards, or equivalent standards (see Section 2.2.4). As a result, the new structures would be designed as necessary to withstand seismic forces, and foundations would be designed to protect the structure from the deleterious effects of strong ground shaking, liquefaction, and lateral spreading. The potential for flooding related to seismically induced dam failure cannot be lessened through the design of Project facilities; however, the Project would not include development that would put additional people at risk or increase flood risk at occupied structures.

Compared to existing conditions, potential impacts to existing structures as a result of seismicity effects would remain unchanged. The likelihood of seismicity affecting the existing Reach 2B area would remain unchanged under this or any of the other alternatives. Proposed structures would be designed to withstand seismic forces and protect against the deleterious effects of liquefaction and lateral spreading. Therefore, there would be **no impact.**

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Alternative B would include construction of Project features capable of conveying up to 4,500 cfs including a Compact Bypass channel, a new levee system with a wide, consensus-based floodplain encompassing the river channel, and the Compact Bypass Bifurcation Structure with fish passage facility. Other key features include construction of a fish passage facility at the San Joaquin River control structure at the Chowchilla Bifurcation Structure, the re-route of Drive 10 ½ (across the Compact Bypass control structure), and removal of the San Mateo Avenue crossing. (See Section 2.2.6 for a detailed description of the Alternative B.) No construction activities are proposed at or near Mendota Dam, which falls outside the Project boundary. Construction activity is expected to occur intermittently over an approximate 157-month timeframe.

Impact GEO-1 (Alternative B): *Effects on Mineral and Soil Resources*. Compared to the No-Action Alternative, Project construction for Alternative B would include the Compact Bypass and an approximately 4,200-foot-wide floodplain with levees along both sides of the floodplain. Currently soils within the footprints of these two areas (Compact Bypass and wide, consensus-based floodplain levees) include about 1,600 acres that are farmed. A portion of this area would include a mixture of active and passive riparian and floodplain habitat restoration and would no longer be available for farming. Other areas where there would be temporary construction impacts include construction office sites, equipment maintenance and parking areas, and materials storage areas. It is estimated that approximately 60 acres would temporarily be impacted by this construction; most of these areas are currently in agricultural production. A more detailed discussion of impacts to farming is presented in Chapter 16, “Land Use Planning and Agricultural Resources.”

Borrow material would primarily be required for the construction of the levees, but it may also be used in the construction of other structures for foundation or backfill material. Levees may be constructed entirely of local borrow material, a mix of local and imported borrow material, or just imported borrow material. Borrow locations would be determined after a geotechnical exploration of potential local borrow areas is complete; the exploration would determine the suitability of local soils for use as borrow material (see Section 2.2.4). It is estimated that up to 350 acres of land would be needed for borrow areas. Some of the soils excavated to construct the Compact Bypass might be used for levee construction, and if this is possible, then the size of the borrow areas may be reduced. Excavation of borrow materials would be done in accordance Reclamation design standards and permit requirements.

When comparing Alternative B to existing conditions, impacts to soil resources from construction activities would be the same as those described above (i.e., the comparison of Alternative B to the No-Action Alternative). Because borrow material would be excavated in accordance with Reclamation guidelines designed to be protective of soil resources, impacts to soil resources would be **less than significant**.

Impact GEO-2 (Alternative B): *Soil Erosion Effects*. Compared to the No-Action Alternative, short-term increases in erosion could occur during construction as a result of disturbed soils. However, Reclamation would prepare and implement a SWPPP that complies with applicable Federal NPDES regulations concerning construction activities. Implementation of erosion control BMPs consistent with the Project's construction SWPPP would minimize soil erosion during construction.

Under Alternative B, the long-term flow conveyance capacity of Reach 2B would increase to 4,500 cfs and Reach 2B would receive increased flows that could lead to changes in sediment transport conditions within the new Compact Bypass, the floodplain, and adjacent to new structures. However, standard erosion protection measures such as revetment and proper hydraulic engineering design would be implemented to minimize erosion near Project structures and levees (see Section 2.2.4). Proper engineering design of the new Project features would minimize potential increases in soil erosion in the Project area following construction.

When comparing Alternative B to existing conditions, impacts from soil erosion effects would be similar to those described above (i.e., the comparison of Alternative B to the No-Action Alternative). As a result, the impact on erosion would be **less than significant** due to construction of Alternative B.

Impact GEO-3 (Alternative B): *Adverse Soil Conditions*. Compared to the No-Action Alternative, the Project under Alternative B would include new earth structures such as the Compact Bypass and levees, as well as other reinforced concrete structures such as the Compact Bypass Bifurcation Structure, fish passage facility, and grade control structures in the Compact Bypass. Adverse soil conditions could negatively affect the long-term stability of Project features.

Under-seepage, water that seeps laterally by travelling under a dam or levee section, can occur when structures are underlain by permeable native soils. This may cause instability in the structures built on these soils. Seepage control measures (as described above for Impact GEO-3 [Alternative A]) would be included, as part of the Project, in areas where under-seepage is likely to affect adjacent land uses (see Section 2.2.4).

Other adverse soil conditions within Reach 2B could include soils corrosive to buried concrete and/or steel and soils susceptible to consolidation and the related settlement of overlying structures. Site-specific geotechnical exploration, testing, and analysis prior to final design would allow for the characterization of the site soils and appropriate design of all proposed structures such that potentially corrosive soils or subsidence conditions should not impact Project facilities. All design work would be completed in general accordance with Reclamation Design Standards, applicable design codes, and commonly accepted industry standards (see Section 2.2.4).

When comparing Alternative B to existing conditions, impacts from adverse soil conditions would be similar to those described above (i.e., the comparison of Alternative B to the No-Action Alternative). As a result, impacts of potentially adverse soils within Reach 2B on Project structures would be **less than significant**.

Impact GEO-4 (Alternative B): *Adverse Seismicity Effects*. Compared to the No-Action Alternative, potential impacts to existing structures as a result of seismicity effects would remain unchanged. However, Reach 2B would be modified under Alternative B with new construction of the Compact Bypass and bypass control structure, levees on the north and south sides of the expanded floodplain, and other structures. Each of these structures would be built according to Reclamation design standards, the Corps engineering design standards, or equivalent standards (see Section 2.2.4). As a result, the new structures would be designed as necessary to withstand seismic forces, and foundations would be designed to protect the structure from the deleterious effects of liquefaction and lateral spreading. The potential for flooding related to seismically induced dam failure cannot be lessened through the design of Project facilities; however, the Project would not include development that would put additional people at risk or increase flood risk at occupied structures.

Compared to existing conditions, potential impacts to existing structures as a result of seismicity effects would remain unchanged. The likelihood of seismicity affecting the existing Reach 2B area would remain unchanged under this or any of the other alternatives. Proposed structures would be designed to withstand seismic forces and protect against the deleterious effects of liquefaction and lateral spreading. Therefore, there would be **no impact.**

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Alternative C would include construction of Project features including Fresno Slough Dam, a new levee system with a narrow floodplain encompassing the river channel, and the Short Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the Short Canal control structure and fish screen, the Chowchilla Bifurcation Structure fish passage facility, modification of San

Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. (See Section 2.2.7 for a detailed description of the Alternative C.) Construction activity is expected to occur intermittently over an approximate 133-month timeframe.

Impact GEO-1 (Alternative C): *Effects on Mineral and Soil Resources*. Compared to No-Action, Project construction for Alternative C would include the new Fresno Slough Dam, adjacent Short Canal, floodplain, and levees along both sides of the floodplain. The Fresno Slough Dam would be constructed in an area that is not farmed. Currently soils within the footprint of the new levees and South Canal include about 1,170 acres that are farmed. These areas would no longer be available for farming. The approximately 3,000-foot-wide area between the two new floodplain levees would be revegetated as part of the habitat restoration program and would not be available for farming under Alternative C. Other areas where there would be temporary construction impacts include construction office sites, equipment maintenance and parking areas, and materials storage areas. It is estimated that approximately 62 acres would temporarily be impacted by this construction; most of these areas are currently in agricultural production. A more detailed discussion of impacts to farming is presented in Chapter 16, "Land Use Planning and Agricultural Resources."

Borrow material would primarily be required for the construction of the levees, but it may also be utilized in the construction of other structures for foundation or backfill material. Levees may be constructed entirely of local borrow material, a mix of local and imported borrow material, or just imported borrow material. Borrow locations would be determined after a geotechnical exploration of potential local borrow areas is complete; the exploration would determine the suitability of local soils for use as borrow material (see Section 2.2.4). It is estimated that up to 350 acres of land would be needed for borrow areas. Some of the soils excavated to construct the Short Canal might be used for levee construction, and if this is possible, then the size of the borrow areas may be reduced. Excavation of borrow materials would be done in accordance with Reclamation design standards and permit requirements.

When comparing Alternative C to existing conditions, impacts to soil resources from construction activities would be the same as those described above (i.e., the comparison of Alternative C to the No-Action Alternative). Because borrow material would be excavated in accordance with Reclamation guidelines designed to be protective of soil resources, impacts to soil resources would be **less than significant**.

Impact GEO-2 (Alternative C): *Soil Erosion Effects*. Compared to the No-Action Alternative, short-term increases in erosion could occur during construction as a result of disturbed soils. However, Reclamation would prepare and implement a SWPPP that complies with applicable Federal NPDES regulations concerning construction activities. Implementation of erosion control BMPs consistent with the Project's construction SWPPP would minimize soil erosion during construction.

Under Alternative C, the long-term flow conveyance capacity of Reach 2B would increase to 4,500 cfs and Reach 2B would receive increased flows that could lead to changes in sediment transport conditions within the floodplain and adjacent to structures.

However, standard erosion protection measures such as revetment and proper hydraulic engineering design would be implemented to minimize erosion near Project structures and levees (see Section 2.2.4). Proper engineering design of the new Project features would minimize potential increases in soil erosion in the Project area following construction.

When comparing Alternative C to existing conditions, impacts from soil erosion effects would be similar to those described above (i.e., the comparison of Alternative C to the No-Action Alternative). As a result, the impact on erosion would be **less than significant** due to construction of Alternative C.

Impact GEO-3 (Alternative C): *Adverse Soil Conditions*. Compared to the No-Action Alternative, the Project design under Alternative C would include new earth structures such as the floodplain and levees, as well as reinforced concrete structures such as the Fresno Slough Dam, fish passage facilities at Mendota Dam and Chowchilla Bypass, grade control structures downstream of Mendota Dam, Short Canal, and improved San Mateo Avenue crossing. Adverse soil conditions could negatively affect the long-term stability of Project features.

Under-seepage, water that seeps laterally by travelling under a dam or levee section, can occur when structures are underlain by permeable native soils. This may cause instability in the structures built on these soils. Seepage control measures (as described above for Impact GEO-3 [Alternative A]) would be included, as part of the Project, in areas where under-seepage is likely to affect adjacent land uses (see Section 2.2.4).

Other adverse soil conditions within Reach 2B could include soils corrosive to buried concrete and/or steel and soils susceptible to consolidation and the resultant settlement of overlying structures. Site specific geotechnical exploration, testing, and analysis prior to final design would allow for the characterization of the site soils and appropriate design of all proposed structures such that potentially corrosive soils or subsidence conditions should not impact Project facilities. All design work would be completed in general accordance with Reclamation Design Standards, applicable design codes, and commonly accepted industry standards (see Section 2.2.4).

When comparing Alternative C to existing conditions, impacts from adverse soil conditions would be similar to those described above (i.e., the comparison of Alternative C to the No-Action Alternative). As a result, impacts of potentially adverse soils within Reach 2B on Project structures would be **less than significant**.

Impact GEO-4 (Alternative C): *Adverse Seismicity Effects*. Compared to the No-Action Alternative, potential impacts to existing structures as a result of seismicity effects would remain unchanged. However, Reach 2B would be modified under Alternative C with construction of the Fresno Slough Dam, adjacent Short Canal, and floodplain and levees along both sides of the river, as well as several other structures. Each of these structures would be built according to Reclamation design standards, the Corps engineering design standards, or equivalent standards (see Section 2.2.4). As a result, the new structures would be designed as necessary to withstand seismic forces, and

foundations would be designed to protect the structure from the deleterious effects of liquefaction and lateral spreading. The potential for flooding related to seismically induced dam failure cannot be lessened through the design of Project facilities; however, the Project would not include development that would put additional people at risk or increase flood risk at occupied structures.

Compared to existing conditions, potential impacts to existing structures as a result of seismicity effects would remain unchanged. The likelihood of seismicity affecting the existing Reach 2B area would remain unchanged under this or any of the other alternatives. Proposed structures would be designed to withstand seismic forces and protect against the deleterious effects of liquefaction and lateral spreading. Therefore, there would be **no impact.**

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Alternative D would include construction of Project features including Fresno Slough Dam, a new levee system with a wide floodplain encompassing the river channel, and the North Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough Dam fish barrier, the North Canal bifurcation structure, fish passage facility, and fish screen, removal of the San Joaquin River control structure at the Chowchilla Bifurcation Structure, removal of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. (See Section 2.2.8 for a detailed description of the Alternative D.) Construction activity is expected to occur intermittently over an approximate 158-month timeframe.

Impact GEO-1 (Alternative D): ***Effects on Mineral and Soil Resources*****.** Compared to No-Action, Project construction for Alternative D would include the Fresno Slough Dam, floodplain and levees along both sides of the river and the North Canal. The Fresno Slough Dam would be constructed in an area that is not farmed. Currently soils within the footprint of the new levees and North Canal include about 1,900 acres that are farmed. Also, the approximately 4,200-foot-wide floodplain would be unavailable for farming many current crops under Alternative D, but a portion of the floodplain would be available for annual crops, pasture, or floodplain-compatible permanent crops. Other areas where there would be temporary construction impacts include construction office sites, equipment maintenance and parking areas, and materials storage areas. It is estimated that approximately 62 acres would temporarily be impacted by this construction; most of these areas are currently in agricultural production. A more detailed discussion of impacts to farming are presented in Chapter 16, “Land Use Planning and Agricultural Resources.”

Borrow material would primarily be required for the construction of the levees, but it may also be utilized in the construction of other structures for foundation or backfill material. Levees may be constructed entirely of local borrow material, a mix of local and imported borrow material, or just imported borrow material. Borrow locations would be determined after a geotechnical exploration of potential local borrow areas is complete; the exploration would determine the suitability of local soils for use as borrow material (see Section 2.2.4). It is estimated that up to 350 acres of land would be needed for borrow areas. Some of the soils excavated to construct the North Canal might be used for

levee construction, and if this is possible, then the size of the borrow areas may be reduced. Excavation of borrow materials would be done in accordance with Reclamation design standards and permit requirements.

When comparing Alternative D to existing conditions, impacts to soil resources from construction activities would be similar to those described above (i.e., the comparison of Alternative D to the No-Action Alternative). Because borrow material would be excavated in accordance with Reclamation guidelines designed to be protective of soil resources, impacts to soil resources would be **less than significant**.

Impact GEO-2 (Alternative D): *Soil Erosion Effects*. Compared to the No-Action Alternative, short-term increases in erosion could occur during construction as a result of disturbed soils. However, Reclamation would prepare and implement a SWPPP that complies with applicable Federal NPDES regulations concerning construction activities. Implementation of erosion control BMPs consistent with the Project's construction SWPPP would minimize soil erosion during construction.

Under Alternative D, the long-term flow conveyance capacity of Reach 2B would increase to 4,500 cfs and Reach 2B would receive increased flows that could lead to changes in sediment transport conditions within the expanded floodplain and adjacent to new structures. However, standard erosion protection measures such as revetment and proper hydraulic engineering design would be implemented to minimize erosion near Project structures and levees (see Section 2.2.4). Proper engineering design of the new Project features would minimize potential increases in soil erosion in the Project area following construction.

When comparing Alternative D to existing conditions, impacts from soil erosion effects would be similar to those described above (i.e., the comparison of Alternative D to the No-Action Alternative). As a result, the impact on erosion would be **less than significant** due to construction of Alternative D.

Impact GEO-3 (Alternative D): *Adverse Soil Conditions*. Compared to the No-Action Alternative, the Project design under Alternative D would include new earth structures such as the floodplain, levees, and North Canal, as well as reinforced concrete structures such as the Fresno Slough Dam, fish passage facilities at Mendota Dam, grade control structures downstream of Mendota Dam, and North Canal bifurcation structure, fish passage facility, and fish screen. Adverse soil conditions could negatively affect the long-term stability of Project features.

Under-seepage, water that seeps laterally by travelling under a dam or levee section, can occur when structures are underlain by permeable native soils. This may cause instability in the structures built on these soils. Seepage control measures (as described above for Impact GEO-3 [Alternative A]) would be included, as part of the Project, in areas where under-seepage is likely to affect adjacent land uses (see Section 2.2.4).

Other adverse soil conditions within Reach 2B could include soils corrosive to buried concrete and/or steel and soils susceptible to consolidation and the resultant settlement of

overlying structures. Site specific geotechnical exploration, testing, and analysis prior to final design would allow for the characterization of the site soils and appropriate design of all proposed structures such that potentially corrosive soils or subsidence conditions should not impact Project facilities. All design work would be completed in general accordance with Reclamation Design Standards, applicable design codes, and commonly accepted industry standards (see Section 2.2.4).

When comparing Alternative D to existing conditions, impacts from adverse soil conditions would be similar to those described above (i.e., the comparison of Alternative D to the No-Action Alternative). As a result, impacts of potentially adverse soils within Reach 2B on Project structures would be **less than significant**.

Impact GEO-4 (Alternative D): *Adverse Seismicity Effects*. Compared to the No-Action Alternative, potential impacts to existing structures as a result of seismicity effects would remain unchanged. However, Reach 2B would be modified under Alternative D with the construction of the Fresno Slough Dam, floodplain and levees along both sides of the river, and North Canal, and as well as several other structures. Each of these structures would be built according to Reclamation design standards, the Corps engineering design standards, or equivalent standards (see Section 2.2.4). As a result, the new structures would be designed as necessary to withstand seismic forces, and foundations would be designed to protect the structure from the deleterious effects of liquefaction and lateral spreading. The potential for flooding related to seismically induced dam failure cannot be lessened through the design of Project facilities; however, the Project would not include development that would put additional people at risk or increase flood risk at occupied structures.

Compared to existing conditions, potential impacts to existing structures as a result of seismicity effects would remain unchanged. The likelihood of seismicity affecting the existing Reach 2B area would remain unchanged under this or any of the other alternatives. Proposed structures would be designed to withstand seismic forces and protect against the deleterious effects of liquefaction and lateral spreading. Therefore, there would be **no impact.**

12.0 Hydrology - Flood Management

This chapter describes the environmental and regulatory settings for flood management and environmental consequences and mitigation, which could potentially be affected by implementation of Project alternatives.

12.1 Environmental Setting

The environmental setting for flood management includes a discussion of flood protection history in the San Joaquin River basin, flood management structures, and flood management operations and conditions. Much of the information presented in this section was obtained from the Upper San Joaquin River Basin Storage Investigation Initial Alternatives Report Information Report, Flood Damage Reduction Technical Appendix (U.S. Department of the Interior, Bureau of Reclamation [Reclamation] and California Department of Water Resources [DWR] 2005) and is summarized below.

12.1.1 Historical Perspective of Flood Protection in the San Joaquin River Basin

Historically, the San Joaquin River had insufficient capacity to carry heavy winter and spring flows generated by precipitation and/or snowmelt within its channel banks. Once flows exceeded channel capacities, the channels overflowed onto the surrounding countryside, forming vast floodplains. Velocities in overbank areas were greatly reduced from velocities in the channels reducing the sediment-carrying capacity of the water allowing material naturally eroded from mountain and foothill areas to drop out of suspension. In this way, over many years, the San Joaquin River built up its bed and formed natural levees composed of heavier, coarser material carried by flood flows. Finer material stayed in suspension much longer and dropped out when overflow water ponded in basins that developed east and west of the river. The higher elevation land formed by the natural levees attracted the first settlements in the Central Valley. In the early 1800s, settlers and Native Americans described the Sacramento and San Joaquin rivers as “miles wide” during flooding.

Early Flood Protection

Initial flood protection in the Central Valley developed in a piecemeal fashion with the construction of levees to protect local areas from flooding. Levees were typically constructed in response to a past flood, with little or no coordination between different localities. As the private levee system developed, the protection afforded by individual levees decreased because of the increased heights of floodwaters constrained between the levees. The increased flood danger led to competition between landowners to continually raise and strengthen levees by stages to protect local areas and direct floodwaters elsewhere.

By the early 1900s, it was evident that local efforts would not be adequate to provide flood protection to agricultural lands in the Sacramento River and San Joaquin River basins. In 1920, Colonel Robert Marshall, chief geographer for the U.S. Geological Survey (USGS), proposed a major water storage and conveyance plan to transfer water from Northern California to meet urban and agricultural needs of central and Southern California. This plan ultimately provided the framework for development of the Central Valley Project (CVP). Under the Marshall Plan, a dam would be constructed on the San Joaquin River near Friant to divert water north and south to areas in the eastern portion of the San Joaquin Valley, and provide flood protection to downstream areas. The diverted water would be a supplemental supply to relieve some of the dependency on groundwater that had led to overdraft in areas of the eastern San Joaquin Valley. Water in the Sacramento Valley would be collected, stored, and transferred to the San Joaquin Valley by a series of reservoirs, pumps, and canals.

In 1933, the California State Legislature approved the Central Valley Project Act, which authorized construction of initial features of the CVP, including Shasta Dam; Friant Dam; power transmission facilities from Shasta to Tracy; and the Contra Costa, Delta-Mendota, Madera, and Friant-Kern canals. However, the Great Depression prevented the State from financing the project so the State appealed to the Federal Government for assistance in constructing the CVP.

Congress appropriated funds and authorized construction of the CVP and construction began on October 19, 1937, with the Contra Costa Canal. Construction of Shasta Dam began in 1938 and was completed for full operation in 1949. Friant Dam, on the San Joaquin River, was also completed in 1949.

The Flood Control Act of 1944 authorized the Lower San Joaquin River and Tributaries Project. The project included constructing levees on the San Joaquin River below the Merced River, Stanislaus River, Old River, Paradise Cut, and Camp Slough. Construction was initiated on the Lower San Joaquin River and Tributaries Project in 1956. The Chowchilla and Eastside bypasses were constructed by the State as part of the Lower San Joaquin River Project.

12.1.2 Flood Management Structures

Friant Dam

Friant Dam is the principal flood damage reduction facility on the San Joaquin River and is operated to maintain combined releases to the San Joaquin River at or below a flow objective of 8,000 cubic feet per second (cfs). Several flood events, as described below, in the past few decades have resulted in flows greater than 8,000 cfs downstream from Friant Dam and, in some cases, flood damages resulted.

The existing Friant Dam is a 319-foot-tall concrete gravity dam with a crest length of 3,488 feet and a crest width of 20 feet. Millerton Lake, formed by Friant Dam, has a volume of 524 thousand acre-feet (TAF). The dam serves the dual purposes of storage for irrigation and flood management. The minimum operating storage of Millerton Lake is 130 TAF, resulting in active available conservation storage of about 390 TAF. The

minimum operating storage allows for diversion from dam outlets to the Friant-Kern Canal, Madera Canal and the San Joaquin River. During the rainy season of October through March up to 170 TAF of available storage space must be maintained for management of rain floods.

San Joaquin River

Except for a small area to the west and south of Fresno Slough, the Project area is located in a Federal Emergency Management Agency (FEMA) Special Flood Hazard Zone A (no base flood elevations have been determined). The area adjacent to Fresno Slough is designated as Zone AO (1-3 feet of flood depth).

Chowchilla Bypass and Chowchilla Bifurcation Structure

The flood control structure most relevant to Reach 2B is the Chowchilla Bypass and Chowchilla Bifurcation Structure, owned by DWR and the Central Valley Flood Protection Board (CVFPB) for the State of California. The Chowchilla Bypass begins at the Chowchilla Bifurcation Structure in the San Joaquin River and runs northwest, parallel to the San Joaquin River, to the confluence of the Fresno River, where the Chowchilla Bypass ends and essentially becomes the Eastside Bypass. The design channel capacity of the Chowchilla Bypass is 5,500 cfs. The bypass is constructed in highly permeable soils, and much of the initial flood flows infiltrate and recharge groundwater. The Chowchilla Bifurcation Structure is a gated structure that controls the proportion of flood flows between the Chowchilla Bypass and the San Joaquin River Reach 2B. The bifurcation structure has a drop (plunge pool) on the downstream side in both the San Joaquin River and Chowchilla Bypass, and has no fish passage facilities. The Chowchilla Bifurcation Structure is operated to keep flows in Reach 2B at a level less than 2,500 cfs because of channel design capacity limitations. Therefore, operating rules for the Chowchilla Bifurcation Structure are based on initial flow to the San Joaquin River and initial flow to the Chowchilla Bypass (McBain and Trush 2002). The intended design capacities for the various sections of the San Joaquin River reaches in the Project area are described in Table 12-1.

Mendota Dam

Mendota Dam is located at the confluence of the San Joaquin River and Fresno Slough. Mendota Pool is a small reservoir, with approximately 8,000 acre-feet of storage, created by Mendota Dam. The Mendota Pool does not provide any appreciable flood storage. The water surface elevation in the pool is maintained by a set of gates and flashboards that are manually opened/removed in advance of high-flow conditions. This process lowers the water level in the pool for passing high flows to reduce seepage impacts to adjacent lands, but hinders distribution of flows into the canals.

Over time, the Mendota Pool has partially filled with sediment during infrequent high-flow releases from Friant Dam. During times of high flows, some unknown portion of this sediment is able to flush and route downstream when flashboards have been removed, restoring much of the Mendota Pool storage capacity. If the flashboards are not removed before a high-flow event from either the San Joaquin River or Kings River via Fresno Slough, the increased water surface elevations cause seepage problems on upstream and adjacent properties. Additionally, there have been recurring problems with

water seeping under Mendota Dam, threatening the structural integrity of the dam. The Mendota Pool is drained every other year to inspect Mendota Dam footings.

Table 12-1.
Design Capacities of San Joaquin River and Chowchilla Bypass Within the Project Area and Vicinity

Reach	Upstream Extent	Downstream Extent	Levee Type[a]	Design Capacity (cfs)[b]
Reach 2A	Gravelly Ford	Chowchilla Bifurcation Structure	Project	8,000
Reach 2B	Chowchilla Bifurcation Structure	Mendota Dam	Non-project	2,500
Reach 3	Mendota Dam	Sack Dam	Non-project	4,500
Reach 4A	Sack Dam	Sand Slough Control Structure	Non-project	4,500
Kings River North	Fresno Slough Bypass	Mendota Pool	Non-project	4,750
Chowchilla Bypass	Chowchilla Bifurcation Structure	Confluence with Fresno River and Eastside Bypass	Project	5,500
Eastside Bypass	Fresno River	Sand Slough Bypass	Project	10,000-17,000
Sand Slough Bypass	Sand Slough Control Structure	Eastside Bypass	Project	3,000

Notes:
[a] Project levees are those levees constructed to Federal standards as part of a Federal flood control project, in this case, the Lower San Joaquin River Flood Control Project, and non-project levees are those constructed by individual landowners to protect site-specific properties.
[b] Design capacity is defined by the Corps as the amount of water that can pass through reaches of the San Joaquin River and Chowchilla Bypass with a levee freeboard of 3 feet.
Key:
cfs = cubic feet per second

Fresno Slough and the Kings River

Fresno Slough connects the Kings River to the San Joaquin River through the James Bypass. The James Bypass is a leveed channel beginning in the lower Kings River basin and runs northwest to Fresno Slough. The Fresno Slough delivers water to the south from Mendota Pool during irrigation season, and delivers water to the Mendota Pool and San Joaquin River from the Kings River when the Kings River is flooding. Due to this flood inflow, Kings River system operations influence operations on the San Joaquin River at Chowchilla Bifurcation Structure, Mendota Pool, and downstream.

Levees

There are two classes of levees and dikes along the San Joaquin River near Reach 2B: (1) those associated with the Lower San Joaquin River Flood Control Project (project levees), and (2) those constructed by individual landowners to protect site-specific properties, and thus not associated with the Lower San Joaquin River Flood Control Project (non-project levees). There are only non-project levees in Reach 2B; however, project levees exist along the lower portion of Reach 2A and along the entire length of the Chowchilla Bypass.

The San Joaquin River Flood Control Project consists of a parallel conveyance system: (1) a leveed bypass system on the east side of the San Joaquin Valley, and (2) a leveed flow conveyance system in the San Joaquin River. The main stem of the San Joaquin River levee system is composed of approximately 192 miles of project levees and various non-project levees located upstream from the Merced River confluence. Project levees are levees constructed as part of the San Joaquin River Flood Control Project by the Corps, and occur in Reach 2A downstream from Gravelly Ford and extend downstream to the Chowchilla Bifurcation Structure. There are no project levees in Reach 2B. Information on dimensions of estimated channel capacities for locally constructed levees is difficult to obtain and, in some cases, is currently unavailable.

Figure 12-1 shows the levee flood protection zones for the San Joaquin River. Under California Water Code section 9110, subdivision (b), "Levee Flood Protection Zone" means the area, as determined by the CVFPB or DWR that is protected by a project levee. DWR delineated the levee flood protection zones by estimating the maximum area that may be flooded and where flood levels could exceed 3 feet deep if a project levee fails with flows at maximum capacity that may reasonably be conveyed. Reach 2B is not protected by project levees. However, the levee flood protection zone map shown in Figure 12-1 indicates that the entire Project area is subject to inundation with some areas subject to flooding greater than 3 feet if a levee was to fail.

12.1.3 Flood Management Operations and Conditions

The following sections contain information about flood management operations in the Project area and vicinity.

San Joaquin River

The 8,000 cfs objective flow from Friant Dam is generally considered to be a safe carrying capacity, though some flood damages to adjacent land developments can occur when objective flows are passed. These damages can occur because of levee under-seepage and through-seepage, and backwater effects on local storm drainage systems. Design capacity is defined by the Corps as the amount of water that can pass through reaches of the San Joaquin River with a levee freeboard of 3 feet. Design capacity was intended to provide protection against a 50-year storm (McBain and Trush 2002). The intended design capacity of Reach 2B is 2,500 cfs with 3-foot freeboard.

In all cases, water from the Kings River system has priority to use available capacity in the San Joaquin River below the Mendota Pool. When flood flows are below channel capacities, the Lower San Joaquin Levee District (LSJLD) has the latitude to best use the design capacities of the Lower San Joaquin River Flood Control Project.

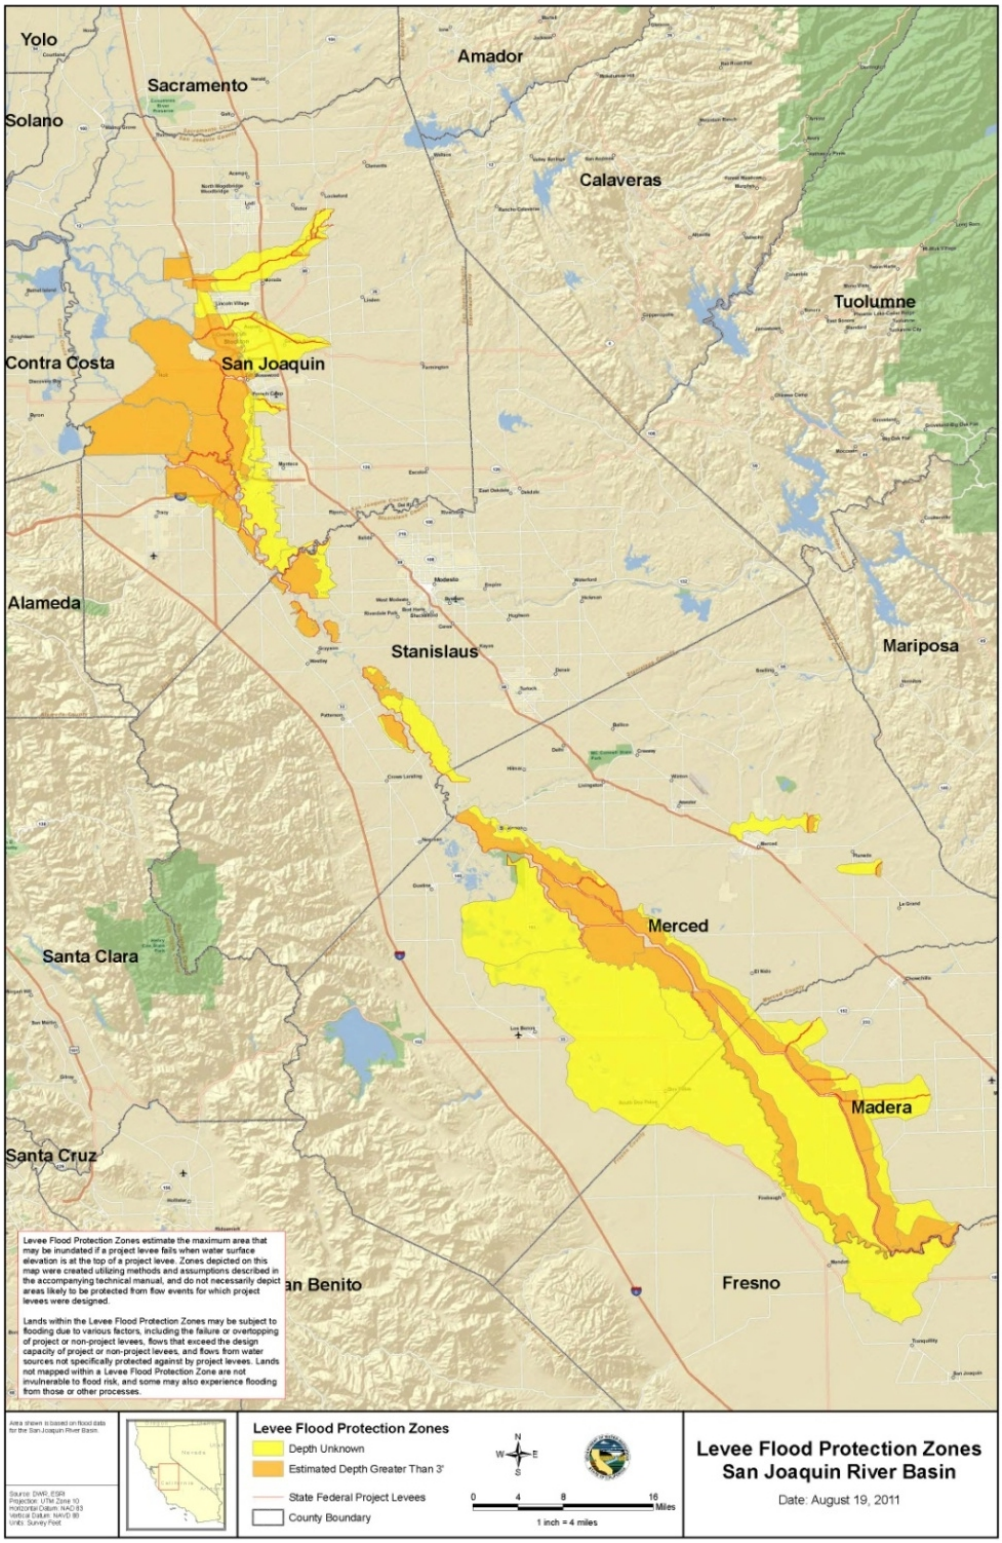

Figure 12-1.
Levee Flood Protection Zones in the San Joaquin River Basin

The following operation and maintenance guidelines describe how the system is operated (Reclamation Board 1969).

- The first increment of flow down the San Joaquin River may be routed through either the San Joaquin River or the Chowchilla Bypass. Up to 2,500 cfs would normally be routed through the San Joaquin River insofar as it does not exceed the capacity of the river when added to the releases from the Kings River. Up to 5,500 cfs would be passed through the Chowchilla Bypass Bifucation Structure. A total flow of 8,000 cfs would normally be divided with 2,500 cfs passing to the river and 5,500 cfs passing to the Chowchilla Bypass.
- Should the flows exceed 8,000 cfs at the control structures or 10,000 cfs at the latitude of Mendota (i.e., the total flow in the San Joaquin River, via Reach 2 and James Bypass/Fresno Slough, and the Chowchilla Bypass at the latitude of Mendota), the LSJLD would operate the control structures at their own discretion with the objective of minimizing damage to the flood control project and protected area.

Major Recent Floods

The following flood event descriptions as reported in Reclamation and DWR (2005) are drawn from the Corps report (Corps 1999). Between 1900 and 1997, the Sacramento River and San Joaquin River basins experienced 13 destructive floods each located in a different portion of the Central Valley. The most recent floods (1983, 1986, 1995, and 1997) caused extensive damage in both the Sacramento River and San Joaquin River basins and raised questions about the adequacy of the current flood management systems and land use in the floodplains. In response to these floods, Congress authorized the Corps in 1997 to undertake a comprehensive study of the flood damage reduction facilities in the Sacramento River and San Joaquin River basins, and to prepare a summary of recent flood events.

Flood of 1955. The flood of 1955 occurred in December, was centered north of Friant Dam, and was more intense in the northern portions of the San Joaquin Valley and in the Sacramento Valley. Before the start of the flood, Millerton Lake was well below flood management space and, as a result, flows on the San Joaquin River were completely controlled by Friant Dam. The peak flow release from Friant Dam for this storm occurred on January 5, 1956, at 7,120 cfs. The flow stayed high for about 6 weeks.

Flood of 1967. Above-normal precipitation that occurred continuously from December 1966 through March 1967 resulted in the flooding of 35,000 acres of the San Joaquin River basin. A record-breaking storm in early December 1966 resulted in very high runoff from the San Joaquin River. The San Joaquin River above Millerton Lake experienced high runoff during early December with a maximum mean daily inflow of 18,450 cfs to the lake. The release from Millerton during this event was about 5,000 cfs and lasted about 1 week. A vast snowmelt from April to July resulted in significant flood damage from flooding in the lower portions of the Fresno and Chowchilla rivers. Nearly all of the flooded areas were cropland, improved pasture, or grazing land. Releases from Millerton climbed to about 8,000 cfs in the first week of April and remained there until the beginning of June. Flow did not return to normal until mid-July.

Flood of 1983. Water year 1983 was one of the wettest on record in California, a result of El Niño weather conditions. Northern and Central California experienced moderate flooding incidents from November through March because of numerous storms. In early May, snow water content in the Sierra Nevada exceeded 230 percent of normal, and the ensuing runoff resulted in approximately four times the average volume for Central Valley streams. In the San Joaquin River basin, levee breaks caused flooding at four locations along the San Joaquin River. Estimated damages exceeded $324 million in the San Joaquin River basin (Corps 1999). Releases from Millerton started to increase in the beginning of November reaching over 12,000 cfs in July, after which they returned to more normal conditions.

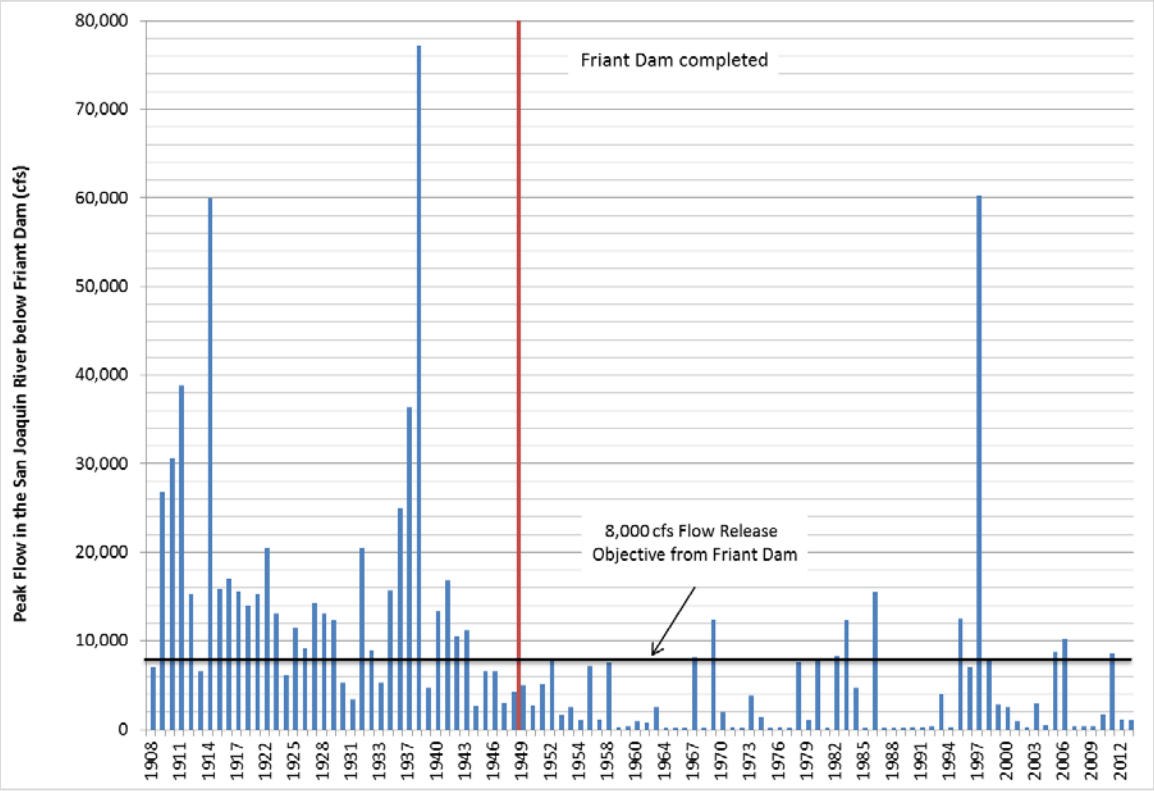
Flood of 1986. Flooding in 1986 resulted from a series of four storms over a 9-day period during February. Rains from the first three storms saturated the ground and produced moderate to heavy runoff before the arrival of the fourth storm. Peak daily inflow to Millerton Lake was about 20,800 cfs. Estimated damages exceeded $15 million in the San Joaquin River basin (Corps 1999). The peak flow from Millerton was 15,500 cfs on February 18. Flows started to return to normal in about mid-April.

Flood of 1995. El Niño conditions in the Pacific forced major storm systems directly into California during much of the winter and early spring of 1995. The largest storm systems hit California in early January and early March. The major brunt of the January storms hit the Sacramento River basin and resulted in small stream flooding primarily because of storm drainage system failures. The March 1995 storms were concentrated on the coastal range, and caused high flows in some of the west side tributaries to the San Joaquin River basin. Peak daily inflow to Millerton Lake was about 23,700 cfs. In total, estimated flood damages in 1995 exceeded $193 million in the San Joaquin River basin (Corps 1999). The peak release from Millerton was 12,500 cfs on March 11, but releases were high from the first week in March to almost August.

Flood of 1997. December 1996 was one of the wettest Decembers on record in the Central Valley. Watersheds in the Sierra Nevada already were saturated by the time three subtropical storms added more than 30 inches of rain in late December 1996 and early January 1997. The third and most severe of these storms lasted from December 31, 1996, through January 2, 1997. Rain in the Sierra Nevada caused record flows that overwhelmed the flood management system in the San Joaquin River basin. Peak daily inflow to Millerton Lake was about 51,800 cfs, with a peak hourly inflow of about 95,000 cfs. Peak daily outflows to the San Joaquin River from Friant Dam were estimated at 37,500 cfs, with a peak hourly outflow of 62,900 cfs. Dozens of levees failed throughout the river system and widespread flooding ensued. Estimated damages exceeded $223 million in the San Joaquin River basin (Corps 1999).

Since 1997 there have been four large flow releases from Friant Dam. In the beginning of June 1998, the flow increased to about 8,000 cfs and remained there for about 3 weeks then slowly decreased to normal levels. In mid-May 2005, the releases from Friant Dam increased to almost 9,000 cfs and remained there for about 2 weeks before dropping to more normal levels. In the beginning of April 2006, the releases increased to 10,000 cfs and remained high for several months decreasing to normal levels in July. In the

beginning of April 2011, the releases increased over 8,000 cfs and remained high for several weeks. Releases peaked again in the end of June and the beginning of July 2011, reaching up to 8,500 cfs. Figure 12-2 shows the peak annual flows below Friant Dam (or at that location before Friant Dam was constructed). Since the dam was constructed in 1949 there have been only 12 events with releases from Friant Dam that exceeded the maximum flow objective of 8,000 cfs. Some of these events lasted many days or months.



Dates before construction of the Dam were collected in the river at the same location.

Figure 12-2.
Peak Annual Flows in the San Joaquin River below Friant Dam

12.1.4 Flood Management Agencies

Federal Emergency Management Agency

Congress established the National Flood Insurance Program to address both the need for flood insurance and the need to lessen the devastating consequences of flooding. FEMA works closely with State and local officials to identify flood hazard areas and flood risks. Floodplain management requirements within high-risk areas, known as Special Flood Hazard Areas, are designed to prevent new development from increasing the flood threat, and to protect new and existing buildings from anticipated flood events. Because the levees in Reach 2B are not authorized flood control levees, the Project area is within a FEMA-designated 100-year flood hazard zone.

U.S. Army Corps of Engineers

The Corps has nationwide responsibility for flood management. In California, flood management on the San Joaquin River system and other rivers is a combination of the Corps, Reclamation, State, and private projects; all operated under the Corps official flood management plans. The Corps has emergency authority to fight any flood to protect life and property and to rehabilitate Federal flood management facilities that are maintained by State and local entities.

Central Valley Flood Protection Board

The CVFPB was established to accomplish the following:

- Control flooding along the Sacramento and San Joaquin rivers and their tributaries, in cooperation with the Corps. This includes working with all permit requests for construction of improvements of any nature within the limits of a Federal project right-of-way; permit requests are referred to the Corps District Engineer for review (in accordance with the provisions of 33 Code of Federal Regulations (CFR) Section 208.10).
- Cooperate with various agencies of the Federal, State, and local governments in establishing, planning, constructing, operating, and maintaining flood control works.
- Maintain the integrity of the existing flood control system and designated floodways through the CVFPB's regulatory authority by issuing permits for encroachments.

California Department of Water Resources

DWR established the Division of Flood Management in November 1977, although flood forecasting and flood operations had been integral functions of the DWR and its preceding agencies for about a century. Today, the functions of statewide flood forecasting, flood operations, and other key flood emergency response activities are the primary missions of the Division of Flood Management Hydrology and Flood Operations Office. Other components of the Division of Flood Management include Flood Projects Office, Flood Maintenance Office, FloodSAFE Program Management Office, and the Central Valley Flood Planning Office.

The Division of Flood Management, among several others, is carrying out the work of DWR's California FloodSAFE Initiative program, which partners with local, regional, State, Tribal, and Federal officials in creating sustainable, integrated flood management and emergency response systems throughout California. DWR is responsible for inspecting Federal project levees and has an obligation to prepare a State Plan of Flood Control and Central Valley Flood Protection Plan. Both plans are required to incorporate any modifications to the flood management system anticipated under the Settlement. In June 2012 the CVFPB adopted the 2012 Central Valley Flood Protection Plan. The plan lays out the goals and objectives to flood protection including ecosystem integration over the following 5 years and includes a vision for long-term flood management over the next 20 to 25 years (DWR 2012).

Lower San Joaquin Levee District

The LSJLD was created in 1955 by a special act of the State Legislature to operate, maintain, and repair levees, bypasses, and other facilities built in connection with the Lower San Joaquin River Flood Control Project. The district encompasses approximately 468 square miles (300,000 acres) in Fresno, Madera, and Merced counties. LSJLD is responsible for operation and maintenance and emergency management of State flood control facilities within the district boundaries including 191 miles of levees, channel bottoms, and flood management facilities. The LSJLD is not responsible for operation and maintenance of privately owned levees. Operations and maintenance activities include vegetation management activities, sediment management and removal activities, cleaning of screens and trash racks on facilities, opening and closing gates and flap gates in the bypass systems, and flood watch. Important facilities maintained by the district include the Chowchilla Bypass, the Eastside Bypass, and the Mariposa Bypass.

12.2 Regulatory Setting

The Federal, State, and regional and local regulatory setting of the Project as it pertains to flood management is described below.

12.2.1 Federal

The Federal regulatory setting describes Executive Order (EO) 11988, and Section 14 of the Rivers and Harbors Act (RHA).

Executive Order 11988 (Flood Hazard Policy)

EO 11988 is a flood hazard policy for all Federal agencies that manage Federal lands, sponsor Federal projects, or provide Federal funds to State or local projects. It requires that all Federal agencies take necessary action to reduce the risk of flood loss; restore and preserve the natural and beneficial values served by floodplains; and minimize the impacts of floods on human safety, health, and welfare. Specifically, EO 11988 dictates that all Federal agencies avoid construction or management practices that would adversely affect floodplains unless that agency finds no practical alternative, and the proposed action has been designed or modified to minimize harm to or within the floodplain.

Rivers and Harbors Act (Section 408)

Section 14 of the RHA (commonly known as Section 408) was approved by the Federal Government on March 3, 1899 (33 United States Code 408). The act provides that the Secretary of the Army, on the recommendation of the Chief of Engineers, may grant permission for the temporary occupation or use of any sea wall, bulkhead, jetty, dike, levee, wharf, pier, or other work built by the United States. Major alterations to a Federal flood control project, including alterations to channels and levees that change the Federal project's authorized geometry or the hydraulic capacity, would require a Corps permit.

12.2.2 State of California

The State regulatory setting describes the Central Valley Flood Protection Act of 2008 and the CVFPB Encroachment Permit.

Central Valley Flood Protection Act of 2008

The Flood Protection Act of 2008 has strengthened flood protection regulations in California. This legislation requires DWR and CVFPB to prepare and adopt a Central Valley Flood Protection Plan. The legislation also establishes certain flood protection requirements for local land use decision-making based on the Central Valley Flood Protection Plan. This law sets new standards for flood protection for the San Joaquin Valley area. It requires an urban level of flood protection necessary to withstand a 1 in 200 chance of a flood event occurring in any given year (200-year flood) for areas developed or planned to have a population of at least 10,000. Under the Central Valley Flood Protection Plan, the State is also considering structural and nonstructural options for rural-agricultural and small communities for protection from a 100-year (1% annual chance) flood.

Central Valley Flood Protection Board Encroachment Permit

Under Title 23 of the California Code of Regulations, the CVFPB issues encroachment permits to maintain the integrity and safety of flood control project levees and floodways that were constructed according to flood control plans adopted by CVFPB or the California Legislature. The CVFPB has jurisdiction over the levee section, the waterward area between project levees, a 10-foot-wide strip adjacent to the landward levee toe, within 30 feet of the top of the banks of unleveed project channels, and within designated floodways adopted by the CVFPB. Activities outside of these limits that could adversely affect the flood control project also fall under the jurisdiction of the CVFPB. In accordance with the provisions of Title 33, CFR Section 208.10, all permit requests for construction of improvements of any nature within the limits of a Federal project right-of-way would be referred to the Corps District Engineer for review.

Project-level actions will require work along the San Joaquin River in areas that may be subject to Title 23 because the river is managed for flood control and thus contains features subject to the jurisdiction of CVFPB. The San Joaquin River is a regulated stream and the proposed action could have an effect on the flood control functions of project levees just east and north of the Chowchilla Bifurcation Structure or downstream project levees. Project proponents will secure encroachment permits, as needed, to satisfy Title 23 before performing any work along relevant reaches of the San Joaquin River that contain flood control features subject to CVFPB jurisdiction.

12.2.3 Regional and Local

Local plans and policies include those designated in county general plans.

Fresno County General Plan

The Fresno County General Plan Policy Document (Fresno County 2000) outlines several policies for flood management.

- Policy HS-C.2 requires that the design and location of dams and levees be in accordance with applicable design standards and specifications and accepted design and construction practices.
- Policy HS-C.6 indicates that the County shall promote flood control measures that maintain natural conditions within the 100-year floodplain of rivers and streams

and, to the extent possible, combine flood control, recreation, water quality, and open space functions.

- Policy HS-C.7 indicates that the County shall continue to participate in the Federal Flood Insurance Program by ensuring compliance with applicable requirements.
- Policy HC-C.10 required that placement of structures and/or floodproofing be done in a manner that will not cause floodwaters to be diverted onto adjacent property, increase flood hazards to other property, or otherwise adversely affect other property.

Madera County General Plan

The Madera County General Plan Policy Document (Madera County 1995) outlines several policies for flood management.

- Policy 6.B.1 requires flood-proofing of structures in areas subject to flooding.
- Policy 6.B.3 restricts uses in designated floodways to those that are tolerant of occasional flooding and do not restrict or alter flow of flood waters.
- Policy 6.B.4 requires that development within areas subject to 100-year floods be designed and constructed in a manner that will not cause floodwaters to be diverted onto adjacent property or increase flood hazards to other areas.

12.3 Environmental Consequences and Mitigation Measures

12.3.1 Impact Assessment Methodology

This section describes the impact assessment methodology for hydrology – flood management resources in the Project area. Assessment included the application of quantitative modeling results and qualitative assessments. The assessment includes review of hydraulic modeling results performed using HEC-RAS and SRH-1D models. These models were used to forecast stages and channel and floodplain velocities for the Project alternatives. The evaluation of flood management impacts considers how proposed changes associated with Project alternatives would affect flooding in Reach 2B and the Restoration Area.

12.3.2 Significance Criteria

The thresholds of significance for impacts are based on the Environmental Checklist Form in Appendix G of the California Environmental Quality Act (CEQA) Guidelines, as amended. These thresholds also encompass the factors taken into account under the National Environmental Policy Act (NEPA) to determine the significance of an action in terms of its context and the intensity of its effects. Impacts to flood management resulting from the Project would be significant if they would cause any of the following:

- Expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure or a levee or dam, including:

  - Increase risk of levee failure due to underseepage, through-seepage, or associated landside slope stability mechanisms (this is described in Chapter 13.0, “Hydrology–Groundwater”).
  - Increase risk of levee failure due to erosion or associated landside slope stability mechanisms.
- Substantially reduce opportunities for levee and flood system facilities inspection and maintenance.
- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.
- Place within a 100-year flood hazard area structures that would impede or redirect flood flows.
- Place housing within a 100-year flood hazard area, as mapped on a Federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map.

Significance standards are relative to both existing conditions (2009) and future conditions (2035) unless stated otherwise.

12.3.3 Impacts and Mitigation Measures

This section provides a project-level evaluation of direct and indirect effects of the Project Alternatives on flood management. It includes analyses of potential effects relative to No-Action conditions in accordance with NEPA and potential impacts compared to existing conditions to meet CEQA requirements. The analysis is organized by project alternative with specific impact topics numbered sequentially under each alternative. With respect to flood management, the environmental impact issues and concerns are:

1. Expose People or Structures to a Significant Risk of Loss, Injury, or Death Involving Flooding.
2. Substantially Reduce Opportunities for Levee and Flood System Facilities Inspection and Maintenance.
3. Substantially Alter Existing Drainage Patterns or Substantially Increase the Rate or Amount of Surface Runoff in a Manner Which Would Result in Flooding On- or Off-Site.
4. Placement of Structures Within a 100-Year Flood Hazard Area that Would Adversely Impede or Redirect Flood Flows.

Other flood-related issues covered in the Program Environmental Impact Statement/Report (PEIS/R) are not covered here because they are programmatic in nature and/or are not relevant to the Project area. The Project does not involve the construction or placement of any housing within a 100-year flood hazard zone. Therefore, this impact is not discussed further.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. However, other proposed actions under the San Joaquin River Restoration Program (SJRRP) would be implemented, including habitat restoration, augmentation of river flows, and reintroduction of salmon. Without the Project in Reach 2B, however, these activities would not achieve the Settlement goals. This section describes the impacts of the No-Action alternative. The analysis is a comparison to existing conditions, and no mitigation is required for No-Action.

Impact FLD-1 (No-Action Alternative*): Expose People or Structures to a Significant Risk of Loss, Injury, or Death Involving Flooding.* Under the No-Action Alternative, the Project would not be implemented, improvements in Reach 2B flood control structures or levees would not occur, and Project areas protected by local levees would remain within the FEMA-designated 100-year flood hazard area. Under existing conditions, the effective flood capacity of Reach 2B is less than the design capacity of 2,500 cfs, which implies that the channel capacity of Reach 2B has been reduced since construction of the existing levees. Reach 2B can functionally pass about 1,600 cfs of San Joaquin River flood flows with the boards out at Mendota Dam, and because of this, San Joaquin River flood flows that may otherwise have been routed through Reach 2B are instead routed through the Chowchilla Bypass. Therefore, the flood system is not operating as envisioned in the flood manual, potentially causing more flood damage to the system and adjacent landowners. This trend of decreasing channel capacity may continue under the No-Action Alternative. This impact is **potentially significant**. No mitigation is required for No-Action.

Impact FLD-2 (No-Action Alternative): *Substantially Reduce Opportunities for Levee and Flood System Facilities Inspection and Maintenance.* Under the No-Action Alternative, the Project would not be implemented and there would be no interruptions to flood system facility inspections and maintenance in Reach 2B. Restoration Flows could cause an increase in sediment deposition above the Chowchilla Bypass control structures requiring additional maintenance activities at this location. This is only one of several control structures maintained in the flood control system and increases in maintenance activities at this location are expected to be minor compared to maintenance requirements for the overall flood control system. This impact would be **less than significant**.

Impact FLD-3 (No-Action Alternative): *Substantially Alter Existing Drainage Patterns or Substantially Increase the Rate or Amount of Surface Runoff in a Manner Which Would Result in Flooding On- or Off-Site.* Under the No-Action Alternative, existing levees and floodplain width would be maintained. There would not be a change to existing drainage patterns that would affect the rate of surface water runoff or infiltration. There would be **no impact**.

Impact FLD-4 (No-Action Alternative): *Placement of Structures Within a 100-Year Flood Hazard Area that Would Adversely Impede or Redirect Flood Flows.* Under the No-Action Alternative, the Project would not be implemented and no additional Project structures would be placed within the 100-year flood hazard area. No actions would be

undertaken that would cause impacts under the No-Action Alternative. There would be **no impact.**

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

Alternative A would include construction of Project facilities, including a Compact Bypass channel, a new levee system encompassing the river channel with a narrow floodplain, and the South Canal. Other key features include construction of the Mendota Pool Dike (separating the San Joaquin River and Mendota Pool), a fish barrier below Mendota Dam, and the South Canal bifurcation structure with fish passage facility and fish screen, modification of the San Mateo Avenue crossing, and the removal of the San Joaquin River control structure at the Chowchilla Bifurcation Structure. Construction activity is expected to occur intermittently over an approximate 132-month timeframe.

Impact FLD-1 (Alternative A*): Expose People or Structures to a Significant Risk of Loss, Injury, or Death Involving Flooding.* The documented existing design capacity of Reach 2B is about 2,500 cfs. Compared to the No-Action Alternative, Alternative A would increase the capacity of Reach 2B to 4,500 cfs with 3 feet of freeboard. This increase in conveyance capacity in Reach 2B provides flood management agencies additional flexibility in how flood flows are managed in the lower San Joaquin River system.

The existing design capacity of Reach 3 is 4,500 cfs. Reach 3 can receive flood flow from the Kings River system through the James Bypass and Fresno Slough or can receive flood flow from the San Joaquin River system through Reach 2B. According to flood management guidelines, water from the Kings River system has priority to use available capacity in the San Joaquin River below Mendota Pool. If 4,500 cfs of flow is conveyed through Fresno Slough, there would be no flood flows conveyed through Reach 2B because there would be no additional capacity in Reach 3. If there is a reduced need for flood flow conveyance through Fresno Slough, Reach 2B is used to convey flood flows. If there is no need to convey flood flows from Fresno Slough, up to 4,500 cfs of flood flows could be conveyed through Reach 2B under Alternative A. This would reduce the amount of flow routed through Chowchilla Bypass, potentially reducing flood damage to the system and adjacent landowners in downstream areas.

Modifications to existing Federal flood control features or flood control operations in the Project area would require approval by the Corps and/or the CVFPB. Modifications to the Chowchilla Bifurcation Structure would not be allowed to affect flood control operations or the LSJLD's ability to route flood flows. However, the LSJLD may choose to use the additional capacity in Reach 2B to carry flood flows.

Flood management agencies have ultimate discretion in directing flood flows. If flood management guidelines are revised subsequent to implementation of the Project, there is a potential that flood flows through Reach 2B could have priority over flood flows from Fresno Slough. However, this is unlikely to occur because overall flood flow conveyance in the system would not be optimized. (If flood flow through Reach 2B was prioritized over Fresno Slough flows, Chowchilla Bypass would have 2,000 cfs of additional flood conveyance capacity.)

The increase in Reach 2B capacity would reduce the risk of flooding in Reach 2B, a beneficial effect for Reach 2B. The Project would build new levees to Corps standards, which would also be a beneficial effect associated with flood management. Under this alternative, the chance of a levee failure in Reach 2B during a large storm event would decrease. Although not observed during recent large flood events, a levee failure in Reach 2B would reduce potential levee failure in reaches downstream of Reach 2B. To the extent that this could occur, reducing the probability of Reach 2B levees failing in the future could increase the probability of downstream levee failure and flooding. However, the likelihood of this happening is low and downstream interests cannot claim flood protection benefits by relying on failure of upstream facilities, nor can they claim they are harmed if the upstream failure does not occur.

The mechanism for increased probability of levee failure would be from an increased frequency of large flows in downstream reaches. Without the Project, only flows up to 2,500 cfs from Reach 2A or flows up to 4,500 cfs from Fresno Slough could be directed through Reach 2B. However, under Alternative A, up to 4,500 cfs of flood or Restoration Flows could be routed from Reach 2A into Reach 3. Therefore, under Alternative A, flows greater than 2,500 cfs but within the Reach 3 capacity could occur more frequently. Potential levee damage from the increased frequency of larger flows would primarily be from erosion, and Program monitoring and maintenance efforts would repair erosion on a regular basis to lessen the likelihood of this leading to levee failures in the Program Restoration Area downstream of Reach 2B.

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). To evaluate the potential for redirected flood risk, flows in Reach 3 with and without the restoration project (inclusive of both Program and Project elements) were estimated for the period from October 1921 through September 30, 2003, using data from the San Joaquin River Restoration Daily Flow Model developed in RiverWare (Reclamation 2012). These data were used to calculate the daily average flow duration and annual maximum flows from Reach 2B to Reach 3. The flow duration curve is a flow exceedance probability curve (Figure 12-3), which shows the percentage of time that the stream flow is likely to equal or exceed a flow value of interest. For example, in Figure 12-3, a flow of 100 cfs from Reach 2B to Reach 3 is exceeded 80 percent of the time under existing conditions and 98 percent of the time under Restoration Flow conditions. In other words, under Restoration Flows, flow from Reach 2B to Reach 3 will be equal to or greater than 100 cfs, 98 percent of the time. A flow of 4,500 cfs (the current capacity of Reach 3) is exceeded less than 0.5 percent of the time under existing conditions. This would increase to about 2.5 percent of the time under Restoration Flows.

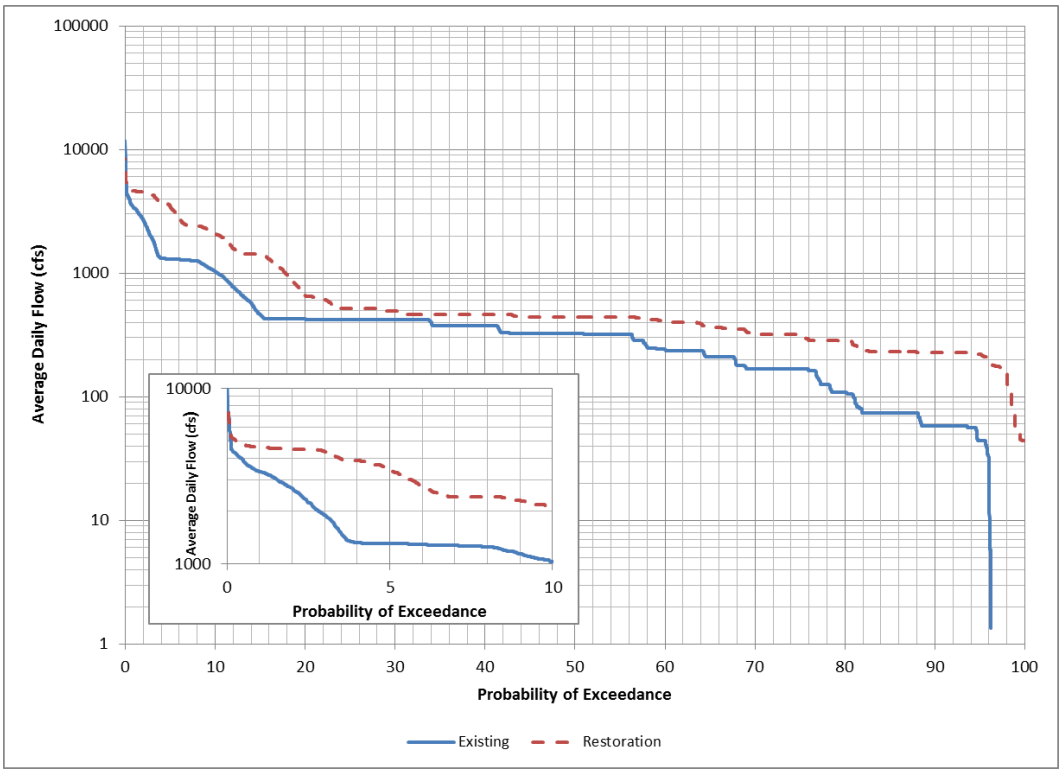


Figure 12-3.
Flow Duration Curve for Flows from Reach 2B

Annual maximum flow is the maximum flow that occurs within any year. It is the flow typically used for the design of levees and other flood control facilities. Though the maximum instantaneous flow rather than the daily average flow is usually used for design on large rivers, such as the San Joaquin River, the two are typically similar. Figure 12-4 shows the flood frequency curve for Reach 3 with and without Restoration Flows. With Restoration Flows, the size of smaller events (less than a 2 percent annual exceedance probability or 50-year event) would increase but for larger, less frequent, flood events the flow would decrease. For example, the 5-year event (20 percent annual exceedance probability) would increase from a little over 2,000 cfs to over 4,000 cfs with Restoration Flows, but the 1 percent annual exceedance flow (100-year event) would decrease from 9,000 cfs to 7,000 cfs.

Overall, increasing the design capacity of Reach 2B to convey Restoration Flows would have a neutral effect. Because the increase in the frequency of smaller, low-risk events would be offset, or partially offset, by a decrease in larger, high-risk events and because Program monitoring and maintenance efforts would repair levee erosion from Restoration Flows, impacts of Alternative A would be **less than significant**.

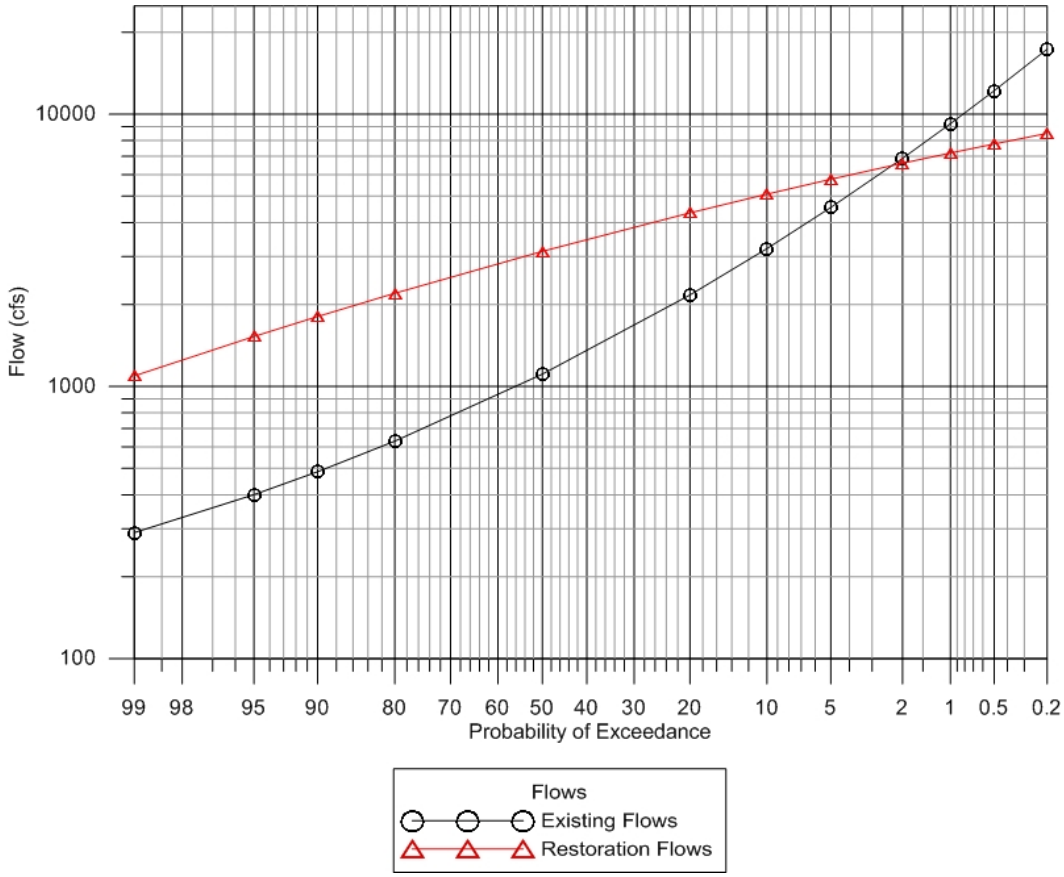

Figure 12-4.
Flood Frequency Curve for Flows from Reach 2B

Impact FLD-2 (Alternative A): *Substantially Reduce Opportunities for Levee and Flood System Facilities Inspection and Maintenance.* LSJLD is responsible for operation and maintenance and emergency management of State flood control facilities within the Project vicinity including maintenance of levees, channel bottoms, and flood management facilities. Operations and maintenance activities include vegetation management activities, sediment management and removal activities, cleaning of screens and trash racks on facilities, opening and closing gates and flap gates in the bypass systems, and flood watch. Important facilities maintained by the district include the Chowchilla Bypass, the Eastside Bypass, and the Mariposa Bypass. The LSJLD is not responsible for operation and maintenance of privately owned levees.

Compared to the No-Action Alternative, construction activities may temporarily limit access to levees and facilities for maintenance and inspection staff. However, construction activities would not completely impede inspection and maintenance activities; minor coordination of such activities would be required. New levees that are constructed would be accessible. Therefore, potential short-term effects would be negligible.

The Project includes long-term operations, maintenance, and monitoring of the proposed facilities and features (see Section 2.2.4). Levees would require access for vegetation management, levee inspections, and levee restoration. Control structures would require access for annual operating maintenance for control gates, lubricating the fittings, greasing and inspecting the motors, replacing parts and equipment, in-channel sediment removal in the structure vicinity, and cleaning the trash rack. Fish passage facilities, fish screens, and fish barriers would also need to be inspected, operated, and maintained. Monitoring activities would require access for physical and nonphysical activities within the Project area, including flow monitoring, groundwater level monitoring, aerial and topographic surveys, vegetation surveys, sediment mobilization monitoring, and monitoring of passage and screening effectiveness. Implementation of these operation, maintenance, and monitoring activities is part of the Project and access would be provided to maintenance and inspection staff. Therefore, long-term access and opportunities for levee and flood system facilities inspection and maintenance would be provided.

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). This impact would be **less than significant**.

Impact FLD-3 (Alternative A): *Substantially Alter Existing Drainage Patterns or Substantially Increase the Rate or Amount of Surface Runoff in a Manner Which Would Result in Flooding On- or Off-Site.* Under Alternative A, setback levees would be constructed to widen the floodplain. The floodplain would also be graded in locations to set it at the elevation desired for restoration. Compared to the No-Action Alternative, these activities would alter local drainage patterns and possibly affect existing drainage outside the mainstem of the river by blocking channels or by redirecting overland flow that otherwise would have drained into the Project footprint. This would potentially cause ponding on the landward side of levees. However, the construction of new levees would include seepage control measures, inspection trenches, maintenance roads, and drainage trenches to direct off-site drainage, as well as the realignment or modification of existing drainage channels (see Section 2.2.4). Surface drainage ditches would only be intended to capture and direct runoff; they are not intended to address groundwater seepage or through-levee seepage. These actions would reduce potential effects to negligible levels.

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative A to the No-Action Alternative). This impact would be **less than significant.**

Impact FLD-4 (Alternative A): *Placement of Structures Within a 100-Year Flood Hazard Area that Would Adversely Impede or Redirect Flood Flows.* The major facilities that would be constructed within the 100-year flood hazard area under Alternative A include the Compact Bypass channel, Mendota Pool Dike, modifications to the San Mateo Avenue crossing, a diversion structure for the South Canal, modifications to the Chowchilla Bifurcation Structure, and fish passage facilities.

Compared to the No-Action Alternative diversion structures and fish passage facilities could create localized backwater and redirection effects. These effects would be considered during Project design. Structures would be designed in general accordance with Reclamation Design Standards No. 3 for water conveyance facilities, fish facilities, and roads and bridges, applicable design codes, and commonly accepted industry standards. Levee design would be based on the Corps *Engineer Manual 1110-2-1913 Design and Construction of Levees* guidelines (Corps 2000a) and *Engineer Manual 1110-2-301 Guidelines for Landscape Planting and Vegetation Management at Floodwalls, Levees, & Embankment Dams* (Corps 2000b).

Localized backwater and redirection effects at Project structures would be considered during design of levee heights. Levees would be designed to maintain 3 feet of freeboard on the levees at 4,500 cfs (see Section 2.2.4). Therefore, flooding effects would be negligible.

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). This impact would be **less than significant.**

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Alternative B would include construction of Project features including a Compact Bypass channel, a new levee system with a wide, consensus-based floodplain encompassing the river channel, and the Compact Bypass Bifurcation Structure with fish passage facility and fish screen. Other key features include construction of a fish passage facility at the San Joaquin River control structure at the Chowchilla Bifurcation Structure, the re-route of Drive 10 ½ (across the Compact Bypass control structure), and removal of the San Mateo Avenue crossing. Construction activity is expected to occur intermittently over an approximate 157-month timeframe.

Impact FLD-1 (Alternative B*): Expose People or Structures to a Significant Risk of Loss, Injury, or Death Involving Flooding.* Refer to Impact FLD-1 (Alternative A). Potential impacts of Alternative B would be the same as potential impacts of Alternative A with the following exception. The Compact Bypass design in Alternative B includes fewer grade control structures than the other alternatives, which would initiate channel bed erosion in Reach 2B to remove sediment that has been deposited in the San Joaquin River arm of Mendota Pool. The channel bed erosion in Reach 2B would result in sediment deposition in the Reach 3 channel for approximately 1 mile downstream of the Compact Bypass (RM 203). The maximum estimated water surface increase resulting from this sedimentation is approximately 0.25 feet. Levee improvements would be extended in the upper portion of Reach 3 to approximately RM 203 to offset this water surface increase if needed to maintain 3 feet of freeboard. This impact would be **less than significant**.

Impact FLD-2 (Alternative B): *Substantially Reduce Opportunities for Levee and Flood System Facilities Inspection and Maintenance.* Refer to Impact FLD-2

(Alternative A). Potential impacts of Alternative B would be the same as potential impacts of Alternative A. This impact would be **less than significant.**

Impact FLD-3 (Alternative B): ***Substantially Alter Existing Drainage Patterns or Substantially Increase the Rate or Amount of Surface Runoff in a Manner Which Would Result in Flooding On- or Off-Site.*** Refer to Impact FLD-3 (Alternative A). Potential impacts of Alternative B would be the same as potential impacts of Alternative A. This impact would be **less than significant.**

Impact FLD-4 (Alternative B): ***Placement of Structures Within a 100-Year Flood Hazard Area that Would Adversely Impede or Redirect Flood Flows.*** Refer to Impact FLD-4 (Alternative A). Potential impacts of Alternative B would be the same as potential impacts of Alternative A, with the following exceptions. The major facilities that would be constructed within the 100-year flood hazard area include the Compact Bypass channel, Compact Bypass Bifurcation Structure, and fish passage facilities, and the San Mateo Avenue crossing would be removed. Localized backwater and redirection effects at Project structures would be considered during design of levee heights. Therefore, flooding effects would be negligible. This impact would be **less than significant.**

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Alternative C would include construction of Project features including Fresno Slough Dam, a new levee system with a narrow floodplain encompassing the river channel, and the Short Canal. Other key features include construction of the Mendota Dam fish passage facility, fish barrier below Fresno Slough Dam, the Short Canal control structure and fish screen, the Chowchilla Bifurcation Structure fish passage facility, modification of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 133-month timeframe.

Impact FLD-1 (Alternative C*): Expose People or Structures to a Significant Risk of Loss, Injury, or Death Involving Flooding.*** Refer to Impact FLD-1 (Alternative A). Potential impacts of Alternative C would be the same as potential impacts of Alternative A. This impact would be **less than significant**.

Impact FLD-2 (Alternative C): ***Substantially Reduce Opportunities for Levee and Flood System Facilities Inspection and Maintenance.*** Refer to Impact FLD-2 (Alternative A). Potential impacts of Alternative C would be the same as potential impacts of Alternative A. This impact would be **less than significant.**

Impact FLD-3 (Alternative C): ***Substantially Alter Existing Drainage Patterns or Substantially Increase the Rate or Amount of Surface Runoff in a Manner Which Would Result in Flooding On- or Off-Site.*** Refer to Impact FLD-3 (Alternative A). Potential impacts of Alternative C would be the same as potential impacts of Alternative A. This impact would be **less than significant.**

Impact FLD-4 (Alternative C): ***Placement of Structures Within a 100-Year Flood Hazard Area that Would Adversely Impede or Redirect Flood Flows.*** Refer to Impact

FLD-4 (Alternative A). Potential impacts of Alternative C would be the same as potential impacts of Alternative A, with the following exceptions. The major facilities that would be constructed within the 100-year flood hazard area include Fresno Slough Dam, Short Canal control structure, fish passage facilities, modification of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. The new dam on Fresno Slough would back up Fresno Slough to a similar level as it is presently backed up by Mendota Dam. The Fresno Slough Dam would have a reinforced concrete spillway. The spillway structure would be comprised of multiple gates, which serve to control the flow of water from the Mendota Pool to the San Joaquin River (see Section 2.2.7). Therefore, flooding effects would be negligible**.** This impact would be **less than significant.**

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Alternative D would include construction of Project features including Fresno Slough Dam, a new levee system with a wide floodplain encompassing the river channel, and the North Canal. Other key features include construction of the Mendota Dam fish passage facility, a fish barrier below Fresno Slough Dam, the North Canal bifurcation structure with fish passage facility and fish screen, removal of the San Joaquin River control structure at the Chowchilla Bifurcation Structure, removal of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 158-month timeframe.

Impact FLD-1 (Alternative D*): Expose People or Structures to a Significant Risk of Loss, Injury, or Death Involving Flooding.* Refer to Impact FLD-1 (Alternative A). Potential impacts of Alternative D would be the same as potential impacts of Alternative A. This impact would be **less than significant.**

Impact FLD-2 (Alternative D): *Substantially Reduce Opportunities for Levee and Flood System Facilities Inspection and Maintenance.* Refer to Impact FLD-2 (Alternative A). Potential impacts of Alternative D would be the same as potential impacts of Alternative A. This impact would be **less than significant.**

Impact FLD-3 (Alternative D): *Substantially Alter Existing Drainage Patterns or Substantially Increase the Rate or Amount of Surface Runoff in a Manner Which Would Result in Flooding On- or Off-Site.* Refer to Impact FLD-3 (Alternative A). Potential impacts of Alternative D would be the same as potential impacts of Alternative A. This impact would be **less than significant.**

Impact FLD-4 (Alternative D): *Placement of Structures Within a 100-Year Flood Hazard Area that Would Adversely Impede or Redirect Flood Flows.* Refer to Impact FLD-4 (Alternative A). Potential impacts of Alternative D would be the same as potential impacts of Alternative A, with the following exceptions. The major facilities that would be constructed within the 100-year flood hazard area include Fresno Slough Dam, the North Canal bifurcation structure, and fish passage facilities. The riverside control structure of the Chowchilla Bifurcation Structure and the San Mateo Avenue crossing would be removed. Portions of the Main Canal and Helm Ditch would be relocated. The new dam on Fresno Slough would back up Fresno Slough to a similar level as it is presently backed up by Mendota Dam. The Fresno Slough Dam would have a reinforced

concrete spillway. The spillway structure would be comprised of multiple gates, which serve to control the flow of water from the Mendota Pool to the San Joaquin River (see Section 2.2.8). Therefore, flooding effects would be negligible**.** This impact would be **less than significant.**

13.0 Hydrology – Groundwater

This section describes the environmental and regulatory settings of groundwater, including the environmental consequences and mitigation, as they pertain to implementation of Project alternatives. Groundwater resources describe the water resources related to water flowing in the subsurface through porous sediments.

13.1 Environmental Setting

The Project area is in Fresno and Madera counties, near the town of Mendota, California, as shown on Figure 1-2 of Chapter 1.0, "Introduction." This area is located above the San Joaquin Valley Groundwater Basin.

13.1.1 Regional Setting

The San Joaquin Valley Groundwater Basin makes up the southern two-thirds of the 400-mile-long, northwest trending asymmetric trough of the Central Valley regional aquifer system in the southern extent of the Great Valley Geomorphic Province. As defined in Bulletin 118, California's Groundwater (California Department of Water Resources [DWR] 2003), the San Joaquin Valley Groundwater Basin is comprised of two hydrologic regions, which are divided by the San Joaquin River near Reach 2B: the San Joaquin River hydrologic region to the north and the Tulare Lake hydrologic region to the south; therefore, the Project area lies within both hydrologic regions.

Groundwater Resources of San Joaquin River Hydrologic Region

The San Joaquin River hydrologic region is heavily groundwater-reliant, with groundwater making up approximately 36 percent of the annual supply for agricultural and urban uses (DWR 2014a). The San Joaquin River hydrologic region consists of surface water basins draining into the San Joaquin River system, from the Cosumnes River basin on the north through the southern boundary of the San Joaquin River watershed. Aquifers in the San Joaquin Valley Groundwater Basin are thick and typically extend to depths of up to 800 feet.

Groundwater in the San Joaquin River hydrologic region historically flowed from the valley flanks to the axis of the valley during predevelopment conditions, then north toward the Delta. In the 1920s, development of a deep-well turbine pump and increased availability of electricity led to expansion of agriculture, and ultimately declining groundwater levels between 1920 and 1950 (DWR 2003). Groundwater pumping and recharge from imported irrigation water have resulted in a change in regional flow patterns. As described in the Program Environmental Impact Statement/Report (PEIS/R) (San Joaquin River Restoration Program [SJRRP] 2011, page 12-4), flow largely occurs from areas of recharge towards areas of lower groundwater levels. Vertical movement of water in the aquifer has been altered in this region as a result of thousands of wells constructed with perforations above and below the confining unit (Corcoran Clay

Member), where present, providing a direct hydraulic connection. This increase in vertical flow may have been partially offset by a decrease in vertical flow resulting from the inelastic compaction of fine-grained materials in the aquifer system, which occurs largely due to deep groundwater pumping. The approximate extent of the Corcoran Clay is illustrated on Figure 13-1.

The aquifer system of the San Joaquin Valley Groundwater Basin is divided into two major aquifers: an unconfined to semiconfined aquifer above the Corcoran Clay, a thick zone of clay deposited as part of the sequence of lacustrine and marsh deposits underlying Tulare Lake, and a confined aquifer beneath the Corcoran Clay. The unconfined to semiconfined aquifer can be divided into three hydrogeologic units based on the source of the sediment: Coast Range alluvium, Sierra Nevada sediments, and flood-basin deposits (see Figures 13-1 and 13-2).

The Coast Range alluvial deposits are derived largely from the erosion of marine rocks from the Coast Range. These deposits are up to 850 feet thick along the western edge of the valley and taper off to the east as they approach the center of the valley floor. The alluvial deposits contain a large proportion of silt and clay, are high in salts, and also contain elevated concentrations of selenium and other trace elements. The Sierra Nevada sediments on the eastern side of the region are derived primarily from granitic rock and consist of predominantly well-sorted micaceous sand. These deposits make up most of the total thickness of sediments along the valley axis and gradually thin to the west until pinching out near the western boundary. The Sierra Nevada sediments are relatively permeable with hydraulic conductivities three times the conductivities of the Coast Range deposits. Flood-basin deposits are relatively thin and were derived in recent time from sediments of the Coast Ranges to the west and from sediments of the Sierra Nevada to the east. These deposits occur along the center of the valley floor and consist primarily of moderately to densely compacted clays ranging between 5 and 35 feet thick.

On a regional scale, the Corcoran Clay divides the groundwater system, ranges from zero to 160 feet thick, and is found between 80 and 400 feet below the land surface. The confined aquifer is overlain by the Corcoran Clay Member of the Tulare Formation and consists of mixed origin sediments.

The semiconfined aquifer system of the San Joaquin Valley has historically been recharged by mountain rain and snowmelt along the valley margins. Recharge has generally occurred by stream seepage, deep percolation of rainfall, and subsurface inflow along basin boundaries. As agricultural practices expanded in the region, recharge was augmented with deep percolation of applied agricultural water and seepage from the distribution systems used to convey this water. Recharge of the lower confined aquifer consists of subsurface inflow from the valley floor and foothill areas to the east of the eastern boundary of the Corcoran Clay Member. Present information indicates that the clay layers, including the Corcoran Clay, are not continuous in some areas, and some seepage from the semiconfined aquifer above does occur through the confining layer.

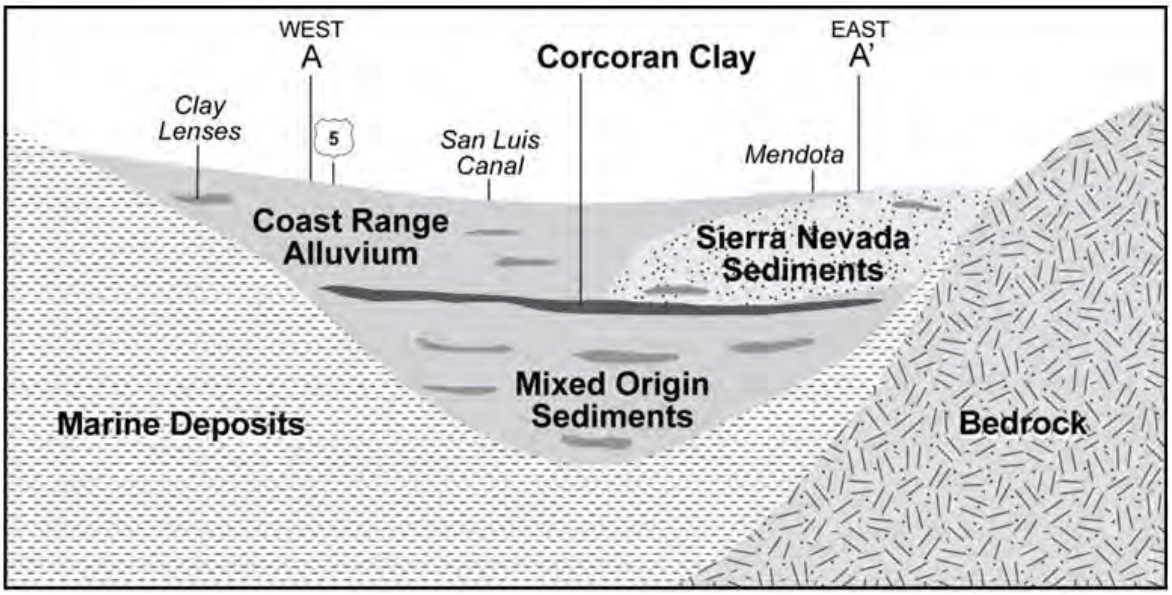
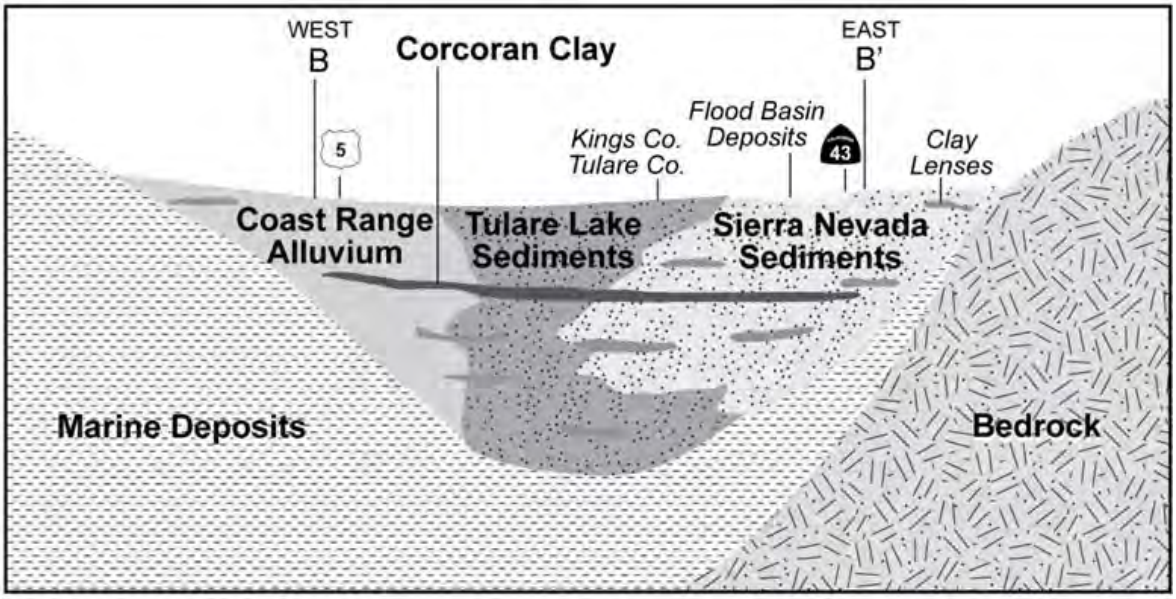
Figure 13-1.
Approximate Boundary of Corcoran Clay and Transect Lines for Hydrogeologic Cross Sections

San Joaquin River Hydrologic Region



Tulare Lake Hydrologic Region



Source: SJRRP 2011

Figure 13-2.
Generalized Hydrogeologic Cross Sections in San Joaquin River and Tulare Lake Hydrologic Regions

The decline in groundwater levels between 1920 and 1950 was as much as 40 to 80 feet in the east side and up to 30 feet in the west side of the San Joaquin River hydrologic region. In 1967, the California Aqueduct replaced groundwater as the primary source of irrigation supply to the area south of Mendota, and consequently, this area became less reliant on groundwater (DWR 2003). However, as illustrated on Figure 13-3,

groundwater pumping continued to increase through time as the acreage of irrigated agriculture continued to increase.

Land subsidence is the lowering of the land-surface elevation due to changes in the subsurface. Four types of land subsidence that occur in the San Joaquin Valley include: aquifer-system compaction due to groundwater level decline, near-surface hydrocompaction, subsidence due to fluid withdrawal from oil and gas fields, and subsidence caused by deep-seated tectonic movements (Sneed et al. 2013). Groundwater level decline along with surface hydrocompaction are the primary causes of land subsidence in the San Joaquin Valley. Maximum land subsidence rates occurred in the 1960s with historic lows in the San Joaquin Valley Groundwater Basin exceeding 30 feet. The southern and western areas of the valley were most affected. Figure 13-4 illustrates land subsidence contours in the San Joaquin River and Tulare Lake hydrologic regions from 1926 to 1970.

Surface water deliveries from the State Water Project and other regional conveyance facilities in the 1970s and 1980s significantly reduced the demand for groundwater for agricultural water use. Although reduced groundwater pumping and imported surface water largely diminished the subsidence problem, subsidence continued in some areas but at a slower rate, due to the time lag involved in the redistribution of pressures in the confined aquifers (DWR 2014a).

Groundwater quality in the San Joaquin Valley Groundwater Basin is variable, but is suitable for most urban and agricultural uses with the exception of some localized areas in the San Joaquin River hydrologic region. The primary constituents of concern include salinity, nitrate, arsenic, total dissolved solids (TDS), boron, chloride, selenium, dibromochloro-propane, and radon. Additional details on groundwater quality are provided in the PEIS/R (SJRRP 2011, page 12-25 to 12-29).

Inadequate drainage and accumulating salts have been persistent problems for irrigated agriculture along the west side and in parts of the east side of the San Joaquin River Hydrologic Region for more than a century. The most extensive drainage problems exist on the west side of the San Joaquin River and Tulare Lake hydrologic regions. The drainage problem developed as a result of imported water from man-made infrastructure, naturally occurring saline soils, and distinctive geology that prevents natural drainage.

Soils on the west side of the San Joaquin River Hydrologic Region are derived from marine sediments are high in salts and trace elements. Irrigation of these soils has mobilized salts and trace elements and facilitated their movement into the shallow groundwater. Much of the irrigation has been with imported water, which has resulted in inadequate drainage, rising groundwater, and increasing soil salinity.

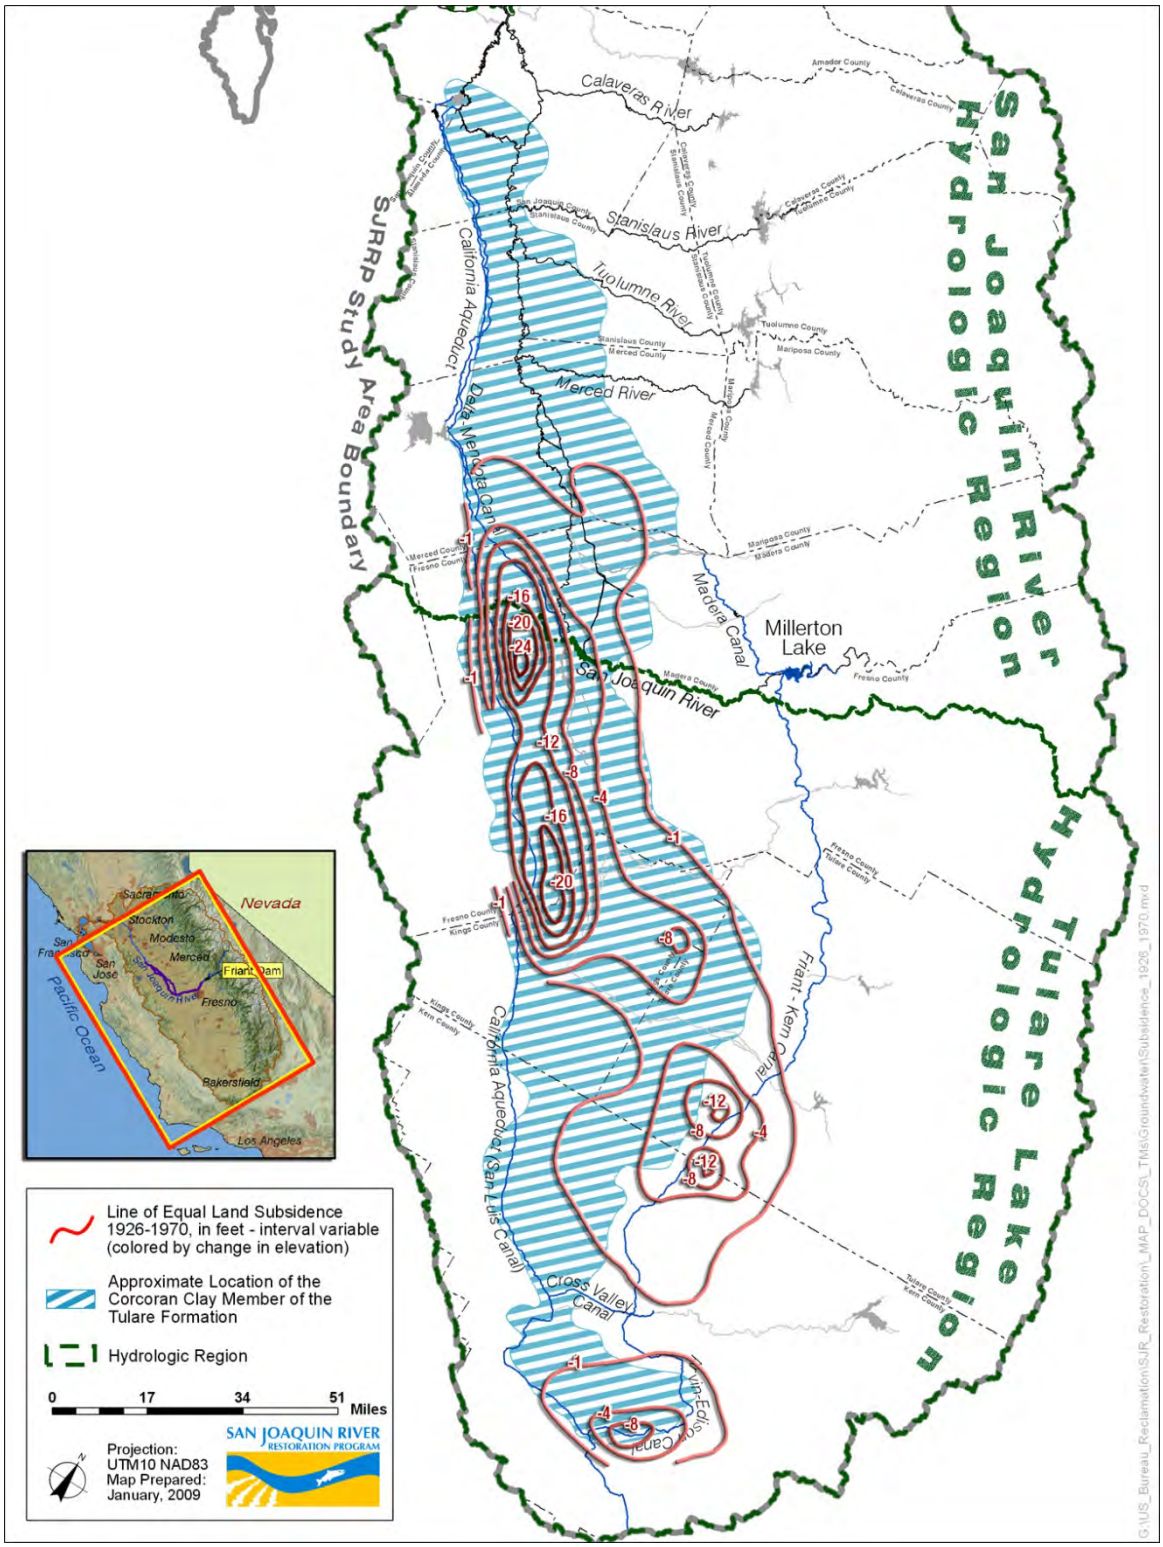
Groundwater Pumping

Figure 13-3.
Historical Groundwater Pumping and Irrigated Agricultural Acreage for San Joaquin River Hydrologic Region



Source: SJRRP 2011

Figure 13-4.
Land Subsidence in the San Joaquin River and Tulare Lake Hydrologic Regions

In some portions of this hydrologic region, natural drainage conditions are poor, and imported irrigation water makes the upper, semiconfined aquifer (shallow groundwater table) even shallower. Therefore, groundwater levels often encroach on the root zone of agricultural crops, and subsurface drainage is often improved with constructed facilities (e.g., interceptor drains) in order to sustain irrigation.

Present problem areas were defined in the San Joaquin Valley Drainage Program (SJVDP) (DWR 2005) as locations where the water table is within 5 feet of the ground surface at any time during the year. Potential problem areas were defined in the SJVDP at locations where the water table is between 5 and 20 feet below the ground surface (DWR 2005). (The term "shallow groundwater" is referred to here as the highest zone of saturation down to a depth of approximately 20 feet below ground surface.)

Seepage and waterlogging of crops along the lower reaches of the San Joaquin River have historically been an issue. High periodic streamflows and local flooding combined with shallow groundwater near the San Joaquin River, and in the vicinity of its confluence with major tributaries, have resulted in seepage-induced waterlogging damage to low lying farmland. During flood-flow events, lateral seepage and structural stability issues with existing levees have been identified. Seepage problems were reported along the Chowchilla Bypass below the bifurcation structure on both sides of the channel in 2006.

Groundwater Resources of Tulare Lake Hydrologic Region

The Tulare Lake hydrologic region is a closed drainage basin at the south end of the San Joaquin Valley, south of the San Joaquin River watershed, encompassing surface water basins draining to the Kern Lake bed, Tulare Lake bed, and Buena Vista Lake bed. The primary aquifer in the San Joaquin Valley Groundwater Basin extends to as deep as 1,000 feet below ground surface in the southern portion of the basin (DWR 2003).

The semiconfined aquifer in the Tulare Lake hydrologic region contains the same hydrogeologic units as the San Joaquin River hydrologic region (Coast Range alluvium, Sierra Nevada sediments, and flood-basin deposits), but the region also contains Tulare Lake sediments in the axis of the valley (see Figure 13-2). The Corcoran Clay occurs at depths between 300 and 900 feet below ground surface in the Tulare Lake hydrologic region. The confined aquifer is overlain by the Corcoran Clay, but consists of the same hydrogeologic units as the unconfined to semiconfined aquifer. The Tulare Lake hydrologic region has semiconfined aquifer conditions to the west above the Corcoran Clay layer, and on the east side of the region where the clay is not present. Tulare Lake sediments present in the axis of the San Joaquin Valley have similar characteristics to flood-basin deposits present in the San Joaquin River hydrologic region (see Figure 13-2).

The semiconfined aquifer in the Tulare Lake hydrologic region is recharged by seepage from streams, canals, infiltration of applied water, and subsurface inflow. Precipitation is a source of recharge to the semiconfined aquifer only in wet years. Seepage from streams and canals is highly variable and depends on annual hydrologic conditions. Some of the water recharged to the semiconfined aquifer seeps through the confining clay layers,

including the Corcoran Clay, which are discontinuous in some areas. Lateral flow from the semiconfined aquifer also recharges the lower confined aquifer.

The Tulare Lake hydrologic region has historically been heavily reliant on groundwater supplies. Agricultural development in the Tulare Lake hydrologic region began in the 1800s, and groundwater has been the primary source of irrigation water. Figure 13-5 illustrates changes in groundwater pumping and irrigated acreage for the Tulare Lake hydrologic region from 1922 to 1980. As described in the PEIS/R (SJRRP 2011, page 12-41), groundwater use in this hydrologic region has historically accounted for 33 percent of the total annual water supply and for 35 percent of all groundwater use in the State. Groundwater use in the hydrologic region represents approximately 10 percent of the State's total agricultural and urban water use.

Similar to the San Joaquin River hydrologic region, the Tulare Lake hydrologic region has been impacted by historical groundwater level decline and resulting land subsidence. Groundwater level decline in central Fresno County between the 1940s and 1980s has been substantial; decreasing approximately 50 to 100 feet (Williamson et al. 1989). Groundwater levels in the lower confined aquifer in the west side of the Tulare Lake hydrologic region declined as much as 400 feet from predevelopment to the 1960s (Williamson et al. 1989). Land subsidence, resulting from groundwater level decline and to a lesser extent from oil and gas withdrawal and near-surface hydrocompaction, is illustrated on Figure 13-4.

As with the San Joaquin River hydrologic region, groundwater quality in the Tulare Lake hydrologic region is variable, but in general, is suitable for most urban and agricultural uses (DWR 2003). The primary constituents of concern are salinity, nitrate, dibromochloropropane, arsenic, TDS, boron, selenium, and radon. Groundwater use for agricultural water supply is limited because of the high TDS concentrations above the Corcoran Clay in the western portion of Fresno and King Counties. Salinity and trace elements in some soil and shallow groundwater on the western side of the Tulare Lake Hydrologic Region are also of concern.

Subsurface drainage problems associated with the west side of the San Joaquin Valley Groundwater Basin extend from north to south in the Tulare Lake Hydrologic Region. The northern boundary of the Tulare Lake Hydrologic Region with the San Joaquin River Hydrologic Region is partially bounded by Reaches 1 and 2 of the San Joaquin River. Seepage problems identified in Reaches 1 and 2 influence local groundwater conditions in the Kings Subbasin in the Tulare Lake Hydrologic Region. (See the "Groundwater Resources of San Joaquin River Hydrologic Region" section above for additional discussion on seepage and waterlogging along the San Joaquin River.)

Conjunctive Use Programs

Conjunctive management or conjunctive use refers to the coordinated and planned use and management of both surface water and groundwater resources to maximize the availability and reliability of water supplies in a region to meet various management objectives. Water is stored in the groundwater basin that is planned to be used later by intentionally recharging the basin when excess water supply is available, for example, during years of above-average surface water supply or through the use of recycled water (DWR 2014b).

Various forms of conjunctive use are practiced throughout California. The form of conjunctive use ranges from incidental conjunctive use benefits to rigorous management programs implemented through detailed operating guidelines. For this discussion, conjunctive use is characterized as incidental conjunctive use, artificial recharge, or active substitution. These three types of conjunctive use can occur individually or may be used in conjunction with one another. Major conjunctive use programs currently in place are highlighted in DWR's *California Water Plan Update* (DWR 2014b) and some of these programs are discussed below; however, this is not a complete summary of all conjunctive use programs currently in operation or planned.

Incidental Conjunctive Use

Incidental conjunctive use occurs when an area relies on surface water when it is available and on groundwater when surface water is not available. Development of surface water storage and delivery projects by U.S. Department of the Interior, Bureau of Reclamation (Reclamation), DWR, and others has been an important factor in allowing water users to reduce groundwater pumping and build up groundwater storage for future use. Management techniques may be used to define the timing and location of surface water deliveries and groundwater pumping to maximize water supply reliability. However, groundwater pumping may increase in years of below-average precipitation and reduced availability of imported surface water supplies.

Artificial Recharge

Conjunctive use programs incorporating artificial recharge methods require a source of surface water (imported or reclaimed) that is not needed for immediate use. The surface water is placed directly into the ground by various means, including spreading ponds and injection. This water is then available for use in dry periods. This is a common practice in many areas of the State, especially in the San Joaquin River and Tulare Lake hydrologic regions.

Active Conjunctive Use Programs

Active conjunctive use programs in the San Joaquin Valley Groundwater Basin, as described in the PEIS/R (SJRRP 2011, page 12-52 to 12-57), include those listed below, the last of which is active in the Project area.

- Semitropic Water Storage District Groundwater Banking Program.
- Kern Water Bank Authority, Kern Water Bank.
- City of Fresno, Leaky Acres Water Recharge Facility.

- Farmington Groundwater Recharge Program.
- Madera Irrigation District Water Supply Enhancement Project.
- Mendota Pool, Ten-Year Exchange Agreements, Proposed Annual Water Exchange, California.

Additional Proposed Groundwater Banking Projects

Additional direct and in-lieu recharge groundwater banks have been proposed in the San Joaquin Valley by Friant Division long-term contractors and non-Friant Division contractors. These proposed projects are listed in the PEIS/R (SJRRP 2011, page 12-56 to 12-57).

13.1.2 Project Setting

Delta-Mendota Subbasin

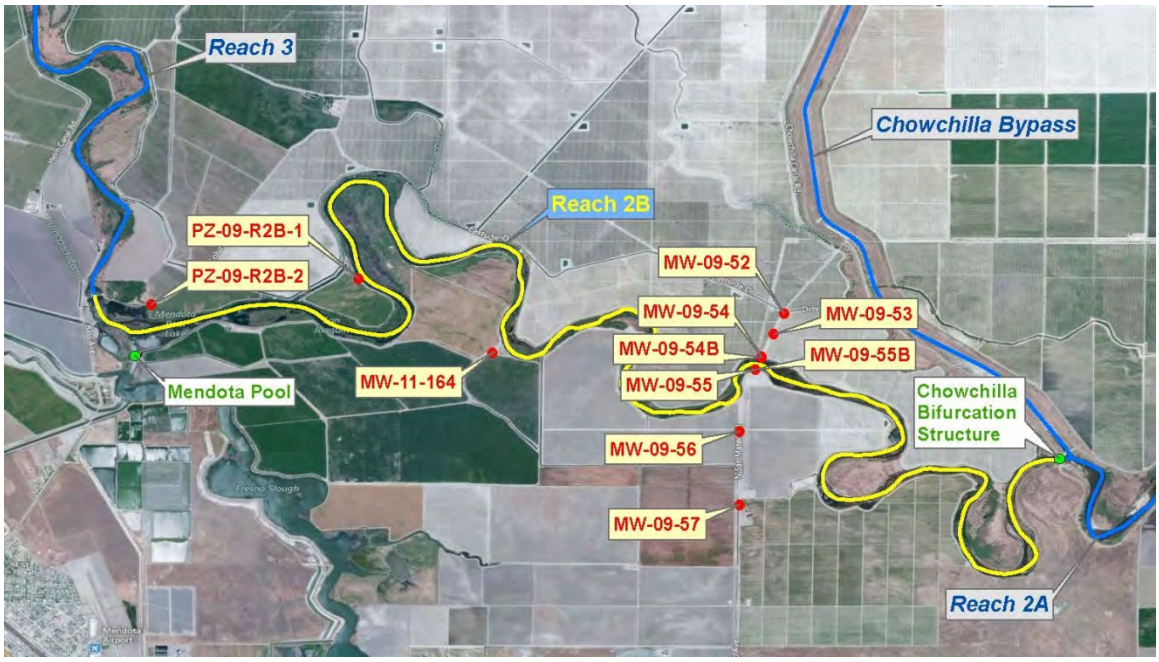
The San Joaquin Valley Groundwater Basin is composed of 16 subbasins: nine of these subbasins are located in the San Joaquin River hydrologic region and seven of these subbasins are located in the Tulare Lake hydrologic region (DWR 2006). The Project area is located within the Delta-Mendota subbasin, which is located within both the San Joaquin River hydrologic region and the Tulare Lake hydrologic region.

Groundwater in the Delta-Mendota subbasin occurs in three water-bearing zones within the Tulare Formation: terrace deposits, alluvium, and flood-basin deposits. The lower section of the Tulare Formation contains confined fresh water. The upper section of the Tulare Formation contains confined, semi-confined, and unconfined water. A shallow zone contains unconfined water approximately 25 feet or less below ground surface. The Corcoran Clay underlies the basin at depths that range from 100 to 500 feet below ground surface and acts as a confining layer.

Land subsidence has occurred in the Delta-Mendota subbasin due to historical groundwater level decline. Total subsidence near Mendota Pool reached nearly 9 feet by 2001, as compared to 1935 levels. Subsidence rates were greatest in the 1950s, with an average rate near Mendota Pool of 4.4 inches per year (in/year) between 1953 and 1957. Subsidence rates near Mendota Pool have been reduced in more recent years, with subsidence rates averaging 0.44 in/year between 1997 and 2001 and 0.04 in/year between 2003 and 2008 (Sneed et al. 2013).

Groundwater Conditions in the Project Area

The Program has collected groundwater data at several locations in the Project area (see Figure 13-6). The majority of these wells monitor shallow groundwater located within the top 20 to 30 feet below ground surface. Station MW-09-54B has real-time data available online at the California Data Exchange Center. At this station, depth to groundwater has ranged from approximately 8 feet to 20 feet below ground surface from February 2010 to July 2013. In Reach 2B, shallower groundwater levels correspond to flood and Interim and Restoration flows, while deeper groundwater corresponds to summer and low flow periods.



Source: SJRRP 2012a

Figure 13-6.
Reach 2B Monitoring Well Atlas

Salt management is one of the most serious long-term groundwater quality issues in the San Joaquin Valley. In this respect, the groundwater in Reach 2B is of relatively high quality. Electrical conductivity, a measure of salinity, at Station MW-09-54B has for the same period ranged from approximately 75 to 325 microsiemens per centimeter (µS/cm). These values are well below the salinity threshold of 1,500 µS/cm established for Reach 2B, as described in the Program's *Seepage Management Plan* (SJRRP 2014). Groundwater quality data for other parameters are limited, as seen in Mathany et al. (2013).

13.2 Regulatory Setting

This section presents applicable Federal, State, and local laws and regulations associated with groundwater resources in the Project area.

13.2.1 Federal

This section presents applicable Federal regulations associated with groundwater resources in the Project area and vicinity.

Clean Water Act

Section 402 of the Clean Water Act created the National Pollutant Discharge Elimination System (NPDES) permit program. This program covers point sources of pollution discharging into a surface water body, including dewatering of shallow groundwater. See Chapter 14.0, "Hydrology – Surface Water Resources and Water Quality," for a discussion of the Clean Water Act.

13.2.2 State of California

This section describes State regulations and policies associated with groundwater resources in the Project area and vicinity.

Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act is California's statutory authority for protecting groundwater quality. See Chapter 14.0, "Hydrology – Surface Water Resources and Water Quality," for a discussion of Porter-Cologne Water Quality Control Act.

Assembly Bill 3030 – Groundwater Management Act

The Groundwater Management Act (Assembly Bill [AB] 3030) is found in sections 10750–10756 of the California Water Code and provides a systematic procedure for an existing local agency to develop a groundwater management plan. AB 3030 gives the local agency the authority to develop a groundwater management plan in groundwater basins defined in DWR Bulletin 118 (DWR 2003) and to raise revenue to pay for facilities to manage the basin (extraction, recharge, conveyance, quality). AB 3030 consists of 12 technical components, but others may be identified in the groundwater management plan. An AB 3030 plan can be developed after a public hearing, and adoption of a resolution of intention to adopt a groundwater management plan. Groundwater management plans have been developed for a number of irrigation districts, counties, cities, and other private districts in the San Joaquin Valley Groundwater Basin, including the San Joaquin River Exchange Contractors Water Authority's *AB 3030 – Groundwater Management Plan* (2008), which covers the Project area.

Other Existing Management Policies

Existing law regarding groundwater is controlled by jurisdictional decisions. The California Water Code provides limited authority over groundwater use by allowing the formation of special districts (or water agencies) through general or special legislation. As reported in the PEIS/R (SJRRP 2011, page 12-50), DWR identifies nine groundwater management agencies formed by such special legislation, none of which are located in the Central Valley area.

Another means of groundwater management exists for surface water agencies that can show that surface water delivered to a given area recharges a local aquifer. Several agencies have used this statutory authority granted by the legislature to levy charges for groundwater extraction. The only agency in the San Joaquin Valley that has exercised this authority is the Rosedale-Rio Bravo Water Storage District in the Tulare Lake hydrologic region, which does not serve the Project area.

13.2.3 Regional and Local

This section provides information about the regional and local regulatory setting, policies, and programs associated with groundwater resources in the Project area and vicinity.

Fresno County General Plan

The Fresno County General Plan Policy Document (Fresno County 2000) outlines several policies for groundwater resources. These policies include the following.

- Policies OS-A.12 through OS-A.17 encourage groundwater recharge, water banking, local groundwater management, and aquifer recharge.
- Policy OSA.25 seeks to protect groundwater resources from contamination and overdraft.
- Policy PF-C.21 provides for new wells that are in close proximity to live streams or water courses.

Madera County General Plan

The Madera County General Plan Policy Document (Madera County 1995) outlines several policies designed to protect groundwater resources. For example, Policies 5.C.1 and 5.C.7 seeks to protect areas of groundwater recharge and to protect groundwater resources from contamination and further overdraft.

13.3 Environmental Consequences and Mitigation Measures

13.3.1 Impact Assessment Methodology

This section describes the impact assessment methodology used to evaluate potential impacts on groundwater resources. The analysis of the Project alternatives is both qualitative and quantitative in nature. Construction-related effects on groundwater were evaluated qualitatively based on review of regional groundwater information and the type of construction activities anticipated. The assessment of areas potentially affected by seepage was quantitative in nature and was based upon a cross-sectional seepage model developed for the Project area by the Program.

The quantitative approach was used to develop estimates of areas vulnerable to seepage and high water table effects associated with potential rises in groundwater levels in the Project area due to the implementation of Project alternatives. The aquifer response to a flow of 4,500 cubic feet per second (cfs) in the San Joaquin River was used to evaluate potential rise in groundwater elevations in the absence of seepage control measures. Results from this modeling represent “worst case” conditions because all Project alternatives would implement seepage control measures as part of the Project design.

The U.S. Geological Survey (USGS) Central Valley Hydrologic Model (CVHM), a valley-wide numerical groundwater flow model (USGS 2009), was used as a starting point for the cross-sectional seepage model. Specifically, CVHM was used as the basis for the development of a series of six, simplified cross-sectional seepage model profiles located at various distances along Reach 2B (Figure 13-7). The CVHM was not directly used because the aerial and vertical grid spacing is too coarse to evaluate groundwater levels immediately adjacent to the river (CVHM was constructed with a lateral grid size of 1 mile by 1 mile and a top layer thickness of 50 feet).

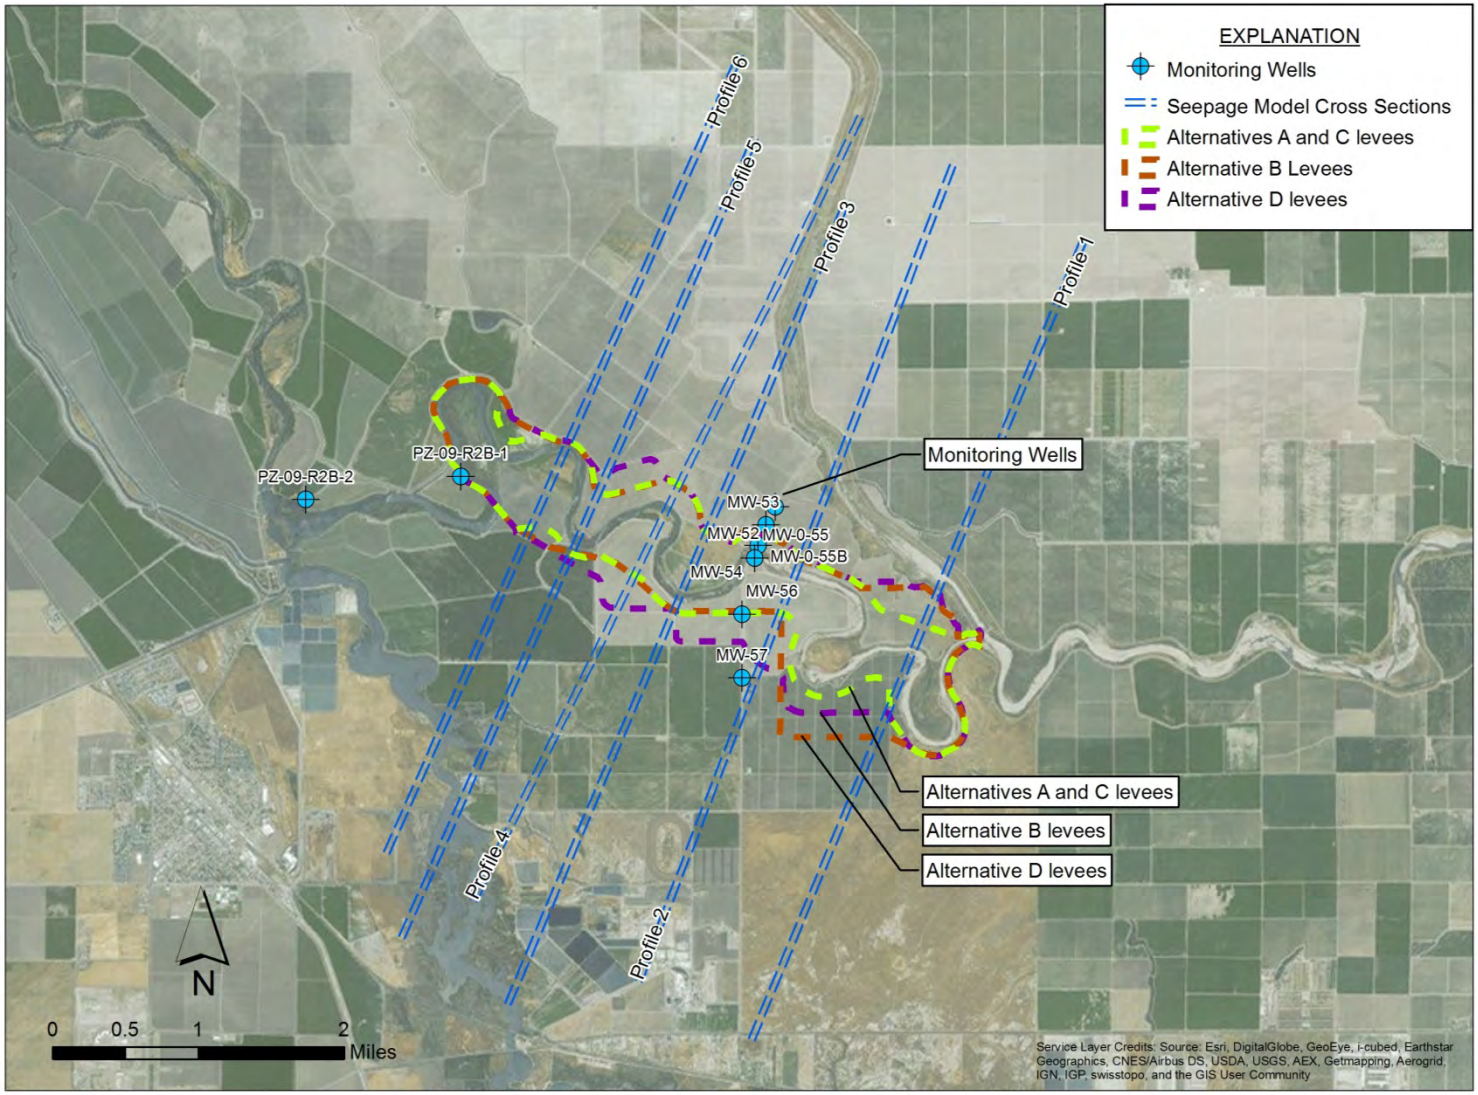


Figure 13-7.
Location of Cross Sectional Seepage Model Cross-Sections

USGS is currently updating CVHM to include the results of a Hydrologic Engineering Center River Analysis System (HEC-RAS) model for the Project area as well as refined grid spacing and layering for the purposes of assessing SJRRP groundwater impacts. The revised CVHM was not available for the Draft Environmental Impact Statement/Report (EIS/R).

Each of the six groundwater model profiles shown in Figure 13-7 is oriented perpendicular to the river channel, and extends approximately 3 miles in each direction away from the river. The profile locations were selected away from river meanders, if possible, in order to minimize numerical errors. Each profile model is composed of six layers, extending from the ground or river surface to the top of the regional confining aquifer unit, the Corcoran Clay. The lateral grid cell size at the river is 10 feet and gradually increases away from the river to a maximum of 400 feet.

The output from the existing HEC-RAS model was used to assign water levels in the river channel at each cross sectional profile. High resolution LiDAR (Light Detection and Ranging) data were incorporated into the model to account for variations in land surface topography. The depths to water simulated by the model[1] were compared with the significance criteria, described below. The distance from the levees at which simulated water level rises exceed the significance criteria were imported into a Geographic Information System (GIS) platform and interpolated spatially along the course of the river to estimate the acreage of land potentially impacted by rising groundwater as a result of Restoration Flows.

13.3.2 Significance Criteria

The thresholds of significance for groundwater impacts are based on the Environmental Checklist Form in Appendix G of the California Environmental Quality Act (CEQA) Guidelines, as amended. These thresholds also encompass factors taken into account under the National Environmental Policy Act (NEPA) to determine the significance of an action in terms of its context and the intensity of its effects. Impacts on groundwater resources would be significant if implementation of an Alternative would cause the following:

- A change in groundwater level resulting in long-term overdraft conditions for the groundwater basins.
- A change in groundwater level adjacent to the San Joaquin River resulting in increased groundwater levels in localized areas already experiencing high groundwater levels.
- A change in groundwater quality resulting in substantially adverse effects to designated beneficial uses of groundwater.

[1] The scenarios simulated by the cross sectional model were based on the initial alternatives evaluation (Project Description Technical Memorandum, Appendix A, SJRRP 2012b). The model scenarios that are comparable to the current alternatives are FP2, which simulates a narrow floodplain, and FP4, which simulates a wide floodplain.

13.3.3 Impacts and Mitigation Measures

This section provides an evaluation of direct and indirect effects of the Project Alternatives on groundwater. It includes analyses of potential effects relative to No-Action conditions in accordance with NEPA and potential impacts compared to existing conditions to meet CEQA requirements. The analysis is organized by Project alternative with specific impact topics numbered sequentially under each alternative. With respect to groundwater, the environmental impact issues and concerns are:

1. Temporary Construction-Related Effects on Groundwater Quality.
2. Long-term Changes in Groundwater Quality.
3. Changes in Groundwater Levels.
4. Changes in Groundwater Recharge.

Other groundwater-related issues covered in the PEIS/R are not covered here because they are programmatic in nature and/or are not relevant to the Project area. Long-term overdraft as a result of Restoration Flows is also not anticipated due to the additional infiltration of river water to the regional aquifer system. Therefore, these issues are not applicable and are not discussed further.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. However, other proposed actions under the SJRRP would be implemented, including habitat restoration in other reaches, augmentation of river flows, and reintroduction of salmon. Without the Project in Reach 2B, however, the proposed actions in other reaches would not achieve the Settlement goals. This section describes the impacts of the No-Action Alternative. The analysis is a comparison to existing conditions.

Impact GRW-1 (No-Action Alternative): ***Temporary Construction-Related Effects on Groundwater Quality.*** Under the No-Action Alternative, the Project would not be implemented and there would be no construction activities in the Project area. As a result, there would be **no impact** to groundwater quality from construction-related effects.

Impact GRW-2 (No-Action Alternative): ***Long-term Changes in Groundwater Quality.*** Under the No-Action Alternative, the quality of shallow groundwater is not anticipated to change substantially. Groundwater quality in the reach is influenced by the quality of the surface water that infiltrates locally. Because Millerton Lake is a source of high quality water with lower salinity than Mendota Pool, infiltration of Restoration Flows would improve the quality of shallow groundwater in the reach. Compared to existing conditions, there would be a **beneficial** effect on groundwater quality over time.

Impact GRW-3 (No-Action Alternative): ***Changes in Groundwater Levels.*** Prior to the start of Interim Flows in October 2009, portions of the Project area historically experienced groundwater seepage to adjacent lands during elevated flood flows. Seepage in Reach 2B has been observed at flows above 1,300 cfs when the Mendota Dam flashboards are in place (RMC 2007). Seepage in Reach 2B caused by high flows can be

reduced by removal of the flashboards and by opening the sluice gates at Mendota Dam in advance of high-flow conditions. This process lowers the water level in the pool during high flow events to reduce seepage impacts to adjacent lands.

Under the No-Action Alternative, flows could continue to affect areas outside of the levees that have historically experienced groundwater seepage. Increases in flow duration or frequency could affect adjacent agricultural lands by saturating soil in the rooting zone, impairing plant growth and survival, or interfering with the ability to use machinery to work soil. However, Program-level seepage management measures would be implemented in the Project area that would minimize impacts to areas near the river channel. Consequently, adverse effects to agricultural lands would be minimized. Compared to existing conditions, seepage-related impacts in the Project area would continue under the No-Action Alternative; however, Program-level seepage management measures would be implemented to minimize seepage-related effects. As a result, there would be a **less-than-significant** impact from changes in groundwater levels.

Impact GRW-4 (No-Action Alternative): ***Changes in Groundwater Recharge.*** Under the No-Action Alternative, Restoration Flows would be conveyed through Reach 2B. The No-Action Alternative would maintain the existing levee alignments and heights and maximum conveyance would continue to be limited to the existing channel capacity. Although the area for potential groundwater recharge would not change compared to existing conditions, flow would occur year-round for most water year types (see Figure 1-10) resulting in groundwater recharge in previously dry sections of the river (i.e., the river channel above the San Joaquin River arm of Mendota Pool). As a result, there would be a **beneficial** effect on groundwater recharge in the Project area.

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

Alternative A would include construction of Project facilities including a Compact Bypass channel, a new levee system encompassing the river channel with a narrow floodplain, and the South Canal. The Reach 2B floodplain would have an average width of approximately 3,000 feet. Other key features include construction of the Mendota Pool Dike (separating the San Joaquin River and Mendota Pool), a fish barrier below Mendota Dam, and the South Canal bifurcation structure with fish passage facility and fish screen, modification of the San Mateo Avenue crossing, and the removal of the San Joaquin River control structure at the Chowchilla Bifurcation Structure. Construction activity is expected to occur intermittently over an approximate 132-month timeframe.

Impact GRW-1 (Alternative A): ***Temporary Construction-Related Effects on Groundwater Quality.*** Construction associated with channel and structural improvements under Alternative A could temporarily influence surface water quality, and could potentially lead to changes in groundwater quality. Compared to the No-Action Alternative, construction activities under Alternative A could discharge waste petroleum products or other construction-related substances that could enter waterways in runoff. In addition, chemicals associated with operating heavy machinery would be used, transported, and stored onsite during construction activities. These substances could be inadvertently introduced into the San Joaquin River through site runoff or onsite spills. Sediment and chemicals could degrade water quality in the San Joaquin River. This

would potentially affect groundwater quality through percolation from the soil surface or surface water interaction with underlying groundwater. Furthermore, the Project could potentially impact groundwater quality through discharges of dewatering effluent if groundwater is encountered during construction.

When comparing Alternative A to existing conditions, impacts to groundwater quality from potential discharges of chemicals through site runoff or onsite spills would be similar to those described above (i.e., the comparison of Alternative A to the No-Action Alternative). These impacts to groundwater quality would be **potentially significant**.

Mitigation Measure GRW-1A (Alternative A): ***Prepare and Implement a Stormwater Pollution Prevention Plan.*** This mitigation measure is the same as Mitigation Measure SWQ-1 (Alternative A), as described in Chapter 14.0, "Hydrology – Surface Water Quality." Construction activities are subject to construction-related stormwater permit requirements of the Federal Clean Water Act's NPDES program. A Stormwater Pollution Prevention Plan (SWPPP) will be prepared that identifies best management practices (BMPs) to prevent or minimize the introduction of contaminants into surface waters. The SWPPP will detail the construction-phase housekeeping measures for control of contaminants, as well as the treatment measures and BMPs to be implemented for control of pollutants once the Project has been constructed. The SWPPP will establish good housekeeping measures such as construction vehicle storage and maintenance, handling procedures for hazardous materials, and waste management best management practices. They include procedural and structural measures to prevent release of wastes and materials used at the site. Implementation of the SWPPP would avoid or reduce runoff pollutants at the construction sites to the "maximum extent practicable."

Implementation Action: The Project proponents and/or construction contractor will prepare and implement an SWPPP consistent with requirements in the Statewide NPDES Construction General Permit. The SWPPP will set forth a best management practice monitoring, maintenance, and reporting schedule and will identify the responsible entities during the construction and post-construction phases. Monitoring will include visual inspections of the best management practices, inspection for non-stormwater discharges, and visual inspection and/or sample collection of stormwater discharges. If monitoring results indicate polluted discharges, a construction site and run-on evaluation will be conducted to determine the source of the pollutant and corrective actions will be implemented immediately if necessary.

Location: Project areas with active construction or used by construction personnel, including access roads, staging and storage areas, borrow sites, within the river channel and on adjacent uplands.

Effectiveness Criteria: Performance tracking will be based on successful compliance with the Statewide NPDES Construction General Permit.

Responsible Agency: Reclamation and the construction contractor.

Monitoring/Reporting Action: At a minimum, annual reports will be submitted to the State Water Resources Control Board via the Storm Water Multiple Application and Report Tracking System.

Timing: The SWPPP will be developed prior to construction and will be implemented during construction.

Mitigation Measure GRW-1B (Alternative A): ***Prepare and Implement a Construction Groundwater Management Plan.*** The Project proponents and/or construction contractor will prepare and implement a Construction Groundwater Management Plan that includes a protocol for sampling and analyzing the quality of dewatering effluent during construction for comparison with existing groundwater. This plan will be consistent with the monitoring and reporting program required by the Statewide NPDES Construction General Permit and/or RWQCB's NPDES Permit for *Dewatering and Other Low Threat Discharges to Surface Waters*, Order No. R5-2013-0074 (General Permit for Low Threat Discharges).[2]

Implementation Action: The Project proponents and/or construction contractor will prepare and implement a Construction Groundwater Management Plan. The plan will include a protocol for sampling and analysis of dewatering effluent during construction and include a description of the sampling methods, locations, and frequency, the constituents monitored, and how the receiving waters will be visually inspected. If monitoring results indicate polluted effluent, a Report of Waste Discharge will be filed with the RWQCB to initiate consultations to obtain a Waste Discharge Order specifying approved treatment methods and disposal options.

Location: Project areas with active dewatering.

Effectiveness Criteria: Performance tracking of this mitigation measure will be based upon successful compliance with the Statewide NPDES Construction General Permit and/or General Permit for Low Threat Discharges.

Responsible Agency: Reclamation and the construction contractor.

Monitoring/Reporting Action: At a minimum, annual reports will be submitted to Reclamation managers summarizing the monitoring data obtained during the previous year(s).

Timing: The Construction Groundwater Management Plan will be developed prior to construction and will be implemented during construction.

Impacts to groundwater quality would be **less than significant** after mitigation.

[2] The General Permit for Low Threat Discharges covers construction dewatering when the discharges do not contain significant quantities of pollutants and they are either 4 months or less in duration or have a daily average discharge flow that does not exceed 0.25 million gallons per day.

Impact GRW-2 (Alternative A): ***Long-term Changes in Groundwater Quality.*** Compared to the No-Action Alternative, implementation of Alternative A would construct new levees set back from the San Joaquin River, expand the floodplain, and increase the conveyance capacity of the reach. Groundwater in the reach is influenced by soil quality and surface water that infiltrates locally. Conversion of previously irrigated agricultural lands into floodplain areas would reduce new sources of nutrients and pesticides that could influence groundwater quality locally.

Alternative A also includes passive riparian habitat restoration and compatible agricultural practices in the floodplain (e.g., annual crops, pasture, or floodplain-compatible permanent crops). Similar to No-Action conditions, where irrigation of agricultural lands would influence the quality of the shallow aquifer, floodplain inundation of agricultural areas would facilitate movement of nutrients and other materials into the shallow aquifer. However, unlike No-Action conditions, nutrient cycling and pollutant uptake following high flow events on the floodplain would be supported by native aquatic, riparian, and floodplain vegetation.

Compared to existing conditions, surface water quality in Reach 2B would primarily be influenced by San Joaquin River flows (instead of other inflows to Mendota Pool) under Alternative A. Because Millerton Lake is a source of high quality water with lower salinity than Mendota Pool, infiltration of river flows could improve the quality of shallow groundwater in Reach 2B. This would be a **beneficial** effect to long-term groundwater quality.

Impact GRW-3 (Alternative A): ***Changes in Groundwater Levels.*** Restoration Flows could cause changes to groundwater levels in Reach 2B in areas adjacent to the San Joaquin River. Drainage problem areas were defined in the SJVDP (DWR 2005) as locations where the water table is within 5 feet of the ground surface. Potential impacts from the Project have been evaluated in relation to similar thresholds: acres of land outside the proposed levee alignments anticipated to have shallow groundwater elevations above 5 and 7 feet below ground surface. These thresholds represent a range of depths where waterlogging of crops and root-zone salinization may affect adjacent land uses. As described in Section 13.3.1, groundwater levels associated with the conveyance capacity of the reach (4,500 cfs) have been simulated and the acreage of land above these thresholds have been quantified in GIS.

Modeling results indicate the potential presence of shallow groundwater levels above the thresholds of 5 and 7 feet below ground surface along the edges of the San Joaquin River levees in the absence of seepage control measures. Based on the model results, the area outside of the levee alignments with simulated depth to groundwater less than 5 feet is 320 acres and an additional 60 acres is simulated to have depth to groundwater between 5 and 7 feet when river flows are at 4,500 cfs. Figure 13-8 shows the potential areas with depths to groundwater less than monitoring thresholds for the narrow floodplain alternatives, which includes Alternative A. The model shows that infiltration and seepage from the river migrates primarily downward to the water table. The mound of groundwater produced from this infiltration and seepage does not extend more than 1,000 feet laterally from the river.

Under Alternative A, newly constructed levees would be set back from the San Joaquin River such that the Reach 2B floodplain would have an average width of approximately 3,000 feet. Although shallow groundwater could potentially be present and effect adjacent land uses, levee design includes implementation of seepage control measures.

Seepage of river water through or under levees is a concern for levee integrity and adjacent land uses. Through-seepage, water that seeps laterally through the levee section, would be addressed through proper levee design and construction (e.g., selection of low porosity materials and proper compaction). Under-seepage, water that seeps laterally by travelling under the levee section, is primarily controlled by the native soils beneath the levee and seepage control measures would be included where native soils do not provide sufficient control. Seepage control measures would be included, as part of the Project, in in areas where under-seepage is likely to affect adjacent land uses. Seepage control measures could include slurry walls, interceptor drains, seepage wells, seepage berms, land acquisition (fee title or seepage easements) and other measures that can be implemented within the Project area (see Section 2.2.4).

In addition to Project design features, seepage management would be implemented during Project operations. Areas of high groundwater would be identified in accordance with the Program's *Seepage Management Plan* (SJRRP 2014). Once identified, the Program's *Seepage Management Plan* would be implemented to identify measures that would be taken to reduce potential impacts. Through these actions, potential adverse effects of an elevated groundwater level, such as waterlogging of crops and mobilizing of salts in the soil profile, would be further avoided or substantially reduced. Seepage impacts to adjacent lands (outside of the floodplain proposed under Alternative A) are likely to be similar to or less than seepage impacts to adjacent lands (outside of the existing levee alignment) under the No-Action Alternative.

Compared to existing conditions, groundwater levels would likely increase in areas outside of the floodplain proposed under Alternative A, however, seepage impacts would be avoided or substantially reduced by implementation of Project design features and seepage management measures. Therefore, impacts would be **less than significant**.

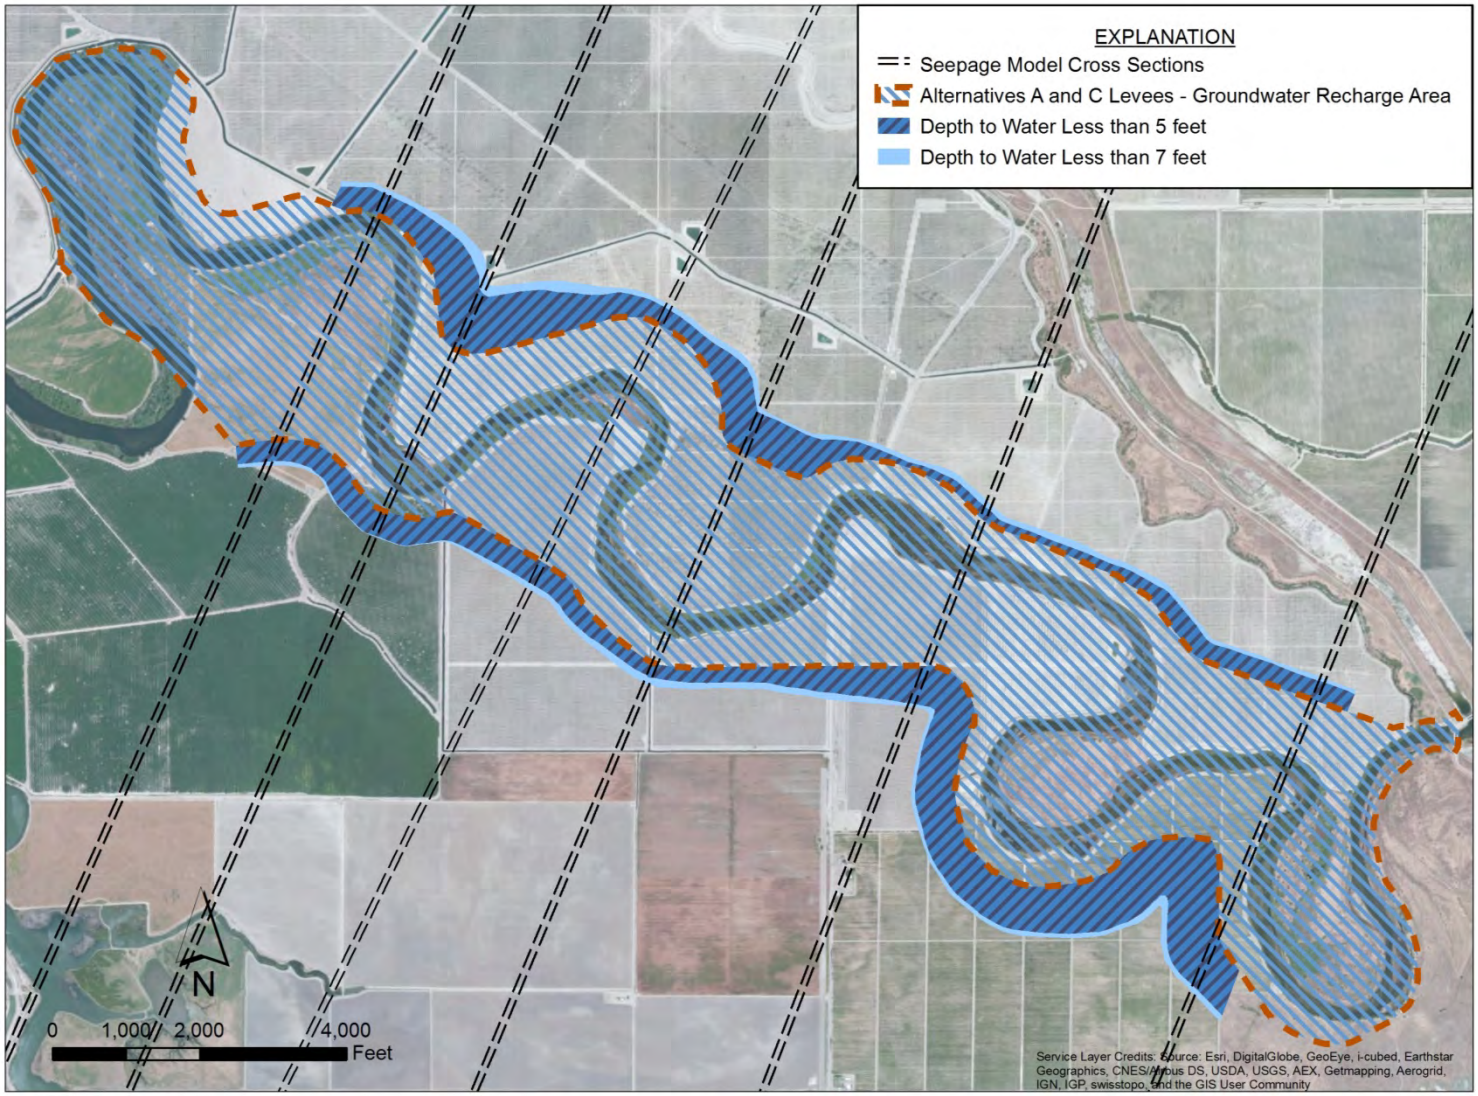

Figure 13-8.
Potential Areas with Depths to Groundwater Less than Monitoring Thresholds – Alternatives A and C

Impact GRW-4 (Alternative A): ***Changes in Groundwater Recharge.*** Compared to the No-Action Alternative, Action Alternatives would construct new levees set back from the San Joaquin River, expand the floodplain, and increase the conveyance capacity of the reach to 4,500 cfs. Under Alternative A the floodplain would have an average width of approximately 3,000 feet. Flow would be conveyed though Reach 2B in the river channel and floodplain providing opportunities for groundwater recharge. Floodplain and channel grading would be used to increase inundation areas during high flow events, remove high areas where flow connectivity would be impeded, and to create floodplain benches adjacent to the river channel to increase the frequency of inundation (see Section 2.2.4). Increasing inundation areas and inundation frequencies would facilitate groundwater recharge in the reach.

Compared to existing conditions, flow would also occur year-round for most water year types (see Figure 1-10) resulting in groundwater recharge in previously dry sections of the river (i.e., in the river channel above the San Joaquin River arm of Mendota Pool). As a result, there would be a **beneficial** effect on groundwater recharge in the Project area.

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Alternative B would include construction of Project features including a Compact Bypass channel, a new levee system with a wide, consensus-based floodplain encompassing the river channel, and the Compact Bypass Bifurcation Structure with fish passage facility and fish screen. Other key features include construction of a fish passage facility at the San Joaquin River control structure at the Chowchilla Bifurcation Structure, the re-route of Drive 10 ½ (across the Compact Bypass control structure), and removal of San Mateo Avenue crossing. Construction activity is expected to occur intermittently over an approximate 157-month timeframe. The Reach 2B floodplain would have an average width of approximately 4,200 feet.

Impact GRW-1 (Alternative B): ***Temporary Construction-Related Effects on Groundwater Quality.*** Construction associated with channel and structural improvements under Alternative B could temporary influence water quality, and could potentially lead to changes in groundwater quality. Refer to Impact GRW-1 (Alternative A). Potential impacts of Alternative B would be the same as potential impacts of Alternative A. These impacts would be **potentially significant**.

Mitigation Measures GRW-1A and GRW-1B (Alternative B): ***Prepare and Implement a Stormwater Pollution Prevention Plan, Prepare and Implement a Construction Groundwater Management Plan.*** Refer to Mitigation Measures GRW-1A and GRW-1B (Alternative A). The same measures would be used here. Impacts would be **less than significant** after mitigation.

Impact GRW-2 (Alternative B): ***Long-term Changes in Groundwater Quality.*** Refer to Impact GRW-2 (Alternative A). Potential effects of Alternative B would be the same as potential effects of Alternative A. Conversion of previously irrigated agricultural lands into floodplain areas would reduce new sources of nutrients and pesticides that could influence groundwater quality locally. These effects would be **beneficial**.

Impact GRW-3 (Alternative B): ***Changes in Groundwater Levels.*** Modeling results indicate the potential presence of shallow groundwater levels above the thresholds of 5- and 7-feet below ground surface along the edges of the San Joaquin River. Based on the model results, the area outside of the levee alignments with simulated depth to water less than 5 feet is 360 acres and an additional 80 acres have simulated depth of 5 to 7 feet below ground surface. Figure 13-9 shows the potential areas with depths to groundwater less than monitoring thresholds for the wide floodplain alternatives, including Alternative B. Similar to Alternative A, the model shows that infiltration and seepage from the river migrates primarily downward to the water table. The mound of groundwater produced from this infiltration and seepage does not extend more than 1,000 feet laterally from the river.

Through levee design features and seepage management measures, as described in Impact GRW-2 (Alternative A), potential adverse effects of an elevated groundwater level, such as waterlogging of crops and mobilizing of salts in the soil profile, would be avoided or substantially reduced in Alternative B. Compared to the No-Action Alternative, seepage impacts to adjacent lands under Alternative B are likely to be similar to or less than seepage impacts to adjacent lands under the No-Action Alternative.

Compared to existing conditions, groundwater levels would likely increase in areas immediately adjacent to San Joaquin River levees, however, seepage impacts would be avoided or substantially reduced by implementation of Project design features and seepage management measures. Therefore, these impacts would be **less than significant**.

Impact GRW-4 (Alternative B): ***Changes in Groundwater Recharge.*** Refer to Impact GRW-4 (Alternative A). Potential effects of Alternative B would be similar to potential effects of Alternative A, with the exception that the floodplain would have an average width of approximately 4,200 feet. Increasing inundation areas and inundation frequencies would facilitate groundwater infiltration causing a **beneficial** effect on groundwater recharge.

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Alternative C would include construction of Project features including Fresno Slough Dam, a new levee system with a narrow floodplain encompassing the river channel, and the Short Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the Short Canal control structure and fish screen, the Chowchilla Bifurcation Structure fish passage facility, modification of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 133-month timeframe. The Reach 2B floodplain would have an average width of approximately 3,000 feet.

Impact GRW-1 (Alternative C): ***Temporary Construction-Related Effects on Groundwater Quality.*** Construction associated with channel and structural improvements under Alternative C could temporary influence water quality, and could potentially lead to changes in groundwater quality. Refer to GRW-1 (Alternative A). Potential impacts of Alternative C would be the same as potential impacts of Alternative A. These impacts would be **potentially significant**.

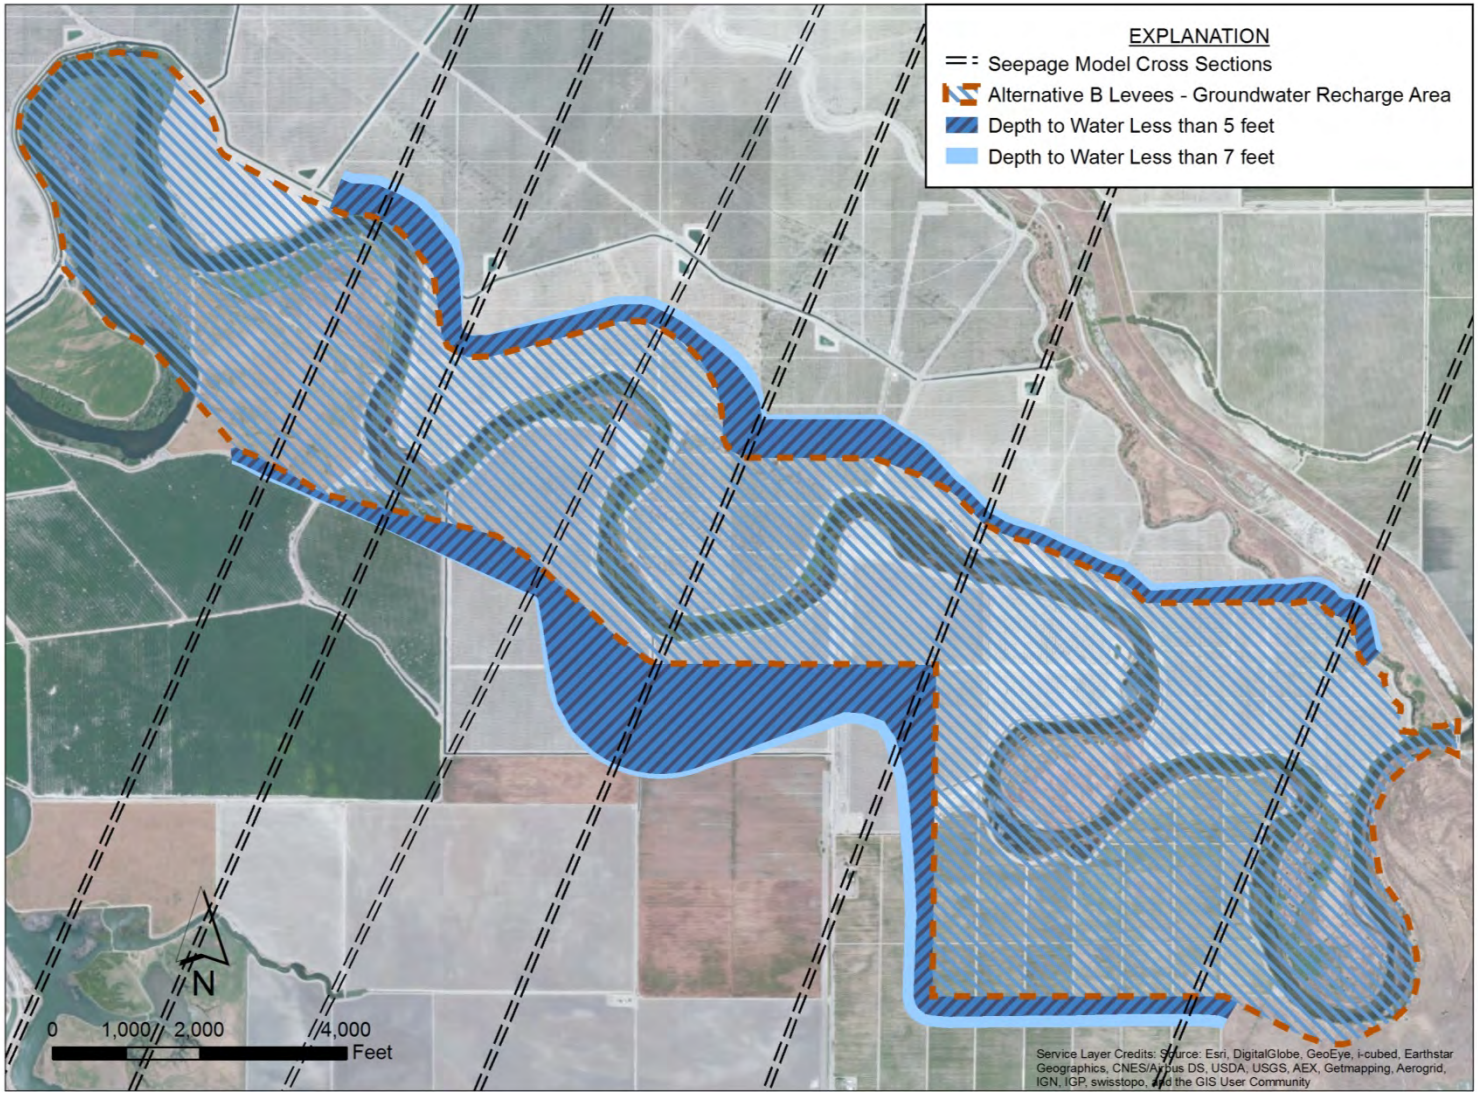

Figure 13-9.
Potential Areas with Depths to Groundwater Less than Monitoring Thresholds – Alternative B

Mitigation Measures GRW-1A and GRW-1B (Alternative C): ***Prepare and Implement a Stormwater Pollution Prevention Plan, Prepare and Implement a Construction Groundwater Management Plan.*** Refer to Mitigation Measures GRW-1A and GRW-1B (Alternative A). The same measures would be used here. Impacts would be **less than significant** after mitigation.

Impact GRW-2 (Alternative C): ***Long-term Changes in Groundwater Quality.*** Refer to Impact GRW-2 (Alternative A). Potential effects of Alternative C would be the same as potential effects of Alternative A, with the exception that agricultural practices would not occur on the floodplain. Conversion of previously irrigated agricultural lands into floodplain areas would reduce new sources of nutrients and pesticides that could influence groundwater quality locally. These effects would be **beneficial**.

Impact GRW-3 (Alternative C): ***Changes in Groundwater Levels.*** Refer to Impact GRW-3 (Alternative A). The impacts to groundwater levels for Alternative C would be the same as for Alternative A because both alternatives involve a narrow floodplain. These impacts would be **less than significant**.

Impact GRW-4 (Alternative C): ***Changes in Groundwater Recharge.*** Refer to Impact GRW-4 (Alternative A). Potential effects of Alternative C would be the same as potential effects of Alternative A. Increasing inundation areas and inundation frequencies would facilitate groundwater infiltration causing a **beneficial** effect on groundwater recharge.

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Alternative D would include construction of Project features including Fresno Slough Dam, a new levee system with a wide floodplain encompassing the river channel, and the North Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the North Canal bifurcation structure with fish passage facility and fish screen, removal of the San Joaquin River control structure at the Chowchilla Bifurcation Structure, removal of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 158-month timeframe. The Reach 2B floodplain would have an average width of approximately 4,200 feet.

Impact GRW-1 (Alternative D): ***Temporary Construction-Related Effects on Groundwater Quality.*** Construction associated with channel and structural improvements under Alternative D could temporary influence water quality, and could potentially lead to changes in groundwater quality. Refer to Impact GRW-1 (Alternative A). Potential impacts of Alternative D would be the same as potential impacts of Alternative A. These impacts would be **potentially significant**.

Mitigation Measures GRW-1A and GRW-1B (Alternative D): ***Prepare and Implement a Stormwater Pollution Prevention Plan, Prepare and Implement a Construction Groundwater Management Plan.*** Refer to Mitigation Measures GRW-1A and GRW-1B (Alternative A). The same measures would be used here. Impacts would be **less than significant** after mitigation.

Impact GRW-2 (Alternative D): ***Long-term Changes in Groundwater Quality.*** Refer to Impact GRW-2 (Alternative A). Potential effects of Alternative D would be the same as potential effects of Alternative A. Conversion of previously irrigated agricultural lands into floodplain areas would reduce new sources of nutrients and pesticides that could influence groundwater quality locally. These effects would be **beneficial**.

Impact GRW-3 (Alternative D): ***Changes in Groundwater Levels.*** Modeling results indicate the potential presence of shallow groundwater levels above the thresholds of 5- and 7-feet below ground surface along the edges of the San Joaquin River. Based on the model results, the area outside of the levee alignments with simulated depth to water less than 5 feet is 330 acres and an additional 70 acres have simulated depth of 5 to 7 feet below ground surface. Figure 13-10 shows the potential areas with depths to groundwater less than monitoring thresholds for the wide floodplain alternatives, including Alternative D. Similar to Alternative A, the model shows that infiltration and seepage from the river migrates primarily downward to the water table. The mound of groundwater produced from this infiltration and seepage does not extend more than 1,000 feet laterally from the river.

Through levee design features and seepage management measures, as described in Impact GRW-2 (Alternative A), potential adverse effects of an elevated groundwater level, such as waterlogging of crops and mobilizing of salts in the soil profile, would be avoided or substantially reduced in Alternative D. Compared to the No-Action Alternative, seepage impacts to adjacent lands under Alternative D are likely to be similar to or less than seepage impacts to adjacent lands under the No-Action Alternative.

Compared to existing conditions, groundwater levels would likely increase in areas immediately adjacent to San Joaquin River levees, however, seepage impacts would be avoided or substantially reduced by implementation of Project design features and seepage management measures. Therefore, these impacts would be **less than significant**.

Impact GRW-4 (Alternative D): ***Changes in Groundwater Recharge.*** Refer to Impact GRW-4 (Alternative A). Potential effects of Alternative D would be similar to potential effects of Alternative A, with the exception that the floodplain would have an average width of approximately 4,200 feet. Increasing inundation areas and inundation frequencies would facilitate groundwater infiltration causing a beneficial effect on groundwater recharge.

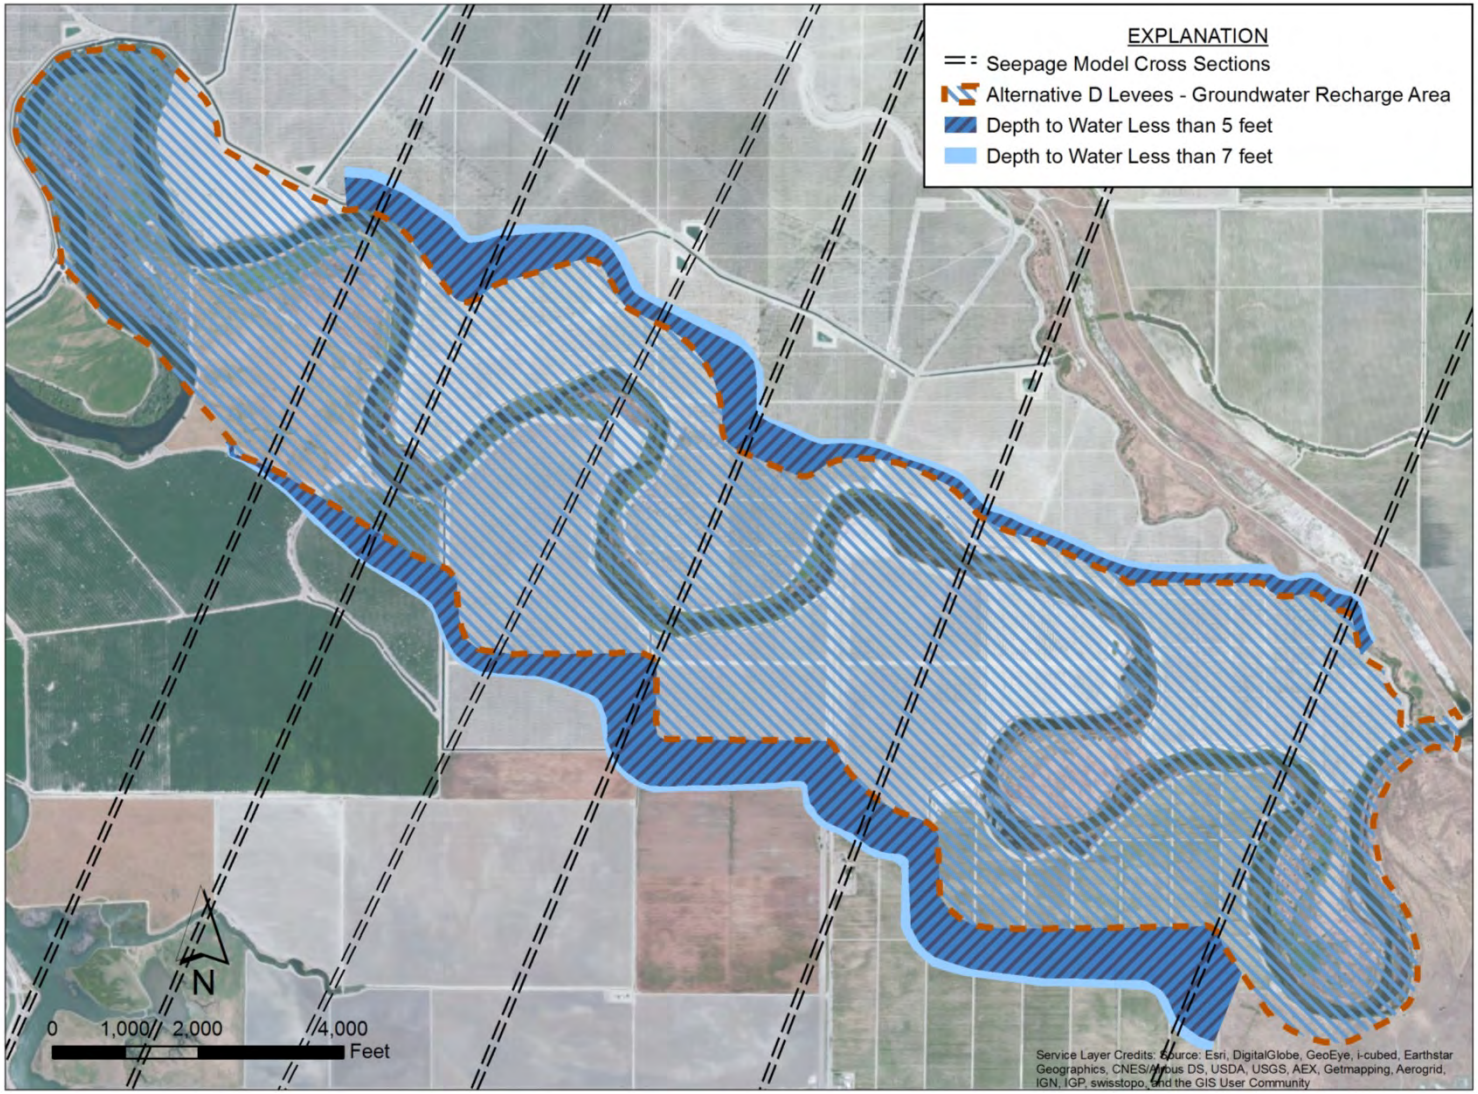

Figure 13-10.
Potential Areas with Depths to Groundwater Less than Monitoring Thresholds – Alternative D

14.0 Hydrology - Surface Water Resources and Water Quality

This section describes the potential impacts that implementation of Project alternatives may have on surface water resources and water quality at the Project area, and explains the environmental setting, applicable regulatory framework, and appropriate mitigation measures.

14.1 Environmental Setting

14.1.1 Physical Conditions

Reach 2B of the San Joaquin River is the 11.2-mile reach between the Chowchilla Bifurcation Structure (river mile [RM] 216) and Mendota Dam (RM 204.8). The Project footprint also includes areas outside of the immediate riparian corridor of Reach 2B that may be affected directly or indirectly by implementing Project alternatives. These areas include the existing levee-confined channel and overbank areas, areas below Mendota Dam, the Compact Bypass area and its discharge point at Reach 3, Fresno Slough, proposed canal alignments that would convey flows from an upstream point along Reach 2B to Fresno Slough, and potential upland borrow areas.

Areas outside of the current levee-contained channel, Mendota Pool, and Fresno Slough are primarily in agricultural production (e.g., alfalfa/field crops, winter vegetables, vineyards, orchards, livestock, etc.) with associated irrigation ditches, and public and private access roads.

Climate

The climate within the Project area and vicinity is semi-arid, with long, hot, dry summers and relatively mild winters. Winter temperatures on the San Joaquin valley floor are usually mild, but drop below freezing during occasional cold spells. Frost occurs in most fall/winter seasons, typically between late November and early March. Monthly average temperature based on long-term records for several weather stations are presented in Table 14-1. Based on these long-term records, the monthly average of the minimum daily temperature ranges from 36 to 66 degrees Fahrenheit (°F), and the monthly average of the maximum daily temperature ranges from 54 to 100°F.

Based on long-term records of precipitation, the average annual precipitation in the Project area is approximately 8.0 inches but increases moving easterly towards the mountains as the elevation increases (Table 14-2). Approximately 90 percent of precipitation in the Project area occurs from November through April. Heavy rainfall and snow in the western Sierra Nevada are the major sources of water in the San Joaquin River Basin. In the Sierra Nevada, the majority of the mean annual precipitation falls as snow and ranges from 20 inches in the foothills to over 80 inches at higher elevations.

The snow that remains after winter serves as stored water before it melts in the spring and summer.

14.1.2 Surface Water Resources

Reach 2B is located on the San Joaquin River between the Chowchilla Bifurcation Structure and Mendota Dam (see Figure 1-2). Major river systems that can contribute to flow to Reach 2B include the San Joaquin River and Kings River systems (Figure 14-1).

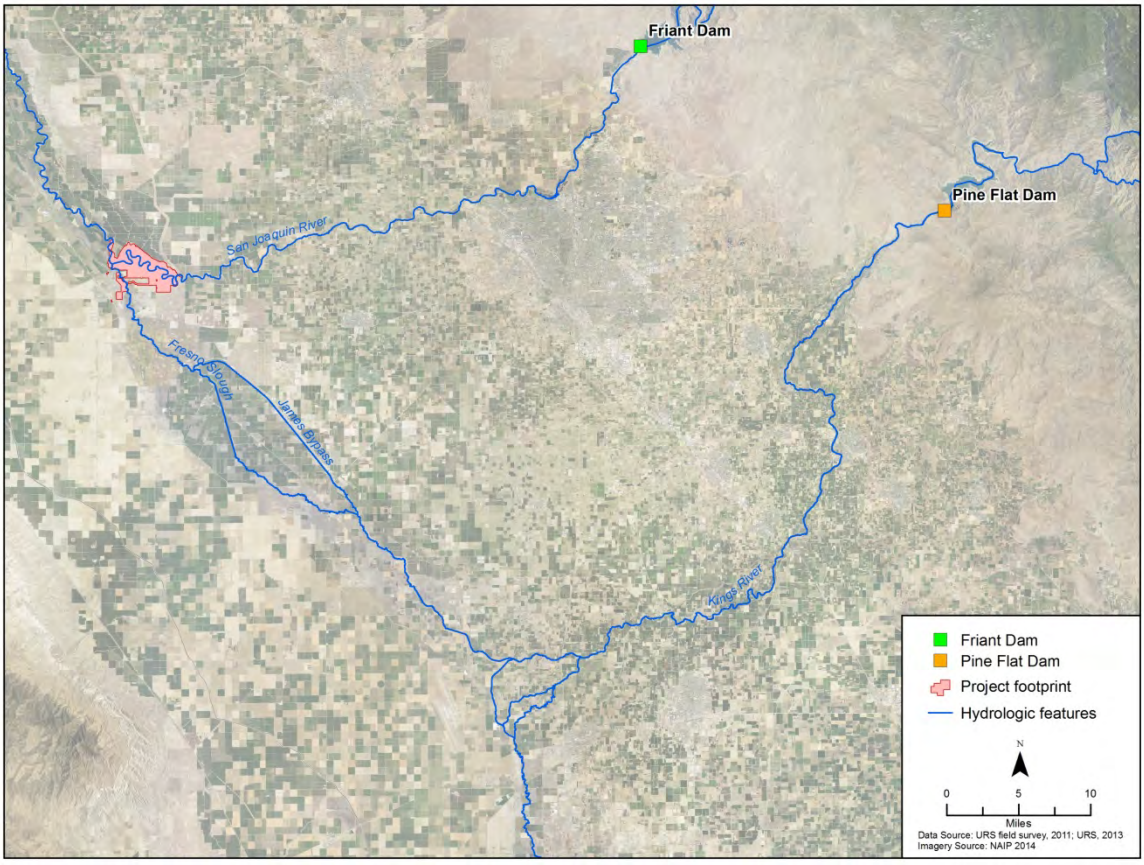

Figure 14-1.
Major River Systems Upstream of Reach 2B

San Joaquin River

The San Joaquin River flows generally northwest through the Central Valley before discharging into the Sacramento-San Joaquin Delta. Reach 2B is a segment of the San Joaquin River. This reach has a sandbed channel confined by earthen levees with an original design conveyance capacity of 2,500 cubic feet per second (cfs).

Flows in Reach 2B are almost entirely regulated by releases from Friant Dam. Friant Dam forms Millerton Lake and is located 51.6 miles upstream of Reach 2B at RM 267.6. Constructed in 1948 with a storage capacity of 520.5 thousand acre-feet (TAF), Millerton Lake provides irrigation water to agricultural users in Fresno, Madera, Kern and Tulare Counties through the Friant-Kern and Madera Canals (San Joaquin River Restoration Program [SJRRP] 2008). Releases from Millerton Lake to the San Joaquin River have typically ranged from 180 to 250 cfs during the May to October irrigation season and from 40 to 100 cfs during the winter (SJRRP 2009). Additional releases occur when the

170 TAF flood storage capacity of Millerton Lake is exceeded. The greatest risk of flooding occurs during warm rain-on-snow events in winter months or at the peak of the spring snowmelt. Prior to implementation of the Interim Flows program on October 1, 2009, flows up to 5,500 cfs were typically diverted to the Chowchilla Bypass at the Chowchilla Bifurcation Structure located at the upstream end of Reach 2B, although the operating rules allow discretion in passing first flows to the downstream river rather than into the Chowchilla Bypass. Flood flows reached the Mendota Pool at the lower end of Reach 2B in 1997, 2001, 2005, 2006, 2007, and 2011 (SJRRP 2009). Table 14-3 lists average, minimum, and maximum flow rates for several gaging stations in the Project area and vicinity. Figure 14-2 indicates the location of these gages.

Table 14-3.
Flow Averages and Ranges at Flow Stations in the Project Vicinity

Station (Station ID)	Period prior to Interim Flows			WY 2010 and 2011[a]	
	Average Flow (cfs)	Range of Flow (cfs)	Period	Average Flow (cfs)	Range of Flow (cfs)

Source: SJRRP 2011a, DWR 2011, USGS 2011

Notes:

[a] Includes both Interim Flows and flood flows.

[b] The period of record is from February 2010 to September 2011.

Key:

cfs = cubic feet per second

WY = water year

Prior to the Interim Flows program, the upper half of Reach 2B above the San Mateo Avenue crossing at RM 211.8 was generally dry and flow would reach Mendota Pool from Reach 2B only during periods of flood management releases. The lower half of Reach 2B (RM 204.8 to 211.8) is backwatered by Mendota Dam. With the exception of Fresno Slough which discharges flood flows from the Kings River system to Mendota Pool, there are no natural tributaries in Reach 2B. Agricultural return flows within the reach are reportedly minor (SJRRP 2009).

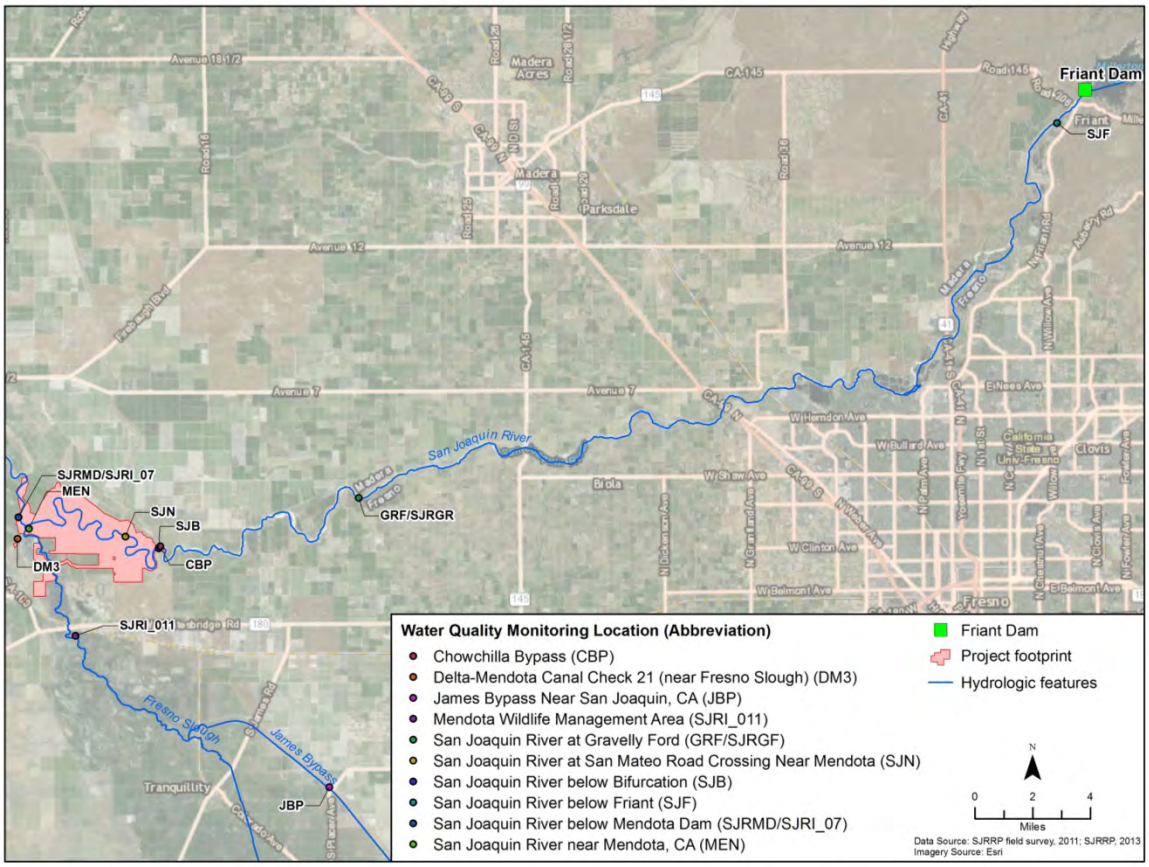

Figure 14-2.
Monitoring Locations

Seepage of river flows to shallow groundwater is generally considered detrimental to agricultural lands due to the potential for waterlogging crops, root-zone salinization, and levee instability (SJRRP 2011c). Seepage in Reach 2B has been observed at flows above 1,300 cfs when the Mendota Dam flashboards are in place (San Joaquin River Resources Management Coalition 2007). Seepage in Reach 2B caused by high flows can be reduced by removal of the flashboards and by opening the sluice gates at Mendota Dam. These sluice gates and flashboards can be manually opened or removed in advance of high-flow conditions. This process lowers the water level in the pool during high flow events to reduce seepage impacts to adjacent lands, but hinders distribution of flows into the irrigation canals. Additional information on the seepage issue and interaction between surface and groundwater is provided in Chapter 13.0, "Hydrology-Groundwater."

Chowchilla Bypass

The Chowchilla Bypass extends from the Chowchilla Bifurcation Structure to the Eastside Bypass at the confluence of Fresno River. The design channel capacity of the bypass near the San Joaquin River is 5,500 cfs. The bypass is an unlined channel constructed in highly permeable soils, and much of the initial flood flows infiltrate and recharge groundwater (U.S. Department of the Interior, Bureau of Reclamation [Reclamation] and California Department of Water Resources [DWR] 2005).

Mendota Pool

Mendota Dam was constructed in 1917 at RM 204.8. Mendota Pool is the reservoir created by Mendota Dam and has both a San Joaquin River arm and a Fresno Slough arm. The San Joaquin arm of Mendota Pool extends to the San Mateo Avenue crossing. The Fresno Slough arm of Mendota Pool extends several miles south of the Project area. The pool serves as a distribution point for irrigation water supplies delivered by the Delta-Mendota Canal (DMC) and for refuge water supply to the Mendota Wildlife Area. It has a capacity of 8 TAF, a surface area of approximately 2,000 acres when full, and varies in width from less than 100 to several hundred feet (SJRRP 2011d). During the summer irrigation season, the water-surface elevation in the pool is maintained at a depth of approximately 18 feet in the immediate vicinity of the dam, and water elevations generally fluctuate less than 6 inches. Upstream channel depths are typically only about 4 feet, generally decreasing in the upstream direction.

Mendota Pool provides no long-term storage for water supply operations or flood management. Mendota Pool is primarily filled by the DMC, which has a design capacity of 4,600 cfs but typically conveys 2,500 to 3,000 cfs from the Sacramento-San Joaquin Delta during the irrigation season. When the DMC is not in operation, flow at Mendota Dam can fall to zero. Mendota Pool is not intended for flood control; flashboards on the dam are removed prior to high-flow events. During spring flood events, average monthly flow at Mendota Dam can reach 2,600 cfs.

Mendota Pool delivers water to the San Joaquin River Exchange Contractors Water Authority, other Central Valley Project contractors, wildlife refuges and management areas, and State water contractors. Water delivered to Mendota Pool from the DMC is withdrawn at seven canal or pump locations in the pool, leaving about 500 cfs to be discharged down the San Joaquin River for delivery to the Arroyo Canal, which is located about 23 miles downstream from Mendota Dam (SJRRP 2011b, pages 11-9 and 13-22).

Fresno Slough/James Bypass

Fresno Slough is a distributary of the North Fork of the Kings River and is an intermittent stream that flows northwesterly to the Project area. James Bypass is a constructed channel that bypasses a portion of Fresno Slough. Flows in the North Fork of the Kings River consist primarily of flood releases from Pine Flat Dam located about 55 miles to the east. Under current operational requirements, Kings River flood flows can enter Mendota Pool via Fresno Slough/James Bypass. Flows from the Kings River are regulated by Pine Flat Dam releases and the Crescent Weir, which are operated by the Kings River Conservation District. Pine Flat Dam has routed surplus flows through Fresno Slough/James Bypass in 20 of 53 years of operation (U.S. Environmental Protection Agency [EPA] 2007). Reclamation supplements natural flow from Fresno Slough/James Bypass and San Joaquin River into Mendota Pool with deliveries from the DMC to satisfy water supply contracts.

Interim Flows Program

The Interim Flows program began at the start of water year[1] 2010 and involves the release of 350 to 1,660 cfs from Friant Dam with a maximum flow of 1,300 cfs at the upstream end of Reach 2B in spring. These experimental flows have provided valuable information regarding temperatures, fish needs, seepage losses, shallow groundwater conditions, recirculation, recapture and reuse conditions, channel capacity, and levee stability. Restoration Flows were released starting on January 1, 2014. Restoration Flows are limited to the existing conveyance capacity of the reach.

Water Rights

Reclamation holds most of the water rights on the San Joaquin River, allowing diversion of water at Friant Dam pursuant to water rights permits and license. In order to facilitate exercise of these rights, purchase and exchange agreements have been executed involving water rights existing at the time the Central Valley Project was developed. The Exchange Contract provides for an annual delivery of approximately 850 TAF of water, subject to shortage provisions, to water right holders along the San Joaquin River in exchange for not exercising rights to divert from the San Joaquin River. This exchange is met with Delta deliveries from the DMC. If sufficient water from the DMC were not available for the exchange, Reclamation would need to make flows available from the San Joaquin River. With the exception of flood flows and releases made in compliance with Public Law 111-11, water passing Friant Dam is limited to that necessary to maintain the 5 cfs flow requirement at Gravelly Ford pursuant to various Holding Contracts.

14.1.3 Geomorphology

The San Joaquin River in Reach 2B is characterized by a single-thread, meandering, sand-bed channel that is bounded by local levees and a relatively flat overbank surface (Figure 14-3). The approximately 11.2-mile reach has a sinuosity[2] of about 2.2, the highest of any portion of the overall Restoration Area (Figure 14-4). The high sinuosity results from a combination of natural and man-induced factors. Geologically driven subsidence of the San Joaquin Valley, primarily downstream from Mendota Dam, is ongoing at a rate of about 0.25 millimeters (0.01 inch) per year (Ouchi 1983), and this rate accelerated significantly beginning in the 1920s due to human-induced subsidence associated with groundwater withdrawal and hydrocompaction of the soils by irrigation (Poland et al. 1975, Bull 1964, Sneed et al. 2013). (Subsidence is discussed further in Chapter 11.0, "Geology and Soils" and Chapter 13.0, "Hydrology – Groundwater.") The general alignment of the river down the dip slope of the subsiding basin causes the valley floor in Reach 2B to be steeper than in the up- and downstream reaches (Figure 14-5). The high sinuosity represents the historic adjustment of the river slope to achieve sediment-transport balance with the upstream sediment supply through lengthening of the channel.

[1] Most hydrologic monitoring occurs for a period defined as a water year, which begins on October 1 and ends on September 30 of the named year. For example, water year 2010 began on October 1, 2009 and concluded on September 30, 2010.

[2] Sinuosity is defined as the ratio of length along the river to the approximate straight-line distance down the valley.

Comparison of the river maps prepared by the California Debris Commission in 1914 with current aerial photography and mapping indicates that there has been very little change in the channel alignment since at least the early 20th century (Figure 14-3 [bottom]), even though the river continued to see relatively high flows on a regular basis until completion of Friant Dam in the 1940s (Figure 14-6). Although the scale and resolution do not permit direct comparison with the current river alignment, mapping from the mid-1800s by the General Land Office and the 1880s by William Hammond Hall indicate that this reach had a meandering planform similar to the existing planform even at that time.

Figure 14-6.
Mean Daily Flow Duration Curves at the Friant Gage under Full Natural Flow, Pre-Friant Dam and Post-Friant Dam Conditions

The main channel in Reach 2B typically has a wide, relatively shallow cross-section shape, with bed material that is generally in the medium- to coarse-sand size range (Figures 14-7 and 14-8). Channel widths in the portions of the reach outside the backwater effects of Mendota Dam are in the range of 200 to 400 feet, and average about 250 feet (Figure 14-9). Based on one-dimensional hydraulic modeling using the 2009 LiDAR (Light Detection and Ranging) data, typical cross-sectionally averaged flow depths at discharges in the range of the restoration releases vary from 2.5 to 7 feet, averaging 4 feet at 1,250 cfs and about 6 feet at 2,000 cfs (Figure 14-10).[3] The hydraulic model results also indicate that the bankfull capacity (based on the ground overbank elevations outside the local levees)[4] is about 1,600 cfs in the downstream portion of the reach between San Mateo Avenue and the head of Mendota Pool and about 2,100 cfs in the upstream portion of the reach between San Mateo Avenue and the Chowchilla Bifurcation Structure (Figure 14-11).

The lower capacity downstream from San Mateo Avenue is caused by a combination of sediment deposition and areas of relatively thick instream and riparian vegetation both associated with backwater effects from Mendota Dam (Figures 14-12 and 14-13). San Mateo Avenue is currently a low-water crossing with an approximately 5-foot-diameter culvert through the embankment that begins to overtop at less than 320 cfs. This crossing

[3] Note that the depth varies outside this range in local areas.
[4] The bankfull capacity occurs where the stream completely fills its channel at maximum capacity.

provides grade control and has a limited effect on the upstream water-surface profile and associated hydraulic conditions.

Figure 14-13.
Main Channel Cross Section Profile about 500 feet Downstream from San Mateo Avenue, in the Area Shown in Figure 12 (Downstream View)

Based on hydraulic modeling using the topography from the 1914 California Debris Commission mapping, the in-channel capacity was about 2,500 cfs, 20 to 30 percent higher than the existing capacity. Although a significant amount of the sediment carried by the river from upstream has been diverted into the Chowchilla Bypass since construction of the flood-control system in the 1960s (as evidenced by the approximately 200,000 cubic yard sediment trap in the Chowchilla Bypass just downstream of the Chowchilla Bifurcation Structure [Figure 14-14]), sediment-continuity analysis by Tetra Tech (2011) and sediment-transport modeling by Reclamation (2011) indicate that Reach 2B is slightly aggradational[5] under existing conditions. This aggradation, coupled with the thick in-channel vegetation downstream from San Mateo Avenue, is the likely cause of the decrease in channel capacity over the past century.

[5] The streambed is being elevated slightly due to sediment deposition.

Figure 14-14.
View of 200,000 Cubic Yard Sediment Trap in the Chowchilla Bypass just Downstream from the Chowchilla Bifurcation Structure

The geomorphic literature indicates that the bankfull capacity in self-adjusted channels is typically in the range of the mean annual (i.e., 1.5- to 2-year) flood peak, although this can vary widely from less than the 1.5-year up to the 5-year or higher flood peak, depending on local conditions (Williams 1978, Wolman and Miller 1960). The 2-year flood peak under unregulated conditions was approximately 11,000 cfs (U.S. Army Corps of Engineers [Corps] and DWR 2002), and the discharge at the Friant gage, located about 50 miles upstream from the head of Reach 2B,[6] exceeded 2,500 cfs about 30 percent of the time (or about 110 days per year, on average) prior to significant water-resources development in the basin (Corps and DWR 2002) (see Figure 14-6). The duration of flows above 2,500 cfs decreased only slightly, to about 100 days per year during the early part of the 20th century, as water-resources development continued to occur prior to construction of Friant Dam. The overbanks were, thus, inundated for extended periods of time essentially every year, with flow passing from the main channel into a series of distributary channels, including Lone Willow Slough in the vicinity of the Chowchilla Bifurcation Structure. The locations of these distributary channels in the San Joaquin River floodplain can be clearly seen in the detailed National Resources Conservation Service (NRCS) (1990 and 2006) soils mapping, particularly on the north side of the river (see Hydrologic Soils Group [HSG] A soils in Figure 14-15).

[6] Although flow losses of up to 250 cfs occur in the 50-mile reach, these losses are less significant at higher flows; thus, the high flow data from the Friant gage are reasonably representative of flows reaching the head of Reach 2B.

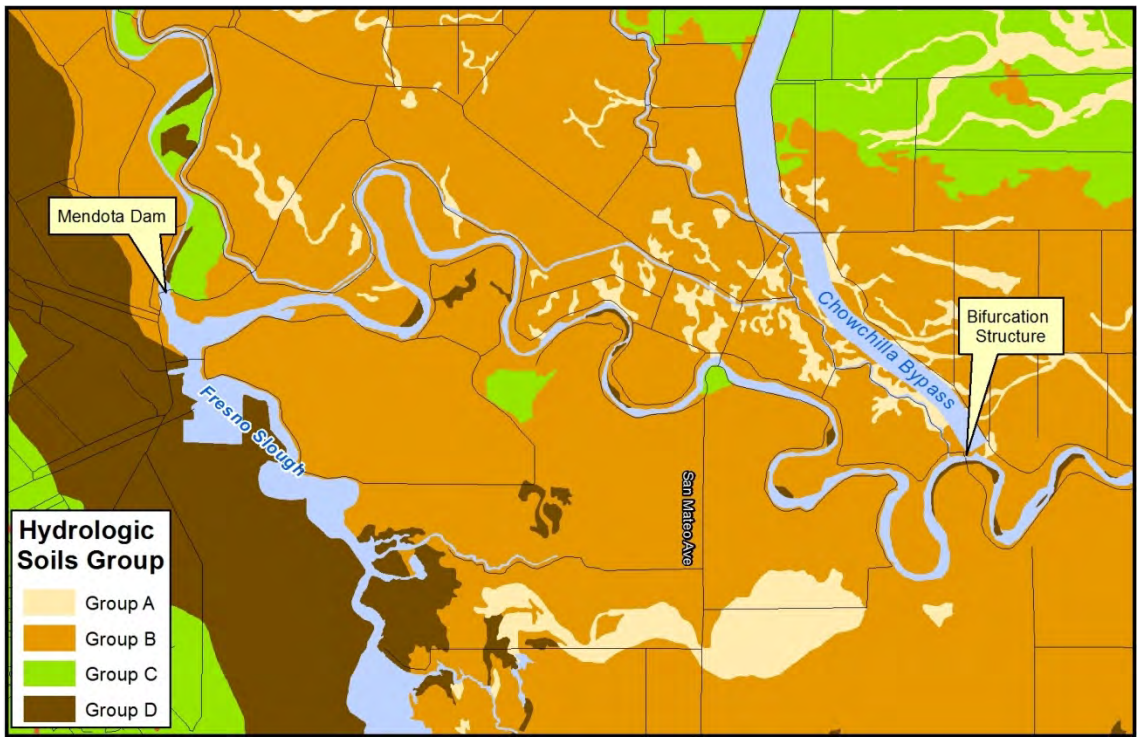

Figure 14-15.
Hydrologic Soil Groups in Floodplain of Reach 2B

According to Ouchi (1983), the reach from about Gravelly Ford downstream through Reach 2B is the modern-day alluvial fan of the San Joaquin River which explains the presence of the distributary channels and low main channel capacity. The cross-valley profile near the head of Reach 2B, in which the topography generally slopes downward away from the river, is consistent with the anticipated profile of a valley-floor fan, corroborating the conclusions of Ouchi (1983) (Figure 14-16).

Most of the floodplain soils along Reach 2B outside the overflow channels are categorized as HSG B, which means that they are typically composed of loamy sand or sandy loam with 10- to 20-percent clay and 50- to 90-percent sand. These soils have moderately low runoff potential when wet and are moderately susceptible to erosion. The HSG A soils tend to contain a greater percentage of sand, reflecting the higher flow energy in the overflow channels, compared to the floodplain areas outside these channels. These soils provide excellent growth media for riparian vegetation where they are exposed in the river banks which accounts for the limited amount of bank erosion and channel migration that has occurred since the mid- to late-1800s. The presence of the HSG A soils suggest that the overbank soils that would be the foundation for any future levees along the reach are highly variable, a factor that will be very important in designing the levee foundations.

14.1.4 Water Quality

The primary source of water at the upstream end of Reach 2B (i.e., releases from Friant Dam) is generally considered very good in terms of water quality, having low temperature, low salinity, high dissolved oxygen, low nutrient concentrations, and no known problems with trace elements or pesticides (McBain and Trush, Inc. 2002). However, surface water quality in the Project area can be degraded due to low river flows, agricultural operations, and illegal dumping, resulting in increased concentrations of salts, pesticides, nutrients (from fertilizers), and trash and debris. Percolating rainfall and excess irrigation water leach these constituents downwards from fields into the shallow aquifer; the shallow aquifer has a hydrologic connection to local ditches, canals and the river. Stormwater runoff and agricultural return flows mobilize the same set of contaminants from fields into local receiving waters. Deliveries of Sacramento-San Joaquin Delta water to Mendota Pool via the DMC also affect water quality in the lower part of the Project area. In addition, abandoned mill and mine sites in the New Idria mining area of San Benito County within the Kings River/Fresno Slough watershed may contribute mercury and arsenic to Mendota Pool.

Table 14-4 lists general water quality indicator data for several stations in the vicinity of Reach 2B. Electrical conductivity (EC), expressed in microsiemens per centimeter (µS/cm), is used as a proxy for salinity since EC concentrations increase with increasing salt concentrations and EC is generally proportional to salinity. Stations on the San Joaquin River at Gravelly Ford (above Reach 2B) and below the Chowchilla Bifurcation

(at the upstream end of Reach 2B) (i.e., stations GRF and SJB) are distinguished from lower stations by their relatively low EC with average concentrations of 44 µS/cm and 45 µS/cm respectively. The DMC (station DM3), with an average EC concentration of 510 µS/cm, is the primary source of water for the Mendota Pool. The impact of DMC imports on San Joaquin River water quality is evident at the San Joaquin River station near Mendota where average EC concentrations were 465 µS/cm (from April 1951 to September 1984) and 329 µS/cm (from November 2009 to September 2011). A similar pattern between upstream and downstream stations is seen with pH data (but not turbidity); however, pH and turbidity measurements were not reported for DM3.

A more extensive suite of constituents (including total suspended solids, nutrients, total and dissolved organic carbon, bacteria, and trace elements) have been monitored monthly by the Interim Flows program beginning October 2009. The program targets several stations along the San Joaquin River including San Joaquin River at Gravelly Ford and San Joaquin River below Mendota Dam (SJRRP 2013). Average concentrations of select parameters are listed for these stations in Table 14-5. In general, concentrations of total suspended solids, nutrients, boron, chromium, copper, mercury, nickel, selenium, and zinc are higher at the downstream station (below Mendota Dam) compared to the upstream station (Gravelly Ford).

The Interim Flows program also sampled for a large suite of pesticides (organochlorine, pyrethroids, carbamates, organophosphates) on April 6, 2011. The only pesticide that exceeded detection limits was alpha-hexachlorocyclohexane (alpha-HCH), an organochlorine pesticide which was measured at San Joaquin River below Mendota Dam at a concentration of 0.002 micrograms per liter (µg/L). The compound alpha-HCH is a byproduct of the production of the insecticide lindane. There are no aquatic life water quality objectives for alpha-HCH; however, the California Toxics Rule (CTR) drinking water criteria for the protection of human health (30-day average) is 0.0039 µg/L.

Sediment Quality

As part of the Interim Flows program, bed sediment samples collected at target stations in fall and winter 2009 and spring 2010 were analyzed for metals, trace elements, and toxicity. More comprehensive sediment sampling was conducted in fall/winter 2011 by the SJRRP to characterize sediments in Mendota Pool, many of which are expected to erode from the existing pool area as a result of Project alternatives which lower Mendota Dam (SJRRP 2011e, SJRRP 2012). A total of 13 volume-proportional composite samples were collected from drill holes advanced between Mendota Dam and 4.7 miles upstream in the San Joaquin river arm of Mendota Pool, including a background sample composited from sediment collected between approximately RM 206.5 and RM 209.5. Elutriate[7] was sampled to estimate the concentrations of chemicals that are likely to be released to the water column should Mendota Pool sediments become suspended or transported. Sediment and elutriate samples were analyzed for physical properties, "constituents of potential concern" (metals, pesticides, and organic compounds), and acute toxicity.

Analytical results from the 2009/2010 Interim Flows program and the 2011 SJRRP study were compared to several applicable sediment and water quality standards to identify chemicals that may be present at potentially harmful concentrations to freshwater aquatic life and human health (SJRRP 2012). Sediment concentrations of some constituents exceed one or more of the screening quick reference tables toxicity thresholds that predict "unlikely" adverse sediment impacts, including four metals (arsenic, chromium, copper, and nickel) and two organic pesticides (4,4'-dichlorodiphenyldichloroethane [DDD] and 4,4'-dichlorodiphenyldichloroethylene [DDE]). However, toxicity test results did not show significantly increased mortality of test organisms, and no chemical analytes were detected at concentrations exceeding Dredged Material Management Program Disposal Procedures Users' Manual bioaccumulation triggers; therefore, the SJRRP study concluded that sediment within Mendota Pool is not likely to have an adverse effect on the benthic community (SJRRP 2012).

Concentrations of several constituents in the elutriate exceeded water quality objectives from the Water Quality Control Plan for the Sacramento and San Joaquin River Basins (Basin Plan) and CTR water quality standards. These include EC, ammonia as nitrogen, metals (aluminum, arsenic, barium, cadmium, copper, iron, lead, manganese, mercury, and molybdenum) and organic pesticides (4,4'-DDD, total DDD, 4,4'-DDE, and total DDE). In addition, toxicity tests on elutriate samples from lower- and middle-pool regions showed significant reductions in survival of test organisms. Based on these findings, the SJRRP study concluded that Mendota Pool sediment suspended in the water column could increase chemical concentrations to levels that violate promulgated Basin Plan objectives and CTR water quality standards (SJRRP 2012).

[7] Elutriate is formed by vigorously mixing one part sediment to four parts water, allowing the mixture to settle, and then centrifuging to remove particulates. The resulting fluid is termed "elutriate."

Beneficial Uses and Listed Waterbodies

The beneficial uses designated by the Central Valley Regional Water Quality Control Board (RWQCB) for the San Joaquin River between Friant Dam and the Mendota Pool include the following (RWQCB 2011):

- Municipal and domestic supply.
- Agriculture irrigation and stock watering.
- Industrial process supply.
- Contact and non-contact water recreation.
- Warm and cold freshwater habitat.
- Migration of aquatic organisms (warm and cold).
- Spawning, reproduction, and/or early development.
- Wildlife habitat.

No beneficial uses have been specifically designated for Fresno Slough. State policy, however, is that the beneficial uses for a specific water body generally apply to its tributaries.

San Joaquin River between Friant Dam and Mendota Pool is identified on the Clean Water Act (CWA) Section 303(d) list as impaired by invasive species with an unknown source. The Total Maximum Daily Load (TMDL) plan to correct the impairment is scheduled for completion in 2019. Mendota Pool is listed as impaired by mercury caused by resource extraction; TMDL completion is scheduled for 2021. Mendota Pool is also listed for selenium with agriculture, agricultural return flows, and groundwater withdrawal identified as potential sources; TMDL completion is scheduled for 2019. The reach of the San Joaquin River immediately downstream of Reach 2B, between the Mendota Pool and Bear Creek, is listed for boron, chlorpyrifos, dichlorodiphenyl-trichloroethane (DDT), diazinon, EC, Group A (restricted) pesticides, and unknown toxicity. Agriculture is identified as the potential source for all of these pollutants except unknown toxicity, for which the source is unknown. A TMDL for diazinon and chlopyrifos was approved by the EPA in December 2006.

14.2 Regulatory Setting

This section focuses on laws related directly to surface water and water quality. The majority of this discussion is taken directly from the Program Environmental Impact Statement/Report (PEIS/R) (SJRRP 2011b, pages 14-7 to 14-11). A number of regulatory authorities at the Federal, State, and local levels control the flow, quality and supply of water in California, either directly or indirectly. At the State level, the State Water Resources Control Board (SWRCB) and the Central Valley RWQCB regulate water quality in San Joaquin River. The EPA also plays an important role under the auspices of the Federal CWA and Safe Drinking Water Act. The California Department of Health

Services (DHS) has an interest in the Delta because the Delta is the source of drinking water for over 25 million Californians.

14.2.1 Federal

This section presents the applicable Federal regulations associated with surface water and water quality.

Safe Drinking Water Act

The Safe Drinking Water Act was established to protect the quality of drinking water in the United States. The Safe Drinking Water Act authorized EPA to set National health-based standards for drinking water, and requires many actions to protect drinking water and its sources, including rivers, lakes, reservoirs, springs, and groundwater wells. Furthermore, the Safe Drinking Water Act requires all owners or operators of public water systems to comply with primary (health-related) standards. EPA has delegated to the DHS, Division of Drinking Water and Environmental Management, the responsibility for administering California's drinking-water program.

Clean Water Act

The CWA is the primary Federal legislation governing the water quality aspects of the Project. The objective of the act is "to restore and maintain the chemical, physical, and biological integrity of the nation's waters." The CWA establishes the basic structure for regulating discharge of pollutants into the waters of the United States and gives EPA the authority to implement pollution control programs such as setting wastewater standards for industries. In certain states such as California, EPA has delegated authority to state agencies.

Section 303. Section 303 of the CWA requires states to adopt water quality standards for all surface waters of the United States. The three major components of water quality standards are designated users, water quality criteria, and antidegradation policy. Section 303(d) of the CWA requires states and authorized Native American tribes to develop a list of water-quality-impaired segments of waterways. The list includes waters that do not meet water quality standards necessary to support the beneficial uses of a waterway, even after point sources of pollution have installed the minimum required levels of pollution control technology. Only waters impaired by "pollutants" (including clean sediments, nutrients such as nitrogen and phosphorus, pathogens, acids/bases, temperature, metals, cyanide, and synthetic organic chemicals, not those impaired by other types of "pollution" (e.g., altered flow, channel modification), are to be included on the list.

Section 303(d). Section 303(d) of the CWA also requires states to maintain a list of impaired water bodies so that a TMDL can be established. A TMDL is a plan to restore the beneficial uses of a stream or to otherwise correct an impairment. It establishes the allowable pollutant loadings or other quantifiable parameters (e.g., pH, temperature) for a water body and thereby provides the basis for establishing water quality-based controls. The calculation for establishing TMDLs for each water body must include a margin of safety to ensure that the water body can be used for the purposes of State designation. Additionally, the calculation also must account for seasonal variation in water quality.

Central Valley RWQCB develops TMDLs for the San Joaquin River (see discussion on the Porter-Cologne Water Quality Control Act below).

Section 401. Section 401 of the CWA requires Federal agencies to obtain certification from the State or Native American tribes before issuing permits that would result in increased pollutant loads to a water body. The certification is issued only if such increased loads would not cause or contribute to exceedances of water quality standards.

Section 402. Section 402 of the CWA creates the National Pollutant Discharge Elimination System (NPDES) permit program. This program covers point sources of pollution discharging into a surface water body.

Section 404. A permit must be obtained from the Corps under Section 404 of the CWA for the discharge of dredged or fill material into "waters of the United States, including wetlands." Waters of the United States include wetlands and lakes, rivers, streams, and their tributaries. Wetlands are defined for regulatory purposes as areas inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support and, under normal circumstances do support, vegetation typically adapted for life in saturated soil conditions.

Antidegradation Policy

The Antidegradation Policy, established in 1968 and revised in 2005 (40 Code of Federal Regulations [CFR], Section 131.12), is designed to protect existing uses and water quality and National water resources, as authorized by Section 303(c) of the CWA. This policy protects water bodies where existing quality is higher than necessary for protection of beneficial uses. It states that high quality waters will be maintained unless a change in water quality is (1) consistent with maximum benefit to the people of the State, (2) will not unreasonably affect present and anticipated beneficial uses of the water, and (3) will not result in water quality less than that prescribed in policies.

Rivers and Harbors Act Section 10

Section 10 of the Rivers and Harbors Act (33 United States Code 401 et seq.) requires authorization from the Corps for construction of any structure over, in, or under navigable waters of the United States.

National Flood Insurance Program

The Federal Emergency Management Agency (FEMA) is responsible for determining flood elevations and floodplain boundaries and distributing Flood Insurance Rate Maps, which are used in the National Flood Insurance Program. Flood Insurance Rate Maps identify the locations of special flood hazard areas, including the 100-year and 500-year floodplain. Federal regulations governing development in a Zone A (100-year) floodplain are set forth in 44 CFR, Part 60, which enables FEMA to require municipalities that participate in the National Flood Insurance Program to adopt certain flood hazard reduction standards for construction and development within floodplains. In the Project area and vicinity, the FEMA program is overseen by the Fresno County Department of Public Works and Planning Development Engineering Section and the Madera County Flood Control and Water Conservation District.

Federal Insecticide, Fungicide, and Rodenticide Act

The Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) was first passed in 1947 to establish labeling provisions and procedures for registering pesticides with the U.S. Department of Agriculture. It was rewritten in 1972 and has since been amended several times. In its current form, FIFRA mandates that EPA regulate the use and sale of pesticides to protect human health and preserve the environment. Registration with the EPA assures that pesticides would be properly labeled and that, if used in accordance with specifications, they would not cause unreasonable harm to the environment. Pesticide use in California is also regulated by the California Department of Pesticide Regulation (DPR) and local County Agricultural Commissioners.

14.2.2 State of California

This section presents the applicable State regulations associated with surface water quality.

Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act is California's statutory authority for protecting water quality. Under the act, the State must adopt water quality policies, plans, and objectives protecting the State's waters for the use and enjoyment of people. Obligations of SWRCB and the RWQCBs to adopt and periodically update their Water Quality Control Plans (e.g., Basin Plans) are set forth in the act. A Basin Plan identifies the designated beneficial uses for specific surface water and groundwater resources, applicable water quality objectives necessary to support the beneficial uses, and implementation programs that are established to maintain and protect water quality from degradation for each of the RWQCBs. The act also requires waste dischargers to notify the RWQCBs of their activities through filing reports of waste discharge, and authorizes SWRCB and the RWQCBs to issue and enforce waste discharge requirement, NPDES permits, Section 401 water quality certifications, or other approvals. The RWQCBs also have authority to issue waivers for waste discharge reports/waste discharge requirements for broad categories of "low threat" discharge activities that have minimal potential for adverse water quality effects when implemented according to prescribed terms and conditions.

Water quality objectives established in the Basin Plan for the Sacramento River and San Joaquin River Basins (RWQCB 2011) to protect the beneficial uses from the types of potential pollutants that could be generated by the Project are included in Table 14-6.

Table 14-6.
Basin Plan Water Quality Objectives to Protect Beneficial Uses

Parameter	Water Quality Objective
Dissolved Oxygen	5.0 mg/L minimum in waters designated WARM 7.0 mg/L minimum in waters designated COLD 7.0 mg/L minimum in waters designated SPWN The monthly median of the mean daily dissolved oxygen concentration shall not fall below 85 percent of saturation in the main water mass, and the 95 percentile concentration shall not fall below 75 percent saturation.
Salinity	Electrical conductivity shall not exceed 150 µS/cm from Friant Dam to Gravelly Ford.
Suspended Material and Settleable Material	Waters shall not contain substances or suspended material in concentrations that cause nuisance or adversely affect beneficial uses.
Sediment	The suspended sediment load and suspended sediment discharge rate of surface waters shall not be altered in such a manner as to cause nuisance or adversely affect beneficial uses.
Turbidity	Waters shall be free of changes in turbidity that cause nuisance or adversely affect beneficial uses. Increases in turbidity attributable to controllable water quality factors shall not exceed: 1 NTU where natural turbidity is between 0 and 5 NTUs; 20 percent where natural turbidity is between 5 and 50 NTUs; 10 NTUs where natural turbidity is between 50 and 100 NTUs; or 10 percent where natural turbidity is greater than 100 NTUs.
pH	The pH shall not be depressed below 6.5 nor raised above 8.5. Changes in normal ambient pH levels shall not exceed 0.5 in fresh waters designated with COLD or WARM beneficial uses.
Oil and Grease	Waters shall not contain oils, greases, waxes, or other materials in concentrations that cause nuisance, result in visible film or coating on the surface of the water or on objects in the water, or that otherwise adversely affect beneficial uses.
Floating Material	Waters shall not contain floating material in amounts that cause nuisance or adversely affect beneficial uses.
Temperature	The natural receiving water temperature intrastate waters shall not be altered unless it can be demonstrated that such alteration in temperature does not adversely affect beneficial uses. At no time or place shall the temperature of COLD or WARM intrastate waters be increased more than 5ºF (2.8ºC) above natural receiving water temperature.
Toxicity	All waters shall be maintained free of toxic substances in concentrations that produce detrimental physiological responses in human, plant, animal, or aquatic life. This objective applies regardless of whether the toxicity is caused by a single substance or the interactive effect of multiple substances. Compliance with this objective would be determined by analyses of indicator organisms, species diversity, population density, growth anomalies, and biotoxicity tests of appropriate duration or other methods as specified by the RWQCB
Pesticides	No individual pesticide or combination of pesticides shall be present in concentrations that adversely affect beneficial uses. Below Mendota Dam, the following objectives apply and should not be exceeded more than once in a three year period. Chlorpyrifos: 0.025 µg/L (1-hour average), 0.015 µg/L (4-day average) Diazinon: 0.16 µg/L (1-hour average), 0.10 µg/L (4-day average)

Source: RWQCB 2011

Key:

ºC = degree Celsius
ºF = degree Fahrenheit
µg/L = microgram per liter
µS/cm = microsiemen per centimeter
mg/L = miligrams per liter
NTU = nephelometric turbidity unit
RWQCB = Regional Water Quality Control Board

California Toxics Rule

On May 18, 2000, the EPA published the CTR in the Federal Register, adding Section 131.38 to 40 CFR and establishing new water quality objectives for some constituents in the Basin Plans. On May 22, 2000, the Office of Administrative Law approved, with modifications, the Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California (Phase 1 of the Inland Surface Waters Plan and Enclosed Bays and Estuaries Plan). The Policy establishes implementation procedures for three categories of priority pollutant criteria or water quality objectives. These are:

- Criteria promulgated by the EPA in the National Toxics Rule that apply in California.
- Criteria proposed by the EPA in the CTR.
- Water quality objectives contained in RWQCB Basin Plans.

NPDES General Permit for Storm Water Discharges Associated with Construction and Land Disturbance Activities

Construction activities on 1 acre or more are subject to the permitting requirements of the *NPDES General Permit for Storm Water Discharges Associated with Construction and Land Disturbance Activities* (Construction General Permit) Order No. 2009-0009-DWQ, NPDES No. CAS000002 (SWRCB 2009). The SWRCB established the Construction General Permit program to regulate stormwater discharges from construction sites. The Construction General Permit implements a risk-based permitting approach, specifies minimum best management practice (BMP) requirements, and requires monitoring and reporting activities. The Construction General Permit establishes three project risk levels that are based on site erosion and receiving-water risk factors. Risk Levels 1, 2, and 3 correspond to low-, medium-, and high-risk levels for a project. A preliminary analysis indicates that the Project is likely to be categorized as either Risk Level 2 or 3 depending on the construction schedule.

The Construction General Permit requires preparation and implementation of a stormwater pollution prevention plan (SWPPP), which would provide BMPs to minimize potential short-term increases in transport of sediment and other pollutants caused by construction. Typical BMPs include:

- Implementing practices to minimize the contact of construction materials, equipment, and maintenance supplies with stormwater.
- Limiting fueling and other activities using hazardous materials to designated areas, providing drip pans under equipment, and daily checks for vehicle condition.
- Implementing practices to reduce erosion of exposed soil, including stabilization for soil stockpiles, watering for dust control, perimeter silt fences, and/or placement of fiber rolls.
- Implementing practices to maintain water quality including silt fences, stabilized construction entrances, and storm drain inlet protection.

- Implementing practices to capture and provide proper offsite disposal of concrete washwater, including isolation of runoff from fresh concrete during curing to prevent it from reaching the local drainage system.
- Developing spill prevention and emergency response plans to handle potential fuel or other spills.
- Where feasible, limiting construction to dry periods.

Waste Discharge Requirements for Dewatering and Other Low Threat Discharges to Surface Waters

The General Order for *Dewatering and Other Low Threat Discharges to Surface Waters*, RWQCB Order No. R5-2008-0081, is a general permit covering discharges of construction dewatering under the following circumstances: the discharge does "not contain significant quantities of pollutants and they are either (1) four months or less in duration, or (2) the average dry weather discharge does not exceed 0.25 million gallons per day."

California Water Code (Water Rights)

A water right is a legally protected right, granted by law, to take control of water and to put it to beneficial use. Under the California Water Code, the SWRCB is responsible for allocating surface water rights and permitting the diversion and use of water throughout the State. Through its Division of Water Rights, the SWRCB issues permits to store and to divert water for new appropriations and it authorizes changes to existing water rights. SWRCB attaches conditions to these permits to ensure that the water user prevents waste, conserves water, does not infringe on the rights of others, and puts the State's water resources to the most beneficial use.

An applicant, permittee, or licensee who wishes to change the point of diversion, place of use, or purpose of use from that specified in an existing permit or license must petition SWRCB to amend a water right. When considering a petition for a water right amendment, SWRCB considers the same factors as those it considers when a water user applies for a new permit, such as waste prevention, water conservation, infringement on the rights of others, and public trust values.

California Pesticide Regulatory Program

The DPR regulates the sale and use of pesticides in California. DPR is responsible for reviewing the toxic effects of pesticide formulations and determining whether a pesticide is suitable for use in California through a registration process. Although DPR cannot require manufacturers to make changes in labels, it can refuse to register products in California unless manufacturers address unmitigated hazards by amending the pesticide label. Consequently, many pesticide labels that are already approved by EPA also contain California-specific requirements. Pesticide labels are legal requirements and include instructions telling users how to make sure the product is applied only to target pests including precautions the applicator should take to protect human health and the environment. For example, product labels may contain such measures as restrictions in certain land uses and weather (i.e., wind speed) parameters. DPR is also responsible for examining and licensing qualified applicators, aircraft pilots, pest control dealer

designated agents, and agricultural pest control advisers; and for certifying pesticide applicators who use or supervise the use of restricted pesticides.

14.2.3 Regional and Local

Irrigated Lands Regulatory Program

The Irrigated Lands Regulatory Program was initiated in 2003 to prevent agricultural runoff from impairing surface waters. Irrigated lands are lands where water is applied for producing crops, including row, field, and tree crops, as well as commercial nurseries, nursery stock production, managed wetlands, and rice production. Except where the Central Valley RWQCB has adopted geographically-based or commonly based waste discharge requirements, irrigated agriculture lands enrolled in a coalition group are subject to a conditional waiver.

New waste discharge requirements are being developed under the Long-term Irrigated Lands Regulatory Program that address irrigated agricultural discharges throughout the Central Valley. The Central Valley RWQCB adopted Order No. R5-2012-0116 for the Eastern San Joaquin River Watershed and developed draft requirements for the Western San Joaquin River Watershed as part of the Long-term Irrigated Lands Regulatory Program.

Pesticide Use Permits

In addition to Federal and State oversight, County Agricultural Commissioners in California also regulate the sale and use of pesticides and issue use permits for applications of pesticides that are deemed as restricted materials by DPR. County Agricultural Commissioners also collect pesticide use reports and investigate incidents and illnesses.

Fresno County General Plan

The Fresno County General Plan (2000) contains numerous policies to protect and enhance the surface water and groundwater resources in the county. Policies OS-A.1 through OS-A.30 address broad water planning issues, groundwater recharge, the relationship of land use decisions to water issues, and water quality problems. Policies PF-E.1 through PF-E.22 seek to provide efficient, cost-effective, and environmentally-sound storm drainage and flood control facilities that protect both life and property and to divert and retain stormwater runoff for groundwater replenishment.

Fresno County Grading Ordinance

The Fresno County Code includes a grading ordinance that sets forth regulations for control of excavating, grading, earthwork construction, including fills or embankments and related work.

Madera County General Plan

The Madera County General Plan (adopted October 24, 1995) also contains policies related to water resources. These policies address protection of percolation and ground-water recharge, control of sedimentation and excessive grading, avoidance of flood hazards, use of construction BMPs, and storm drainage and flood control (reference, for

example: Policies 5.C.1 through 5.C.4, 5.C.7; Policies 3.E.1 through 3.E.6; and Policies 6.B.1 through 6.B.6).

Madera County Grading and Erosion Control

The Madera County Code includes a chapter on grading and erosion control that sets forth regulations for control of erosion, sedimentation, and other environmental damage resulting from excavations and related activities.

14.3 Environmental Consequences and Mitigation Measures

14.3.1 Impact Assessment Methodology

This section describes the approach for the analysis of surface water resources in the Project area, including geomorphology and water quality. Potential impacts to surface water diversions are evaluated and discussed in Chapter 23.0, "Utilities and Service Systems."

Geomorphology

The specific aspects of the Project that could affect the geomorphology of Reach 2B include the following:

- Changes in the discharge regime associated with the passage of Restoration Flows that significantly exceed pre-Restoration Flows, and the associated effect on both the sediment supply and in-channel energy to transport the sediment and erode the channel banks.
- Changes in sediment transport capacity due to changes in the channel hydraulics at any particular discharge due to changes in channel profile and cross-sectional shape that could affect the vertical and lateral stability of the main channel.
- Changes in water-surface profiles at the upstream end of Reach 2B that could affect bed material supply to the reach, and thus, the sediment balance (and aggradation/degradation tendencies) in the reach. These changes could also impact channel stability in the lower end of Reach 2A.
- Temporary increases in sediment supply to the downstream reaches due to increased erosion in Reach 2B as the channel adjusts to the higher Restoration Flows. This is particularly relevant to the alternatives that include Fresno Slough Dam, where the channel would downcut (or must be excavated to equilibrium grade) between Mendota Dam and San Mateo Avenue due to the base water surface level lowering associated with removal of the boards at Mendota Dam.
- Long-term increases in sediment supply to the downstream reaches due to the passage of higher Restoration Flows through Reach 2B.
- Changes in riparian vegetation caused by changes in the sustained flow under Restoration conditions in the upstream portion of Reach 2B and changes in the sustained water-surface elevations in the downstream portions of the reach. These changes could potentially impact in-channel capacity through changes in the overall hydraulic roughness and associated in-channel hydraulics, the overall

sediment transport capacity and sediment balance through the reach, the tendency for lateral erosion, and flood-carrying capacity.

- Increases in the magnitude and duration of overbank inundation associated with the higher Restoration Flows, removal of internal levees, and other overbank grading activities.

Numerous studies relating to the hydraulics, sediment transport and channel dynamics in Reach 2B for the various Project alternatives have previously been conducted (Mussetter Engineering, Inc. 2002, Tetra Tech 2011, Reclamation 2011). As a result, no new modeling studies were performed for this Environmental Impact Statement/Report; the impact analysis was performed by comparing quantitative estimates of the above factors based on results for the No-Action Alternative, four action alternatives, and existing conditions.

Water Quality

The evaluation of potential impacts to water quality due to the Project was primarily based on a comparison between existing, No-Action, and projected water quality and water quality objectives.

The Project would have the greatest potential to affect turbidity and constituents in sediment suspended by the Project. The Project could potentially generate suspended sediment loads to the river during construction and post-construction. These sediments may contain metals, pesticides, and other priority pollutants. Although the post-construction Reach 2B is expected to be primarily depositional, some alternatives may release suspended sediment related to localized erosion or scour as the channel reaches equilibrium.

14.3.2 Significance Criteria

Geomorphology

Specific thresholds for significance were based on criteria in the Environmental Checklist Form in Appendix G of the California Environmental Quality Act (CEQA) Guidelines, as amended, and other criteria as described below. Under National Environmental Policy Act (NEPA) Council on Environmental Quality (CEQ) Regulations, effects must be evaluated in terms of their context and intensity. Specific criteria that were used in assigning significance include the potential for the following:

- Substantially altering the existing drainage pattern of the site or area, including through the alteration of the course of the river, in a manner which would result in substantial erosion or siltation on- or off-site.
- Aggradation or degradation that causes a substantial increase in channel instability.
- Lateral erosion that could damage existing and/or proposed levees.
- Short- and long-term increases in sediment material load that could cause substantial increases in channel instability, loss of flood-carrying capacity, and reduced habitat quality in downstream reaches.

The significance of these potential changes was based on the magnitude of the change over existing conditions. Also considered are the likely effects of those changes on the ability of each alternative to meet restoration goals while continuing to meet flood-control and other public safety needs.

Water Quality

The thresholds of significance for impacts are based on the Environmental Checklist Form in Appendix G of the State CEQA Guidelines, as amended. Under NEPA CEQ Regulations, effects must be evaluated in terms of their context and intensity. These factors are considered when applying State CEQA Guidelines Appendix G. The Project would result in a significant impact on surface water resources and water quality if the Project would:

- Violate any water quality standards or waste discharge requirements.
- Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff.
- Increases in suspended-sediment loads that could have a substantial adverse effect on downstream water quality.
- Otherwise substantially degrade water quality.

14.3.3 Impacts and Mitigation Measures

This section provides an evaluation of direct and indirect effects of the Project alternatives on surface water resources. It includes analyses of potential effects relative to No-Action conditions in accordance with NEPA and potential effects compared to existing conditions to meet CEQA requirements. Existing conditions for surface water resources assessment is defined as the beginning of Interim Flows in water year 2010, rather than July 2009 when the Notice of Preparation was released because of the wealth of data collected under the Interim Flows component of the SJRRP. The physical changes associated with Project alternatives are then identified as separate from the recent Interim Flows conditions. The analysis is organized by Project alternative with specific impact topics numbered sequentially under each alternative. With respect to surface water, the environmental impact issues and concerns are:

Geomorphology

1. Substantially Altering the Existing Drainage Pattern, Including Alteration of the Course of the River, in a Manner which would Result in Substantial On- or Off-Site Erosion.
2. Increased Aggradation or Degradation that Causes a Substantial Increase in Channel Instability within Reach 2B.
3. Increases in Lateral Erosion that Could Damage Existing and/or Proposed Levees or Other Infrastructure within Reach 2B.
4. Short- and Long-Term Increases in Sediment Load that Could Cause Substantial Increases in Channel Instability in Downstream Reaches.

Water Quality

1. Construction-Related Effects on Water Quality.
2. Long-Term Effects on Water Quality from Mobilization of Mendota Pool Sediments.
3. Long-Term Effects on Water Quality from Floodplain Inundation of Prior Agricultural Soils.
4. Long-Term Effects on Water Quality from Agricultural Practices within the New Floodplain.

Other surface water-related issues covered in the PEIS/R are not covered here because they are programmatic in nature and/or are not relevant to the Reach 2B Mendota Pool Bypass Project area. These include beneficial long-term effects on instream surface water quality resulting from increases in releases of high-quality water from Friant Dam.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. However, other proposed actions under the SJRRP would be implemented, including habitat restoration in other reaches, augmentation of river flows, and reintroduction of salmon. Without the Project in Reach 2B, however, the terms of the Settlement would not be met. This section describes impacts of the No-Action Alternative. The analysis is a comparison to existing conditions and no mitigation is required for No-Action.

The No-Action Alternative would maintain existing levee alignments and heights, and maximum conveyance would continue to be limited to the existing channel capacity. The Chowchilla Bypass would continue to bypass flood flows that exceed the capacity of Reach 2B.

Geomorphology

Impact GEM-1 (No-Action Alternative): ***Substantially Altering the Existing Drainage Pattern, Including Alteration of the Course of the River, in a Manner which Would Result in Substantial On- or Off-Site Erosion***. Under the No-Action Alternative, none of the facilities that are part of the Project would be constructed, and there would not be a change from existing conditions in levee alignments. As a result, there would be no physical changes to the existing drainage patterns within the reach, and there would be **no impact** to channel geomorphology.

Impact GEM-2 (No-Action Alternative): ***Increased Aggradation or Degradation that Causes a Substantial Increase in Channel Instability within Reach 2B.*** Previous sediment transport analyses by Tetra Tech (2011) and sediment transport modeling by Reclamation (2011) indicate that Reach 2B is slightly aggradational under conditions associated with the No-Action Alternative and existing conditions. Because long-term sediment deposition rates would be similar, there would be **no impact** to aggradation or degradation trends in the reach.

Impact GEM-3 (No-Action Alternative): ***Increases in Lateral Erosion that Could Damage Existing and/or Proposed Levees or Other Infrastructure within Reach 2B***. Future lateral erosion in Reach 2B will depend on the magnitude and duration of the flows, the characteristics of the bank material, and the amount and characteristics of the riparian vegetation. Lateral adjustment could occur under the No-Action Alternative as the channel adjusts to the increased magnitude and duration of flows. As discussed in Section 14.1.3, the planform alignment of Reach 2B has not changed substantially since at least the early part of the 20th century, and more likely, since the mid-1800s. Prior to construction of Friant Dam in the early- to mid-1940s, much higher flows regularly passed through Reach 2B than during either the recent historical period (i.e., prior to the Interim Flows program) or during the Interim Flows period. Based on these historical observations and the likelihood that the higher sustained flows would result in more riparian vegetation that tends to stabilize the channel banks, substantial lateral erosion is not anticipated under the No-Action Alternative. The impact to lateral erosion would be **less than significant**.

Impact GEM-4 (No-Action Alternative): ***Short- and Long-Term Increases in Sediment Load that Could Cause Substantial Increases in Channel Instability in Downstream Reaches***. Sediment transport analyses by Tetra Tech (2011) and sediment transport modeling by Reclamation (2011) indicate similar conditions associated with the No-Action Alternative and existing conditions. Sand inputs from Reach 2A would likely result in net deposition in the upper segment of Reach 2B and potentially down to the Mendota Pool, but Reach 3 would be subject to net erosion because Mendota Pool serves as a sediment trap for at least the sand and coarser portion of the sediment load passing through Reach 2B. Because sediment loads to Reach 3 and other downstream reaches would not substantially change, there would be a **less-than-significant** impact to downstream reaches.

Surface Water Quality

Impact SWQ-1 (No-Action Alternative): ***Construction-Related Effects on Water Quality.*** Under the No-Action Alternative, the Project would not be implemented and there would be no construction activities in the Project area. As a result, there would be **no impact** on water quality.

Impact SWQ-2 (No-Action Alternative): ***Long-Term Effects on Water Quality from Mobilization of Mendota Pool Sediments.*** Under the No-Action Alternative, the Project would not be implemented and operations of Mendota Dam would remain unmodified. Mendota Pool could expose potentially-contaminated sediments to Restoration Flows and downstream conveyance; however sediment transport to Reach 3 would be minimized by the obstruction of Mendota Dam. As a result, there would be a **less-than-significant** impact on water quality.

Impact SWQ-3 (No-Action Alternative): ***Long-Term Effects on Water Quality from Floodplain Inundation of Prior Agricultural Soils.*** Under the No-Action Alternative, the Project would not be implemented and the floodplain would not be widened. Compared to existing conditions, there would be no changes in long-term water quality in

the Project area due to exposure of new floodplain area to river flow. As a result, there would be **no impact** on water quality.

Impact SWQ-4 (No-Action Alternative): ***Long-Term Effects on Water Quality from Agricultural Practices within the New Floodplain.*** Under the No-Action Alternative, the Project would not be implemented and the floodplain would not be widened. Compared to existing conditions, there would be no changes in long-term water quality in the Project area due to agricultural practices in new floodplain areas. As a result, there would be **no impact** on water quality.

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

Alternative A would entail construction of new Project facilities, including new levees to establish an approximately 3,000-foot-wide floodplain capable of safely conveying up to 4,500 cfs through the reach with 3 feet of freeboard. The Compact Bypass channel and levee system would be constructed to the north/east of the existing river channel to bypass Restoration Flows around Mendota Pool. Other key features include construction of a fish barrier below Mendota Dam, the Mendota Pool Dike (separating the San Joaquin River and Mendota Pool), and the South Canal and South Canal bifurcation structure, located near the upstream end of the reach, to deliver up to 2,500 cfs to Mendota Pool. The San Joaquin River control structure of the Chowchilla Bifurcation Structure would be removed, and the new South Canal bifurcation structure would be used to divert flood flows into the Chowchilla Bypass. The San Mateo Avenue crossing would be modified. No construction activities are proposed at or near Mendota Dam, which falls outside the Project boundary under Alternative A. Agricultural practices (e.g., annual crops, pasture, or floodplain-compatible permanent crops) would be allowed in the newly-created floodplain. Construction activity is expected to occur intermittently over an approximate 132-month timeframe.

Geomorphology

Impact GEM-1 (Alternative A): ***Substantially Altering the Existing Drainage Pattern, Including Alteration of the Course of the River, in a Manner which Would Result in Substantial On- or Off-Site Erosion***. Compared to the No-Action Alternative, the course of the river within the footprint of Alternative A upstream from the Compact Bypass channel would not be directly changed by the Project. The Compact Bypass channel would, however, direct flows to the north around Mendota Pool. The Compact Bypass channel would be designed as an unlined earthen channel, would be approximately 5,300 feet long with a total corridor width of approximately 950 feet. Vegetated revetment would be included along both channel banks within the portion of the bypass containing the grade control structures to provide additional protection against flanking. Revetment would likely consist of buried riprap covered with topsoil, erosion control fabric, and native woody vegetation (see Section 2.2.5). Revetment would prevent substantial on-site erosion; thus, this change would not result in substantial on- or off-site erosion.

Under this alternative, the channel would be re-connected to the floodplain within the levees, changing the overbank drainage patterns compared to the No-Action Alternative. This would provide a beneficial effect to channel geomorphology by limiting the in-

channel energy and erosion potential at flows above bankfull and providing a sediment source to build and rejuvenate the floodplain.

In addition to its primary purpose of diverting flows into the South Canal, the South Canal bifurcation structure would also serve as a grade-control structure that would effectively fix the bed of the river at, and immediately upstream from, the structure, preventing channel downcutting in the upstream portion of Reach 2B that could result from downstream changes. Depending on the specific design, a local scour hole could develop on the downstream side of the structure that would cause a temporary increase in on-site erosion, particularly at high flows. However, protection measures would be incorporated into the structure to limit the adverse effects of this scour hole. Stone slope protection (riprap) would be provided on the upstream and downstream slopes of control structure embankments including some portions of the side slopes of the channel itself to prevent or minimize scouring. Riprap would be placed on bedding over geotextile fabric (see Section 2.2.5).

When comparing Alternative A to existing conditions, impacts to the existing drainage pattern would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). Because Project design would prevent substantial on-site erosion and because new structures would limit in-channel energy and erosion potential, this impact is considered to be **less than significant.**

Impact GEM-2 (Alternative A): ***Increased Aggradation or Degradation that Causes a Substantial Increase in Channel Instability within Reach 2B.*** Compared to the No-Action Alternative, construction of the new levees and the Compact Bypass channel would allow up to 4,500 cfs of Restoration Flows to be carried through the reach. As a result, there would be a substantial increase in the magnitude and duration of flows and an associated increase in both the amount of sediment delivered to the reach from upstream and the amount of sediment that actually moves through the reach.

Compared to existing conditions, Alternative A would result in similar impacts as described in the preceding paragraph (i.e., the comparison of Alternative A to the No-Action Alternative). The previously discussed sediment transport analyses by Tetra Tech (2011) and sediment-transport modeling by Reclamation (2011) indicate that Reach 2B is slightly aggradational under existing conditions, and this aggradational tendency would increase by a small amount (approximately 10 percent) for this alternative, in part due to reconnection of the channel with the floodplain and the associated effect of limiting in-channel energy and sediment transport capacity. Based on these studies, the aggradation does not appear to be sufficient to cause a substantial increase in channel instability; this impact would be **less than significant**.

Impact GEM-3 (Alternative A): ***Increases in Lateral Erosion that Could Damage Existing and/or Proposed Levees or Other Infrastructure within Reach 2B***. Compared to the No-Action Alternative, the duration of flows up to the existing capacity of Reach 2B would not change. However, with construction of the new levees and Compact Bypass channel under this alternative, flows up to 4,500 cfs would pass through the

reach; thus, there would be more energy available to drive lateral erosion. To protect levees from erosion, a 300-foot buffer between the river channel and levees would be provided. If the buffer cannot be provided along river bends or at structures, erosion protection such as revetment, bioengineering, or other erosion protection techniques would be implemented to prevent or minimize erosion (see Section 2.2.4).

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative A to the No-Action Alternative). Considering the historical lack of lateral erosion, even under the much higher flows during the pre-Friant Dam period and the likelihood that additional riparian vegetation that would tend to protect against bank erosion would establish along the reach, the inclusion of erosion protection offsets the potential for increases in lateral erosion. The impact on geomorphology would be **less than significant**.

Impact GEM-4 (Alternative A): ***Short- and Long-Term Increases in Sediment Load that Could Cause Substantial Increases in Channel Instability in Downstream Reaches***. Under Alternative A, Restoration Flows of up to 4,500 cfs would pass through Reach 2B and the Compact Bypass channel into Reach 3. Sediment transport analyses by Tetra Tech (2011) and sediment transport modeling by Reclamation (2011) indicates that this would cause a substantial increase in the sediment load to Reach 3, as compared to the No-Action Alternative, both due to the increase in flow conveyance capacity of Reach 2B and due to elimination of the buffering effect of Mendota Pool. Since the flows in Reaches 3 and 4A would be more frequently in the upper range of their capacities under Alternative A, the capacity of those reaches to transport the higher sediment supply would also increase. Estimates of the sediment transport balance in Reach 3 indicate that the reach would be in approximate sediment transport balance under this alternative; thus, there should not be substantial increases in downstream channel instability.

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative A to the No-Action Alternative). The impact would be **less than significant**.

Surface Water Quality

Impact SWQ-1 (Alternative A): ***Construction-Related Effects on Water Quality.*** Compared to the No-Action Alternative, Alternative A would result in temporary adverse impacts to surface water quality due to the release of sediments and other contaminants during construction activities (without incorporation of appropriate best management practices or BMPs as mitigation described below). Construction activity is expected to occur intermittently over approximately 8.5 to 11 years. Construction activities, including grading, vegetation removal, excavation, trenching, and backfilling, have the potential to affect surface water quality, if not properly controlled. These activities could result in disturbed soils being temporarily exposed to the erosive forces of wind, rain, and stormwater runoff, which could result in the release of sediment into nearby water bodies, drainage ditches and the San Joaquin River. In addition to the release of sediment, contamination of stormwater runoff with typical chemicals used during construction such as fuels, oils, lead solder, solvents, and glues could occur through the daily use, transportation, and storage of these materials, if not properly controlled.

Flow in the San Joaquin River and operation of the existing Columbia Canal would be maintained during construction; therefore, construction of control structures in the river channel would require installation of removable cofferdams and temporary diversion of flows around the work area (see Construction Considerations in Section 2.2.4). Conveyance of sediment and other pollutants from construction areas to receiving waters could occur directly during in-water work or by direct overland flow.

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). This impact is considered to be **potentially significant.**

Mitigation Measure SWQ-1 (Alternative A): ***Development and Implementation of SWPPP.*** A SWPPP consistent with the Statewide NPDES Construction General Permit (Order No. 2009-0009-DWQ, as amended) will be developed and implemented. The SWPPP will detail the construction-phase erosion and sediment control BMPs and the housekeeping measures for control of contaminants other than sediment, as well as the treatment measures and BMPs to be implemented for control of pollutants once the Project has been constructed. Erosion control BMPs will include source control measures such as scheduling of construction activities with regard to the rainy season, wetting of dry and dusty surfaces to prevent fugitive dust emissions, preservation of existing vegetation, and effective soil cover (e.g., geotextiles, straw much, hydroseeding) for inactive areas and finished slopes to prevent sediments from being dislodged by wind, rain, or flowing water. Sediment control BMPs will include measures such as street sweeping transportation corridors, and installation of fiber rolls and sediment basins to capture and remove particles that have already been dislodged. The SWPPP will establish good housekeeping measures such as construction vehicle storage and maintenance, handling procedures for hazardous materials, and waste management BMPs. These BMPs include procedural and structural measures to prevent release of wastes and materials used at the site. BMPs associated with installation of removable cofferdams and temporary diversion of flows around the work area will be described. The SWPPP will also describe post-construction BMPs to be implemented for control of pollutants once the Project has been constructed.

Implementation of the SWPPP would avoid or mitigate runoff pollutants at the construction sites to the "maximum extent practicable." (See also Chapter 13.0, "Hydrology – Groundwater," which addresses impacts to groundwater and Chapter 19.0, "Public Health and Hazardous Materials," which addresses impacts from release of hazardous materials during construction.) The impact would be **less than significant** after mitigation.

> **Implementation Action**: Project proponents and/or the construction contractor will prepare and implement an SWPPP consistent with requirements in the Statewide NPDES Construction General Permit. The SWPPP will set forth a BMP monitoring, maintenance, and reporting schedule and will identify the responsible entities during the construction and post-construction phases. Monitoring will include visual inspections of the BMPs, inspection for non-stormwater discharges, and visual inspection and/or sample collection of stormwater discharges. If

monitoring results indicate that the discharge is above the turbidity Numeric Action Level (NAL) or outside the range of the pH NAL, a construction site and run-on evaluation will be conducted to determine the source of the pollutant and corrective actions will be immediately implemented if necessary.

Location: Project areas with active construction or used by construction personnel, including access roads, staging and storage areas, borrow sites, and areas within the river channel and on adjacent uplands.

Effectiveness Criteria: Performance tracking will be based on successful compliance with the Statewide NPDES Construction General Permit.

Responsible Agency: Reclamation and the construction contractor.

Monitoring/Reporting Action: At a minimum, annual reports will be submitted to the SWRCB via the Storm Water Multiple Application and Report Tracking System.

Timing: The SWPPP will be developed prior to construction and will be implemented during construction.

Impact SWQ-2 (Alternative A): ***Long-Term Effects on Water Quality from Mobilization of Mendota Pool Sediments.*** Contaminants have been found in sediment accumulated in Mendota Pool above sediment quality thresholds including metals and persistent organic pollutants (i.e., arsenic, chromium, copper, nickel, 4,4'-DDD, and 4,4'-DDE). Concentrations of several constituents in elutriate derived from Mendota Pool sediments exceed water quality objectives (see Section 14.1.4). Contaminates were found to be uniformly distributed throughout Mendota Pool downstream of RM 205.5 with concentrations decreasing to insignificant levels above RM 207 (SJRRP 2012).

Compared to the No-Action Alternative, implementation of Alternative A could expose potentially-contaminated in-stream sediments to Restoration Flows and downstream conveyance. Alternative A includes construction of the Compact Bypass channel. The bypass channel would connect to Reach 2B approximately 0.9 mile upstream of Mendota Dam (approximately RM 205.5), bypass Mendota Pool to the north, and connect to Reach 3 approximately 0.6 mile downstream of Mendota Dam (approximately RM 204). The total elevation drop in the bypass channel would be approximately 12 feet (see Section 2.2.5). Grade-control structures would be included within the bypass channel to achieve the necessary elevation change between Reach 2B and Reach 3. The elevation of the upstream end of the bypass channel (which would be determined by the highest grade control structure in Alternative A) would influence erosion potential in the lower portion of Reach 2B. If the bypass channel is below existing grades, channel downcutting would occur. The increased erosion would be temporary as the channel adjusts to the new profile and Restoration Flow regime. Floodplain and channel grading could be used to establish a new equilibrium channel slope or to create more desirable sediment transport conditions to minimize erosion. Although there may be short-term erosion of potentially-contaminated sediments in areas upstream of the bypass channel (i.e., in the existing San

Joaquin River arm of Mendota Pool), the bypass would avoid the portions of Mendota Pool with the highest concentrations of contaminates and channel downcutting would be minimized by grade controls in the bypass channel. Transient increases in water quality contaminates would likely be diluted by increased flows to below water quality objectives.

Alternative A would not modify Mendota Dam or permanently lower Mendota Pool. Operations of Mendota Dam would be similar to operations under the No-Action Alternative (i.e., flashboards would be removed periodically for maintenance or flood flows).

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). The impact would be **less than significant**.

Impact SWQ-3 (Alternative A): ***Long-Term Effects on Water Quality from Floodplain Inundation of Prior Agricultural Soils.*** Compared to the No-Action Alternative, Restoration Flows under Alternative A could be exposed to soils containing metals, pesticides, and other priority pollutants on the new floodplain area. Portions of the existing levees would be removed and new levees would be constructed and set back from the river to form a narrow floodplain averaging approximately 3,000 feet wide. Land that is currently outside of the existing levees would be subject to periodic inundation by Restoration Flows. The area within the new Compact Bypass channel would also be subject to inundation.

Most of these areas are currently in agricultural production and have been for many years. Areas currently in agricultural production have been regularly irrigated and so potential surface contaminates that leach are likely to no longer be in the surface layer in even moderate concentrations. Other potential surface contaminants, such as legacy pesticides, bind tightly to soil organics, are relatively immobile in soil, and have a low tendency to leach.

Soil chemistry data are not available for areas currently in agricultural production; however, it is possible that the soils contain trace concentrations of herbicides and pesticides that are currently or were historically used in farming practices, including persistent organic pollutants such as DDT, its breakdown products (e.g., DDE), and dieldrin. Although DDT and dieldrin were banned for use in agriculture in the 1970s, they bind tightly to soils, are extremely persistent in the environment, highly toxic to many aquatic invertebrate species, and tend to biomagnify in the food chain. The reported half-life of DDT in soil is 2 to 15 years and the half-life of dieldrin in soil is 5 years. Newer pesticides are less likely to persist in soils or water. These persistent organic pollutants have been found in Mendota Pool sediments (SJRRP 2012) which suggests that they were historically used in the vicinity or have been influenced by inputs from the DMC. If persistent organic pollutants or other potential pollutants are present in soils on the floodplain or in the Compact Bypass channel, soil erosion could affect water quality in downstream reaches. Erosion protection such as revetment, bioengineering, or other erosion protection techniques would be implemented near levees and grade control

structures to protect the Compact Bypass from excess erosion. Other engineered structures would also be protected (see Section 2.2.5). In addition, once a vegetative cover is established, erosion on the floodplain would be reduced. Soil erosion is most likely to occur during flood flows, which would also provide dilution.

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). The impact would be **potentially significant**.

Mitigation Measure SWQ-3 (Alternative A): ***Minimize Use of Pesticide and Herbicide Contaminated Soil.*** Refer to Mitigation Measure HAZ-4 (Alternative A). A similar mitigation measure would be used here. Construction activities in the Project area will be modified to minimize use of contaminated soil. Implementation of this mitigation measure would reduce this impact to a **less than significant** level.

> **Implementation Action:** The contractor will collect soil samples in conformance with EPA SW-846 methodology and analyze the samples for heavy metals and chlorinated pesticides and herbicides. The analytical results will be evaluated against EPA's Regional Screening Levels (2012), guidelines for freshwater disposal of dredge materials, aquatic toxicity screening levels, or other regulatory and literature guidance documents for aquatic toxicity. Alternatively, aquatic testing may be conducted on representative soil samples for this purpose. If the soil pesticide and herbicide conglomerate toxicity factors and/or toxicity testing shows unacceptable toxicity levels, that soil will not be used in the construction of Project levees and concentrated areas of contamination would be remediated in areas where the soil will come in direct contact with the San Joaquin River water.
>
> **Location:** Floodplain areas or areas used for borrow materials.
>
> **Effectiveness Criteria:** Effectiveness will be based on compliance with testing and risk assessment guidelines.
>
> **Responsible Agency:** Reclamation and the construction contractor.
>
> **Monitoring/Reporting Action:** Adequacy of the proposed construction practices will be confirmed with Reclamation managers and California State Lands Commission monitors.
>
> **Timing:** Prior to construction of Project levees or floodplain grading.

Impact SWQ-4 (Alternative A): ***Long-Term Effects on Water Quality from Agricultural Practices within the New Floodplain.*** Compared to the No-Action Alternative, Alternative A would increase the amount of direct runoff from agricultural land uses to Reach 2B. Between the main river channel banks and the proposed levees, agricultural practices (e.g., annual crops, pasture, or floodplain-compatible permanent crops) would occur.

The use of herbicides and pesticides are regulated by DPR. Requirements for the use of these materials, such as avoidance and minimization measures and BMPs, are printed on the manufacture's labels. Only certain herbicides or pesticides can be used near waterways or in areas that could be inundated and these compounds must be applied consistent with DPR regulations. If herbicides or pesticides are used on agricultural lands within the floodplain area, they would be applied by DPR licensed or certified applicators according to label requirements. Application would not occur when weather parameters exceed label specifications (for example, when wind exceeds specified speed) or when precipitation occurs or is forecasted with a specified period to prevent pesticides from entering the water through surface runoff. Applications would adhere to label directions for application rates.

Cattle could continue to have direct access to the river in some areas and would be a direct source of nutrients. The cattle may also damage riparian vegetation and expose soils to erosion. Fields in the new floodplain could be drained by ditches that convey agricultural return flows and runoff to the river. Flow in the ditches would contain nutrients and pesticides used in agricultural practices. There may be increased loadings of nutrients and agricultural chemicals to the San Joaquin River; however, agricultural practices would comply with the Irrigated Lands Regulatory Program, and increased flow rates would likely dilute these pollutants to below water quality objectives.

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to No-Action Alternative). Therefore, the impact would be **less than significant**.

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Alternative B would entail construction of new Project facilities, including new levees to establish an approximately 4,200-foot-wide floodplain capable of safely conveying up to 4,500 cfs through the reach with 3 feet of freeboard. The Compact Bypass channel and levee system would be constructed to the northeast of the existing river channel to bypass Restoration Flows around Mendota Pool. Other key features include construction of the Compact Bypass Bifurcation Structure, which would allow up to 2,500 cfs to be conveyed from Reach 2B into Mendota Pool, and construction of a fish passage structure for the Compact Bypass Control Structure. Flow would continue to enter at the upstream end of Reach 2B through the existing San Joaquin River control structure of the Chowchilla Bifurcation Structure. A fish passage facility would be added to the structure. The San Mateo Avenue crossing would be removed. No construction activities are proposed at or near Mendota Dam, which falls outside the Project boundary under Alternative B. The new floodplain would be selectively planted following construction with native vegetation and managed for non-native plant species. Construction activity is expected to occur intermittently over an approximate 157-month timeframe.

Geomorphology

Impact GEM-1 (Alternative B): *Substantially Altering the Existing Drainage Pattern, Including Alteration of the Course of the River, in a Manner which Would Result in Substantial On- or Off-Site Erosion*. Compared to the No-Action Alternative, effects on

the existing drainage pattern under Alternative B would be the same as those described for Alternative A. Refer to Impact GEM-1 (Alternative A). This impact would be **less than significant.**

Impact GEM-2 (Alternative B): ***Increased Aggradation or Degradation that Causes a Substantial Increase in Channel Instability within Reach 2B.*** Compared to the No-Action Alternative, construction of the new levees and the Compact Bypass channel would allow up to 4,500 cfs of Restoration Flows to be carried through the reach. As a result, there would be a substantial increase in the magnitude and duration of flows and an associated increase in both the amount of sediment delivered to the reach from upstream and the amount of sediment that actually moves through the reach. There would also be an increase in the amount of material removed from the Reach 2B channel by river flows because the Compact Bypass channel in Alternative B would be designed to prevent long-term undesirable bed erosion or deposition problems in Reach 2B and the adjacent Reaches 2A and 3, especially at structures. The Compact Bypass design in Alternative B includes fewer grade control structures than the other alternatives, which would initiate channel bed erosion in Reach 2B to remove sediment that has been deposited in the San Joaquin River arm of Mendota Pool. This channel bed erosion is anticipated to be up to 7 to 8 feet deep near the upstream end of the Compact Bypass and gradually decrease to zero erosion approximately 4 miles further upstream (RM 210). The channel bed erosion in Reach 2B would result in sediment deposition in the Reach 3 channel. The Reach 3 deposition is anticipated to be up to 7 feet thick near the downstream end of the bypass and gradually decrease to zero deposition approximately 1 mile downstream (RM 203). These changes in the bed profile are expected to occur over the first 6 to 15 years post-construction depending on flows. The amount of degradation in Reach 2B and resulting aggradation in Reach 3 would be controlled by the Compact Bypass bifurcation structure as well as grade control structures in the bypass channel.

Compared to existing conditions, Alternative B would result in similar impacts as described in the preceding paragraph (i.e., the comparison of Alternative B to the No-Action Alternative). The previously discussed sediment transport analyses by Tetra Tech (2011) and sediment-transport modeling by Reclamation (2011) indicate that Reach 2B is slightly aggradational under existing conditions, and this aggradational tendency would decrease and become erosional in portions of Reach 2B for this alternative, due to design intent of the Compact Bypass. The degradation would be controlled by the Compact Bypass bifurcation structure as well as grade control structures in the bypass channel and does not appear to be sufficient to cause a substantial increase in channel instability; this impact would be **less than significant**.

Impact GEM-3 (Alternative B): ***Increases in Lateral Erosion that Could Damage Existing and/or Proposed Levees or Other Infrastructure within Reach 2B.*** Compared to the No-Action Alternative, the duration of flows up to the existing capacity of Reach 2B would not change. However, with construction of the new levees and Compact Bypass channel under this alternative, flows up to 4,500 cfs would pass through the reach; thus, there would be more energy available to drive lateral erosion. The degradation in Reach 2B and aggradation in Reach 3 (discussed above in Impact GEM-2 (Alternative B)) could induce some bank erosion adjacent to these areas, but the Project

design would include riparian vegetation, rock vanes, woody materials, or revetment to protect against bank erosion in susceptible areas. In addition, the neck of the first meander bend downstream from the Chowchilla Bifurcation Structure is only about one channel width wide (approximately 280 feet). Although this area has not eroded significantly during the period of available photography, the bend could cut off very rapidly if lateral erosion does occur at this location. This would not endanger the levees in the reach, but it would steepen the local channel gradient, which could cause bed lowering on the downstream side of the Chowchilla Bifurcation Structure. To protect levees from erosion, a 300-foot buffer between the river channel and levees would be provided. If the buffer cannot be provided along river bends or at structures, erosion protection such as revetment, bioengineering, or other erosion protection techniques would be implemented to prevent or minimize erosion (see Section 2.2.4).

When comparing Alternative B to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative B to the No-Action Alternative). Considering the historical lack of lateral erosion, even under the much higher flows during the pre-Friant Dam period and the likelihood that additional riparian vegetation that would tend to protect against bank erosion would establish along the reach, the inclusion of erosion protection offsets the potential for increases in lateral erosion. The impact on geomorphology would be **less than significant**.

Impact GEM-4 (Alternative B): ***Short- and Long-Term Increases in Sediment Load that Could Cause Substantial Increases in Channel Instability in Downstream Reaches***. Under Alternative B, Restoration Flows of up to 4,500 cfs would pass through Reach 2B and the Compact Bypass channel into Reach 3. Sediment transport analyses by Tetra Tech (2011) and sediment transport modeling by Reclamation (2011) indicates that this would cause a substantial increase in the sediment load to Reach 3, as compared to the No-Action Alternative, both due to the increase in flow conveyance capacity of Reach 2B and due to elimination of the buffering effect of Mendota Pool. There would also be an increase in the amount of material removed from the Reach 2B channel by river flows because the Compact Bypass channel in Alternative B would be designed to prevent long-term undesirable bed erosion or deposition problems in Reach 2B and the adjacent Reaches 2A and 3, especially at structures (see discussion above in Impact GEM-2 (Alternative B)). Since the flows in Reaches 3 and 4A would be more frequently in the upper range of their capacities under Alternative B due to the increased capacity in Reach 2B, the capacity of those reaches to transport the higher sediment supply would also increase. Estimates of the sediment transport balance in Reach 3 indicate that the reach would range from being in approximate sediment transport balance to slightly aggradational in the short term and slightly degradational over the long term under this alternative; thus, there should not be substantial increases in downstream channel instability.

When comparing Alternative B to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative B to the No-Action Alternative). The impact would be **less than significant**.

Surface Water Quality

Impact SWQ-1 (Alternative B): *Construction-Related Effects on Water Quality.* Construction-related effects on water quality under Alternative B would be similar to those described for Alternative A. Refer to SWQ-1 (Alternative A) for details. The primary difference under Alternative B is the longer construction duration of 9 to 13 years. This impact is considered to be a **potentially significant** impact.

Mitigation Measure SWQ-1 (Alternative B): *Development and Implementation of SWPPP.* Refer to Mitigation Measure SWQ-1 (Alternative A). The same measure would be used here. A SWPPP will be developed and implemented which details the construction-phase erosion and sediment control BMPs and the housekeeping measures for control of contaminants other than sediment, as well as the treatment measures and BMPs to be implemented for control of pollutants once the Project has been constructed . This impact would be **less than significant after mitigation**.

Impact SWQ-2 (Alternative B): *Long-Term Effects on Water Quality from Mobilization of Mendota Pool Sediments.* Contaminants have been found in sediment accumulated in Mendota Pool above sediment quality thresholds including metals and persistent organic pollutants (i.e., arsenic, chromium, copper, nickel, 4,4'-DDD, and 4,4'-DDE). Concentrations of several constituents in elutriate derived from Mendota Pool sediments exceed water quality objectives (see Section 14.1.4). Contaminates were found to be uniformly distributed throughout Mendota Pool downstream of RM 205.5 with concentrations decreasing to insignificant levels above RM 207 (SJRRP 2012).

Compared to the No-Action Alternative, implementation of Alternative B could expose potentially-contaminated in-stream sediments to Restoration Flows and downstream conveyance. Alternative B includes construction of the Compact Bypass channel. The bypass channel would connect to Reach 2B approximately 0.9 mile upstream of Mendota Dam (approximately RM 205.5), bypass Mendota Pool to the north, and connect to Reach 3 approximately 0.6 mile downstream of Mendota Dam (approximately RM 204). The total elevation drop in the bypass channel would range approximately from 2 to 7 feet (see Section 2.2.6). Grade-control structures would be included within the bypass channel to achieve the necessary elevation change between Reach 2B and Reach 3. The elevation of the upstream end of the bypass channel (which in Alternative B would be determined by the Compact Bypass river control structure) would influence erosion potential in the lower portion of Reach 2B. The bypass channel would be constructed below existing grades, and channel downcutting in Reach 2B would occur. The increased erosion would be temporary as the channel adjusts to the new profile and Restoration Flow regime. Floodplain and channel grading could be used to establish a new equilibrium channel slope or to create more desirable sediment transport conditions to minimize erosion. Although there may be short-term erosion of potentially-contaminated sediments in areas upstream of the bypass channel (i.e., in the existing San Joaquin River arm of Mendota Pool), the bypass would avoid the portions of Mendota Pool with the highest concentrations of contaminates and amount of channel downcutting would be controlled by the Compact Bypass river control structure and grade control structures in the bypass channel. Transient increases in water quality contaminates would likely be diluted by increased flows to below water quality objectives.

Alternative B would not modify Mendota Dam or permanently lower Mendota Pool. Operations of Mendota Dam would be similar to operations under the No-Action Alternative (i.e., flashboards would be removed periodically for maintenance or flood flows).

When comparing Alternative B to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative B to the No-Action Alternative). The impact would be **less than significant**.

Impact SWQ-3 (Alternative B): *Long-Term Effects on Water Quality from Floodplain Inundation of Prior Agricultural Soils.* Long-term effects on water quality of Restoration Flows within the new floodplain under Alternative B would be similar to those described for Alternative A. Refer to SWQ-3 (Alternative A) for details. The primary difference under Alternative B is that the larger floodplain area could encompass more farmland acreage. This impact would be **potentially significant**.

Mitigation Measure SWQ-3 (Alternative B): *Minimize Use of Pesticide and Herbicide Contaminated Soil.* Refer to Mitigation Measure SWQ-3 (Alternative A). The same measure would be used here. Construction activities in the Project area will be modified to minimize use of contaminated soil. Implementation of this mitigation measure would reduce this impact to a **less than significant** level.

Impact SWQ-4 (Alternative B): *Long-Term Effects on Water Quality from Agricultural Practices within the New Floodplain.* Similar to the effects described for Alternative A, agricultural practices would continue under Alternative B in the proposed floodplain between the main river channel banks and the proposed levees. There may be increased loadings of nutrients and agricultural chemicals to the San Joaquin River; however, agricultural practices would comply with the Irrigated Lands Regulatory Program, and increased flow rates would likely dilute these pollutants to below water quality objectives. Direct impacts of those practices on water quality in the San Joaquin River would be **less than significant**.

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Alternative C would entail construction of new Project facilities, including new levees to establish an approximately 3,000-foot-wide floodplain capable of safely conveying up to 4,500 cfs through the reach with 3 feet of freeboard. A new dam would be constructed across Fresno Slough to contain Mendota Pool so that up to 4,500 cfs of Restoration Flows can be conveyed downstream through the existing river channel and across the existing Mendota Dam sill into Reach 3. A portion of river sediments that have accumulated behind Mendota Dam would be removed and disposed of appropriately. A new Short Canal with a control structure capable of delivering up to 2,500 cfs from the river in Reach 2B to Mendota Pool would be constructed near the new dam. Other key features include construction of fish passage facilities at Mendota Dam, a fish screen on the Short Canal to prevent juvenile fish from entering Mendota Pool, and a fish barrier located just north of Fresno Slough dam to prevent adult fish from migrating into Fresno Slough during Kings River flood releases. The Chowchilla Bifurcation Structure would continue to divert San Joaquin River flows into Chowchilla Bypass during flood

operations. A fish passage facility would be added to the San Joaquin River control structure of the Chowchilla Bifurcation Structure to provide upstream fish passage. The San Mateo Avenue crossing would be modified. The new floodplain would be planted following construction with native vegetation and managed for non-native plant species. Construction activity is expected to occur intermittently over an approximate 133-month timeframe.

Geomorphology

Impact GEM-1 (Alternative C): *Substantially Altering the Existing Drainage Pattern, Including Alteration of the Course of the River, in a Manner which Would Result in Substantial On- or Off-Site Erosion*. Compared to the No-Action Alternative, the course of the river within the footprint of Alternative C would not be changed by the Project. The existing Mendota Dam would be modified to provide run-of-the-river conditions during Restoration Flows, which would lower water-surface elevations and steepen the effective channel gradient through the San Joaquin River arm of Mendota Pool, increasing erosion potential in this area. The concrete sill at the existing dam would, however, remain in-place, providing grade control for the upstream reach and limiting the amount of downcutting that could occur in the upstream channel. The Project would excavate portions of the former pool impoundment area (i.e., the San Joaquin arm of Mendota Pool) to establish a new equilibrium channel slope (see Section 2.2.7) minimizing the amount of sediments being washed downstream when Mendota Dam is lowered. Some additional channel erosion may occur as the channel adjusts to future flows, but this erosion is expected to be relatively minor. Sediment levels in the Fresno Slough arm of Mendota Pool are expected to be similar as the No-Action Alternative because the water surface elevations would be maintained at levels similar to No-Action conditions.

When comparing Alternative C to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative C to No-Action Alternative). As a result, this impact would be **less than significant.**

Impact GEM-2 (Alternative C): *Increased Aggradation or Degradation that Causes a Substantial Increase in Channel Instability within Reach 2B.* Compared to the No-Action Alternative, there would be a substantial increase in the magnitude and duration of high flow events and an associated increase in both the amount of sediment delivered to the reach from upstream and the amount of sediment that actually moves through the reach. In contrast to No-Action Alternative, Alternative C is expected to have increased degradation in the lower portion of the reach. Channel bed degradation and associated increase in bank heights may also cause an increase in bank instability.

Mendota Dam would be modified to provide run-of-the-river conditions, which would lower water-surface elevations and steepen the effective channel gradient through the reach, increasing erosion potential in the San Joaquin River arm of Mendota Pool. However, the Project would excavate portions of the former pool impoundment area (i.e., the San Joaquin arm of Mendota Pool) to establish a new equilibrium channel slope (see Section 2.2.7) minimizing the amount of sediments being washed downstream when Mendota Dam is lowered. Some additional degradation may occur during Restoration

Flows as the upstream channel adjusts to the lowered base-level control resulting from modifications to Mendota Dam.

According to an assessment of the equilibrium channel slope for this alternative, if portions of the former pool impoundment area were not excavated, the bank heights under Alternative C would increase by an average of 3.5 feet in approximately 4.5 miles of the downstream end of Reach 2B, as compared to the No-Action Alternative. Potential channel bed degradation associated with Alternative C would not progress sufficiently far upstream to impact either the new San Mateo Avenue crossing or the Chowchilla Bifurcation Structure.

Although levees and infrastructure within the potential degradation zone could be affected by an increase in bank erosion where they are in close proximity to the channel, a new equilibrium channel slope would be established to minimize channel downcutting (see Section 2.2.7) and appropriate levee protection measures, such as revetment, would be included near proposed structures (see Section 2.2.4). These measures would minimize the risk of channel instability.

When comparing Alternative C to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative C to No-Action Alternative). This impact would be **less than significant**.

Impact GEM-3 (Alternative C): ***Increases in Lateral Erosion that Could Damage Existing and/or Proposed Levees or Other Infrastructure within Reach 2B***. Refer to Impact GEM-2 (Alternative C). The potential for increased bank erosion and bank height under this alternative could lead to increases in lateral erosion that could damage proposed levees and other infrastructure. However, the Project would incorporate erosion protection as described in GEM-3 (Alternative A). As a result, impacts on geomorphology would be **less than significant**.

Impact GEM-4 (Alternative C): ***Short- and Long-Term Increases in Sediment Load that Could Cause Substantial Increases in Channel Instability in Downstream Reaches***. Compared to the No-Action Alternative, Alternative C would increase flow capacity in Reach 2B and, as discussed under Alternatives A and B, the increase in Restoration Flows passing through Reach 2B (i.e., flows between the existing safe channel capacity and the design capacity of 4,500 cfs) would increase sediment loading to the downstream reaches. In addition, Mendota Pool serves as a sediment trap for at least the sand and coarser portion of the sediment load passing through the upstream part of Reach 2B under the No-Action Alternative. Under Alternative C, the flash boards currently used to close the bays at Mendota Dam and back up water would be removed to provide run-of-the-river conditions during Restoration Flows. The modifications to Mendota Dam that would increase the gradient through the San Joaquin River arm of Mendota Pool (e.g., removing the flash boards) would reduce the effectiveness of the sediment trap in Mendota Pool, and sediment that would otherwise have been stored in Mendota Pool would pass directly downstream into Reach 3 causing short-term increases in the downstream sediment load into Reach 3. Sediment from the Fresno Slough arm of

Mendota Pool that would have been trapped behind Mendota Dam under the No-Action Alternative would likely be trapped behind Fresno Slough Dam under Alternative C.

Under the No-Action Alternative, the flash boards at Mendota Dam would have been periodically removed to facilitate maintenance on the structure, during which time some of the sediment trapped in Mendota Pool would be re-entrained and carried downstream into Reach 3, limiting the long-term sediment trapping effects. As a result, substantial increases in the long-term sediment load to downstream reaches (i.e., Reach 3) would be limited under Alternative C, and actually would be closer to a desired condition in which there is continuous sediment continuity through Reach 2B.

When comparing Alternative C to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative C to No-Action Alternative). As a result, this impact would be **less than significant**.

Surface Water Quality

Impact SWQ-1 (Alternative C): ***Construction-Related Effects on Water Quality.*** Construction-related effects on water quality would be the same under Alternative C as those described for Alternative A. Refer to SWQ-1 (Alternative A) for details. The primary difference under Alternative C is the potentially shorter construction duration of 7.5 to 11 years. This impact is considered to be a **potentially-significant** impact.

Mitigation Measure SWQ-1 (Alternative C): ***Development and Implementation of SWPPP.*** Refer to Mitigation Measure SWQ-1 (Alternative A). The same measure would be used here. A SWPPP will be developed and implemented which details the construction-phase erosion and sediment control BMPs and the housekeeping measures for control of contaminants other than sediment, as well as the treatment measures and BMPs to be implemented for control of pollutants once the Project has been constructed. This impact would be **less than significant** after mitigation.

Impact SWQ-2 (Alternative C): ***Long-Term Effects on Water Quality from Mobilization of Mendota Pool Sediments.*** Compared to No-Action Alternative, Mendota Dam would be modified under Alternative C to provide run-of-the-river conditions during Restoration Flows, which would lower water-surface elevations, steepen the effective channel gradient through the San Joaquin River arm of Mendota Pool, and increase the erosion potential in this area. Concentrations of several constituents in elutriate derived from these sediments exceed water quality objectives. Lowering the water surface elevation behind Mendota Dam would expose potentially-contaminated in-stream sediments to Restoration Flows and downstream conveyance. The increased erosion would be temporary as the channel adjusts to the new profile and Restoration Flow regime. The Project would excavate portions of the former Pool impoundment area (i.e., the San Joaquin arm of Mendota Pool) to establish a new equilibrium channel slope to minimize the amount of sediments being washed downstream when Mendota Dam is lowered. Although there may be short-term erosion of potentially-contaminated sediments, increased flow rates would likely dilute potential pollutants to below water quality objectives.

When comparing Alternative C to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative C to the No-Action Alternative). The impact would be **less than significant**.

Impact SWQ-3 (Alternative C): ***Long-Term Effects on Water Quality from Floodplain Inundation of Prior Agricultural Soils.*** Long-term effects on water quality of Restoration Flows within the new floodplain under Alternative C would be the same as those described for Alternative A. Refer to SWQ-3 (Alternative A) for details. The primary different is that Alternative C does not include the Compact Bypass. This impact would be **potentially significant**.

Mitigation Measure SWQ-3 (Alternative C): ***Minimize Use of Pesticide and Herbicide Contaminated Soil.*** Refer to Mitigation Measure SWQ-3 (Alternative A). The same measure would be used here. Construction activities in the Project area will be modified to minimize use of contaminated soil. Implementation of this mitigation measure would reduce this impact to a **less than significant** level.

Impact SWQ-4 (Alternative C): ***Long-Term Effects on Water Quality from Agricultural Practices within the New Floodplain.*** Similar to the No-Action Alternative and existing conditions, agricultural practices under Alternative C would remain outside of the floodplain levees and direct impacts of those practices on water quality in the San Joaquin River would be limited. There would be **no impact**.

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Alternative D would entail construction of new Project facilities, including new levees to establish an approximately 4,200-foot-wide floodplain capable of safely conveying up to 4,500 cfs through the reach with 3 feet of freeboard. As with Alternative C, a new dam would be constructed across Fresno Slough to contain Mendota Pool so that up to 4,500 cfs of Restoration Flows can be conveyed downstream through the existing river channel and across the existing Mendota Dam into Reach 3. A portion of river sediments that have accumulated behind Mendota Dam would be removed and disposed of appropriately. A new North Canal and North Canal bifurcation structure, capable of delivering up to 2,500 cfs from the river in Reach 2B to Mendota Pool, would be constructed. Three potential locations have been identified for the North Canal bifurcation structure (RM 209.8, RM 213.4 and RM 214.2). The river control structure of the North Canal bifurcation structure would include fish passage facilities. Other key features include removal of the San Joaquin River control structure of the Chowchilla Bifurcation Structure, construction of fish passage facilities at Mendota Dam, a fish screen on the North Canal to prevent juvenile fish from entering Mendota Pool, and a fish barrier located just north of the Fresno Slough Dam to prevent adult fish from migrating into Fresno Slough during Kings River flood releases. The San Mateo Avenue crossing would be modified. Agricultural practices (e.g., annual crops, pasture, or floodplain-compatible permanent crops) would be allowed in the newly-created floodplain. Construction activity is expected to occur intermittently over an approximate 158-month timeframe.

Geomorphology

Impact GEM-1 (Alternative D): ***Substantially Altering the Existing Drainage Pattern, Including Alteration of the Course of the River, in a Manner which Would Result in Substantial On- or Off-Site Erosion***. Refer to Impact GEM-1 (Alternative A); the potential impact of the North Canal bifurcation structure would be essentially the same as the South Canal bifurcation structure. Refer also to Impact GEM-1 (Alternative C); the impact in the approximately 4.5-mile reach upstream from the existing Mendota Dam would be essentially the same. This impact would be **less than significant**.

Impact GEM-2 (Alternative D): ***Increased Aggradation or Degradation that Causes a Substantial Increase in Channel Instability within Reach 2B.*** Refer to Impact GEM-2 (Alternative C). Effects on the existing drainage pattern under Alternative D would be the same as those described for Alternative C. This impact would be **less than significant**.

Impact GEM-3 (Alternative D): ***Increases in Lateral Erosion that Could Damage Existing and/or Proposed Levees or Other Infrastructure within Reach 2B***. Refer to Impact GEM-3 (Alternative C). Effects on lateral erosion under Alternative D would be the same as those described for Alternative C. This impact would be **less than significant**.

Impact GEM-4 (Alternative D): ***Short- and Long-Term Increases in Sediment Load that Could Cause Substantial Increases in Channel Instability in Downstream Reaches***. Refer to Impact GEM-4 (Alternative C). Effects on short-and long-term increases in sediment load under Alternative D would be the same as those described for Alternative C. This impact would be **less than significant**.

Surface Water Quality

Impact SWQ-1 (Alternative D): ***Construction-Related Effects on Water Quality.*** Construction-related effects on water quality under Alternative D would be the same as those described for Alternative A. Refer to SWQ-1 (Alternative A) for details. The primary difference under Alternative D is the potentially longer construction duration of 8 to 13 years. This impact is considered to be **potentially significant**.

Mitigation Measure SWQ-1 (Alternative D): ***Development and Implementation of SWPPP.*** Refer to Mitigation Measure SWQ-1 (Alternative A). The same measure would be used here. A SWPPP will be developed and implemented which details the construction-phase erosion and sediment control BMPs and the housekeeping measures for control of contaminants other than sediment, as well as the treatment measures and BMPs to be implemented for control of pollutants once the Project has been constructed. This impact would be **less than significant** after mitigation.

Impact SWQ-2 (Alternative D): ***Long-Term Effects on Water Quality from Mobilization of Mendota Pool Sediments.*** Long-term effects on water quality of Mendota Dam modification under Alternative D would be the same as those described for Alternative C. Refer to SWQ-2 (Alternative C) for details. The impact would be **less than significant**.

Impact SWQ-3 (Alternative D): ***Long-Term Effects on Water Quality from Floodplain Inundation of Prior Agricultural Soils.*** Long-term effects on water quality of Restoration Flows within the new floodplain under Alternative D would be the same as those described for Alternative A. Refer to SWQ-3 (Alternative A) for details. The primary different is that Alternative C does not include the Compact Bypass. This impact would be **potentially significant**.

Mitigation Measure SWQ-3 (Alternative D): ***Minimize Use of Pesticide and Herbicide Contaminated Soil.*** Refer to Mitigation Measure SWQ-3 (Alternative A). The same measure would be used here. Construction activities in the Project area will be modified to minimize use of contaminated soil. Implementation of this mitigation measure would reduce this impact to a **less than significant** level.

Impact SWQ-4 (Alternative C): ***Long-Term Effects on Water Quality from Agricultural Practices within the New Floodplain.*** Long-term effects on water quality of agricultural practices within the new floodplain under Alternative D would be the same as those described for Alternative A. Refer to SWQ-4 (Alternative A) for details. The impact would be **less than significant**.

15.0 Hydrology - Wetlands and Aquatic Resources

This chapter describes the environmental and regulatory setting for wetlands and other non-wetland waters of the United States in the Project area, analyzes the environmental consequences associated with Project alternatives, and identifies wetland impacts and mitigation measures, as appropriate. For the purposes of this document, wetlands and other aquatic resources (e.g., streams, lakes, and ponds) are a subset of waters of the United States. Biological resources such as aquatic species (e.g., fish, invertebrates, vegetation) are addressed in the biological resource chapters (Chapters 5, 6 and 7).

15.1 Environmental Setting

During the past century, the aquatic resources of the San Joaquin River and the Project area have undergone substantial changes because of human related activities. Extensive wetland areas were drained or filled. Many introduced species have spread and contributed to elimination or marginalization of native species. The decline of wetlands and associated native species has become a matter of public concern.

15.1.1 Existing Conditions

Biological resources addressed in this section include wetlands and other non-wetland waters of the United States. Existing conditions are the baseline biological resource conditions at the time of the Notice of Preparation/Notice of Intent distribution in July 2009. The baseline condition of these biological resources was determined through review of scientific literature, existing data sources, and field wetland delineations. In the case of wetlands, field data were collected at later dates, after the start of Interim Flows. Therefore, the best available information to describe existing conditions was typically from the period after the start of Interim Flows. Interim Flows substantially amplified flows in the river and elevated ordinary high water marks (OHWM).[1]

15.1.2 Categories for Wetlands and Other Waters of the United States

Three categories of potential jurisdictional wetlands were identified in the Project area, as well as potential other waters of the United States. The three wetland categories were riparian wetland, wet meadow, and marsh. Table 15-1 summarizes the acreage of each category of potential jurisdictional wetland and other waters of the United States in the Project area. The California Department of Fish and Wildlife (DFW) considers riparian wetland, wet meadow, and marsh as sensitive natural communities due to their limited distribution in California (DFW 2009; Hickson 2009). These wetland habitat types are described below.

[1] The OHWM is defined as the upper boundary of the active river channel along the bank and by lack of vegetation below it.

Table 15-1.
Project Area Wetlands and Waters of the United States

Wetland and Non-Wetland Type	Area (acres)
Riparian Wetlands	181.3
Wet Meadows	54.5
Marshes	81.3
Non-Wetland Waters of the United States	473.3
Total Riparian, Wetlands, and Other Waters	790.4

Riparian Wetlands

There are two primary types of riparian wetlands in the Project area – riparian forest and riparian scrub. They are described and analyzed together because they typically co-occur.

Riparian forest consists of the Fremont cottonwood forest (*Populus fremontii* forest alliance) and Oregon ash groves (*Fraxinus latifolia* forest alliance), and these typically occur along levees, floodplain terraces, and in concave depressions. At higher elevation and better drained soils, Fremont cottonwood forest dominates and integrates with sandbar and black willow.

Riparian scrub usually occurs in disturbed habitats along ditches and levees. Riparian scrub vegetation grows 10 to 30 feet tall and is dominated by the following vegetation alliances: black willow thickets (*Salix gooddingii* woodland alliance), buttonwillow thickets (*Cephalanthus occidentalis* shrubland alliance), red willow thickets (*Salix laevigata* woodland alliance), arrow weed thickets (*Pluchea sericea* shrubland alliance), blue elderberry stands (*Sambucus nigra* shrubland alliance), California rose briar patches (*Rosa californica* shrubland alliance), sandbar willow scrub (*Salix exigua* shrubland alliance) and silver bush lupine scrub (*Lupinus albifrons* shrubland alliance). Black willow prevails at lower elevations near the bankfull elevation[2] in areas dominated by poorly drained soils and flat topography. Mixed marsh and wet meadow species often occur in the adjacent understory in the vicinity of the riparian wetlands.

Wet Meadows

Meadows are herbaceous communities dominated by mixtures of perennial grasses and forbs with other grass-like species, such as rushes (*Juncus* species) and sedges (*Carex* species). Some meadows in the Project area include scattered riparian shrubs and trees, but do not contain enough woody vegetation to be included in the riparian scrub or riparian woodland wetland categories. Wet meadows are often located adjacent to dry meadows and other upland areas that are higher above the groundwater table. They typically include flat or concave surface relief and occur in low-lying troughs and basins with poorly drained soils near the San Joaquin River or its tributaries. These site characteristics help maintain extended periods of soil saturation or flooding during the growing season. The vegetation alliances that occur in the wet meadow wetlands are yerba mansa meadows (*Anemopsis californica* herbaceous alliance), creeping rye grass

[2] The bankfull elevation occurs where the stream completely fills its channel at maximum capacity.

turfs (*Leymus triticoides* herbaceous alliance), salt grass flats (*Distichlis spicata* herbaceous alliance) and non-native annual grasslands.

Wet meadows occur throughout the Project area and are sometimes used for livestock grazing. They occur in swales, drainages, and on lower riparian terraces. These wetlands receive water from the high water table, overbank flooding and sheet drainage from excessive runoff during winter, spring, and early summer. Tarplant (*Centromadia pungens*), yerba mansa (*Anemopsis californica*), alkali heath (*Frankenia grandiflora*), salt grass (*Distichlis spicata*), and creeping wildrye (*Leymus triticoides*) often occur in wet meadows in the Project area. The higher quality wetlands of this type are located in the downstream portion of the reach, near Mendota Pool.

Marshes

The marsh wetlands in the Project area consist of mixed marsh vegetation alliances that are dominated by annual and perennial emergent vegetation with varying amounts of herbs and grass-like species. The vegetative cover is often very dense. In contrast to meadow communities, which have seasonally saturated soils, marsh communities have saturated or inundated soils throughout most of the year, except in some cases, during the dry months of late summer. River water retained by the Mendota Dam is the principal source of water for marshes in the Project area. The vegetation alliances that were observed in the marsh wetlands are California bulrush marsh (*Schoenoplectus californicus* herbaceous alliance), pale spike rush marshes (*Eleocharis macrostachya* herbaceous alliance) and cattail marshes (*Typha* species herbaceous alliance).

Potential Non-Wetland Other Waters of the United States

Additional aquatic elements in the Project area were identified as potential, jurisdictional non-wetland other waters of the United States based on the presence of defined bed and bank, drift lines and/or OHWM. These features (typically, the river channel between the OHWMs, areas of backed up water upstream of Mendota Dam, non-maintained irrigation and drainage ditches, and other small tributaries in the Project area) were mapped using a combination of field measurements and aerial photography. These waters of the United States lack hydrophytic vegetation[3] typically required to qualify as a wetland. Their limits are set by the OHWM. As directed by the Corps, the OHWM for potential other waters of the United States that are connected to the river is defined by the level on the bank that water reached during the highest Interim Flows in 2010. The limits of the OHWM for historical natural water features that are no longer connected to the river is indicated by physical characteristics such as a clear, natural line impressed on the bank, shelving, changes in the character of soil, destruction of terrestrial vegetation, the presence of litter and debris, or other appropriate means that consider the characteristics of the surrounding areas (Corps 2005). Actively managed agricultural irrigation ditches, stock ponds and larger agricultural ponds were not considered other waters of the United States.

[3] Hydrophytic vegetation refers to plants that are adapted to live in saturated soil, flooded areas, or high groundwater conditions.

15.2 Regulatory Setting

This section presents the applicable Federal, State, and local laws and regulations associated with waters of the United States in the Project area.

The U.S. Army Corps of Engineers (Corps) and the U.S. Environmental Protection Agency (EPA) define wetlands as "those areas that are saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for the life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas." Waters of the United States, as defined in 33 Code of Federal Regulations (CFR) 328.3(a) and 40 CFR 230.3(s), include:

- All waters which are currently used, were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters which are subject to the ebb and flow of the tide.
- All interstate waters including interstate wetlands.
- All other waters such as intrastate lakes, rivers, streams (including intermittent streams), mud flats, sand flats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural basins, the use, degradation, or destruction of which could affect interstate or foreign commerce including any such waters which are or could be used by interstate or foreign travelers for recreational or other purposes; or from which fish or shellfish are or could be taken and sold in interstate or foreign commerce; or which are used or could be used for industrial purposes by industries in interstate commerce.
- All impoundments of waters otherwise defined as waters of the United States under the definition.
- Tributaries of waters identified by the definition above.
- Territorial seas.
- Wetlands adjacent to waters (other than waters that are themselves wetlands) identified by the definition above.

Additional information about these natural resources can be found in the following documents:

- *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Arid West Region* (Corps 2008a).
- *A Field Guide to the Identification of the Ordinary High Water Mark in the Arid West Region of the Western United States, a Delineation Manual* (Corps 2008b).

Waters that are themselves wetlands, while they may or may not be under Federal jurisdiction, typically are under State jurisdiction.

15.2.1 Federal

Federal laws and regulations pertaining to waters of the United States located in the Project area are summarized briefly below. More detail on regulatory compliance procedures can be found in Chapter 27, "Consultation, Coordination, and Compliance" and the *Technical Memorandum on Regulatory Compliance* (San Joaquin River Restoration Program [SJRRP] 2011) for Reach 2B.

Clean Water Act

The Clean Water Act (CWA) is the major Federal legislation governing the water quality aspects of the project. The objective of the act is "to restore and maintain the chemical, physical, and biological integrity of the nation's waters." The CWA establishes the basic structure for regulating discharge of pollutants into the waters of the United States and gives EPA the authority to implement pollution control programs, such as setting wastewater standards for industries. In certain states such as California, EPA has delegated some water quality regulatory authority to State agencies.

Under Section 404 of the CWA, the Corps regulates the disposal of dredged and fill materials into "waters of the United States." These jurisdictional waters of the United States include intrastate lakes, rivers, streams (including intermittent streams), mudflats, sandflats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds, and wetlands adjacent to any water of the United States (33 CFR Part 328). In areas subject to tidal influence, Section 404 jurisdiction extends to the high-tide line plus adjacent wetlands. Certain waters of the United States are considered "special aquatic sites" because they are generally recognized as having particular ecological value. Such sites include sanctuaries and refuges, mudflats, wetlands, vegetated shallows, coral reefs, and riffle and pool complexes. Special aquatic sites are defined by EPA and may be afforded additional consideration in the permit process for a project.

Projects that impact jurisdictional wetlands and non-wetland waters of the United States require a permit from the Corps. There are two types of permits: individual permits and general permits. Individual permits include standard permits and letters of permission. General permits include nationwide permits, regional general permits, and programmatic general permits. Nationwide permits are issued by the Corps for specific types of activities that have minimal individual or cumulative adverse environmental impacts. Individual permits are required for more complex projects that exceed the impact threshold for nationwide permits.

Section 303 of the CWA requires states to adopt water quality standards for surface waters. The three major components of water quality standards are designated users, water quality criteria, and anti-degradation policy. Section 303(d) of the CWA requires States and authorized Native American tribes to develop a list of water quality-impaired segments of waterways. The list includes waters that do not meet water quality standards necessary to support the beneficial uses of a waterway, even after point sources of pollution have had minimum required levels of pollution control technology installed. Only waters impaired by "pollutants" (e.g., clean sediments, nutrients such as nitrogen and phosphorus, pathogens, acids/bases, temperature, metals, cyanide, and synthetic organic chemicals), not those impaired by other types of "pollution" (e.g., altered flow,

channel modification), are to be included on the list. Section 303(d) of the CWA also requires States to maintain a list of impaired water bodies so that a total maximum daily load (TMDL) of criteria pollutants can be established. A TMDL is a plan to restore the beneficial uses of a stream or to otherwise correct an impairment. It establishes the allowable pollutant loadings or other quantifiable parameters (e.g., pH, temperature) for a water body and thereby provides the basis for establishing water quality-based controls. The calculation for establishing TMDLs for each water body must include a margin of safety to ensure that the water body can be used for the purposes of State designation. Additionally, the calculation also must account for seasonal variation in water quality. The Central Valley Regional Water Quality Control Board (CVRWQCB) develops TMDLs for the San Joaquin River. The upstream end of Reach 2B is listed as impaired for invasive species and Mendota Pool is listed as impaired for mercury and selenium. The associated TMDLs are expected to be complete by 2021 (see Chapter 14.0, "Hydrology – Surface Water Resources and Water Quality.")

CWA Section 402 created the National Pollutant Discharge Elimination System permit program. This program covers point sources of pollution discharging into a surface water body. Stormwater discharges during Project construction would be subject to the permit requirements of the Construction General Permit, which requires the Project proponents to develop and implement a Stormwater Pollution Prevention Plan (see Chapter 14.0, "Hydrology – Surface Water Resources and Water Quality.")

Rivers and Harbors Act Section 10

Section 10 of the Rivers and Harbors Act (33 United States Code 401 et seq.) requires authorization from the Corps for construction of any structure over, in, or under, excavation of material from, or deposition of material into navigable waters of the United States. Reach 2B is considered a navigable section of the San Joaquin River (Corps 2014).

Executive Order 11990: Protection of Wetlands

This Executive Order (EO) directs Federal agencies to provide leadership and take action to minimize the destruction, loss, or degradation of wetlands, and to preserve and enhance the natural and beneficial values of wetlands in implementing civil works.

U.S. Coast Guard

The U.S. Coast Guard is responsible for approval of the location and plans of bridges and causeways constructed across navigable waters of the United States. In addition, the Coast Guard is responsible for approval of the location and plans of international bridges and the alteration of bridges found to be unreasonable obstructions to navigation. Project actions are not anticipated to affect the locations or plans of bridges or causeways constructed across navigable waters of the United States.

15.2.2 State of California

State laws and regulations pertaining to wetlands are discussed below.

Porter-Cologne Water Quality Control Act

Division 7 of the California Water Code, known as the Porter-Cologne Water Quality Control Act, regulates activities that affect water quality and authorizes the State Water Resources Control Board and the DFW to regulate wetland and non-wetland "Waters of the State" features, to allocate surface water rights, permit diversions, and to control the use of water throughout the State. Waters of the State are defined in California Water Code section13050, as amended, as "any surface water or groundwater, including saline waters, within the boundaries of the State."

California Fish and Game Code

Sections of the California Fish and Game Code provide environmental protections for fish and wildlife resources. Diversions, obstructions, or changes to the natural flow or bed, channel, or bank of any river, stream, or lake in California that supports wildlife resources are subject to regulation by DFW, pursuant to Fish and Game Code section 1602.

California State Lands Commission

The California State Lands Commission (CSLC) has exclusive jurisdiction over all ungranted tidelands and submerged lands owned by the State, and the beds of navigable rivers, sloughs, and lakes. A project cannot use these State lands unless a lease is first obtained from the CSLC.

California Harbors and Navigation Code

The California Harbors and Navigation Code details the jurisdictions of the California Department of Parks and Recreation, Division of Boating and Waterways , which focus development of public access to waterways, safety of vessels and boating facilities, and on-the-water safety. Coordination with the Division of Boating and Waterways regarding design standards for future boating facilities could be required for installing new or modifying existing boating facilities, such as boat ramps, docks, or marinas.

15.2.3 Regional and Local

Regional and local plans and policies pertaining to wetlands are discussed below. As required by State law, counties in the Project vicinity have developed their own general plans. At a minimum, these documents must address the topics of land use, transportation, housing, conservation, open space, noise, and safety. These documents serve as statements of county goals, policies, standards, and implementation programs for the physical development of a county, and include the *Fresno County General Plan Policy Document* (2000) and the *Madera County General Plan Policy Document* (1995).

Fresno County General Plan

The Fresno County General Plan Policy Document (Fresno County 2000) outlines several policies for wetlands and riparian areas.

- Policies OS-D.1 to OS-D.3 supports a no-net loss wetland policy for the county, required projects to mitigate for loss of wetlands functions and values, and requires that best management practices be used to reduce pollutants and siltation near wetlands.

- Policy OS-D.4 requires a riparian protection zone around natural watercourses with buffers of 100 feet in width as measured from the top of the bank of unvegetated channels and 50 feet in width as measured from the outer edge of the dripline of riparian vegetation.
- Policy OS-D.7 supports the management of wetland and riparian plant communities for passive recreation, groundwater recharge, nutrient storage, and wildlife habitats.

Madera County General Plan

The Madera County General Plan Policy Document (Madera County 1995) outlines several policies for wetlands and riparian areas.

- Policies 5.D.2 and 5.D.3 require that wetland loss be mitigated in both regulated and non-regulated wetlands through any combination of avoidance, minimization, or compensation and that projects be designed in such a manner that pollutants and siltation would not significantly adversely affect the value or function of wetlands.
- Policy 5.D.4 requires riparian protection zones around natural watercourses with buffers of 100 feet in width as measured from the top of bank of unvegetated channels and 50 feet in width as measured from the outer edge for the canopy of riparian vegetation.

15.3 Environmental Consequences and Mitigation Measures

15.3.1 Impact Assessment Methodology

In order to evaluate where wetlands and other aquatic resources could potentially occur in the Project area, records from the U.S. Geological Survey 7.5 minute quadrangle for Mendota Dam (quadrangle 381D) in the National Wetlands Inventory database, maintained by the U.S. Fish and Wildlife Service (USFWS) (USFWS 2009), and records from the surrounding eight quadrangles (Jamesan, Tranquillity, Coit Ranch, Firebaugh, Poso Farm, Firebaugh NE, Bonita Ranch and Gravelly Ford) were reviewed. In addition, the following literature and other data sources were reviewed to evaluate potential impacts to waters of the United States in the Project area:

- San Joaquin River Restoration Study Background Report (McBain and Trush 2002).
- National Wetlands Inventory Maps.
- Aerial photographs of the Project area and vicinity.
- U.S. Department of Agriculture soil surveys of Fresno and Madera Counties, California (Natural Resources Conservation Service [NRCS] 2015, Soil Conservation Service [SCS] 1971, SCS 1962).
- Standard biological references and field guides including the Jepson Manual (Hickman 1993).

Jurisdictional wetland delineation surveys were also performed in 2010 and 2011 in areas where access was granted from private landowners. Wetland delineations in the Project area were conducted in accordance with the methodology presented in the *Corps of Engineers Wetlands Delineation Manual* (Corps 1987) and the *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Arid West* (Corps 2008a). A full description of the methodology was provided in *Existing Environmental Conditions: Data Needs and Survey Approach* (SJRRP 2010). The extent of wetlands in areas where access was not granted was estimated based on field work on adjacent properties, contour maps and aerial photography.

Based on the presence of wetlands and other aquatic resources in the Project area, a methodology for impact evaluation for wetlands and other aquatic resources was developed. Waters of the United States identified in the Project area were overlaid with Project impact areas in a Geographic Information System platform to determine the types and extent of waters of the United States potentially affected by the Project.

Potential impacts of the Project on wetland resources were characterized by evaluating direct, indirect, temporary, and permanent impacts. Direct impacts include the removal or loss of wetlands within the footprint of ground disturbing actions. Indirect impacts result from changes to habitat that are incidental to project implementation such as altering the water supply to existing wetlands. Temporary impacts have a short duration, and wetlands would be expected to recover or be restored within 3 to 5 years after Project implementation. An example would be the temporary diversion of water flows to install infrastructure, followed by wetland re-establishment. A permanent impact would involve the long-term alteration of wetland habitats such as wetland filling, removal, or flooding or dewatering of an area. An example would be the lowering the normal water elevation adjacent to a marsh area which then forms an upland riparian terrace lacking hydrology for wetlands.

15.3.2 Significance Criteria

State California Environmental Quality Act (CEQA) Guidelines Appendix G and National Environmental Policy Act (NEPA) Council on Environmental Quality (CEQ) Regulations were used to determine the significance of wetland impacts. Impacts on wetlands were assessed by estimating the potential changes to the quantity and quality of wetland habitats expected to develop over time under the Project alternatives with the wetland habitats condition under the No-Action Alternative. A key assumption is that conditions predicted to result with implementation of each Project alternative would occur within 50 years of Project implementation.

Under NEPA CEQ Regulations, impacts must be evaluated in terms of their context and intensity. Significant impacts may be beneficial or adverse and are considered equally. An example of a significant beneficial impact would be the conversion of a cattail marsh habitat to a habitat with greater functions and values for less common or listed species (such as a yerba mansa meadow).

These factors have been considered when applying the State CEQA Guidelines, which state that the Project would result in a significant impact to wetland resources if it would

have a substantial adverse effect on any wetland riparian habitat, other wetland habitat, or other waters identified in local or regional plans, policies, or regulations, or by the DFW or USFWS. Examples of such effects are listed below.

- Have a substantial adverse effect either directly or indirectly on federally protected (jurisdictional) wetlands as defined by Section 404 of the CWA (including, but not limited to, marsh, riparian wetlands, seasonal wetlands etc.) through removal, filing, hydrological interruption, or other means.
- Have the potential to degrade the quality of the environment, substantially reduce the habitat of listed or sensitive wetland plant species or threaten to eliminate a wetland plant community.
- Conflict with any local policies or ordinances protecting wetland resources, such as a wetland protection policy, wetland protection ordinance, adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or State habitat conservation plan.

15.3.3 Impacts and Mitigation Measures

This section provides an evaluation of the effects of the Project alternatives on jurisdictional wetlands. With respect to wetlands and other waters of the United States, the primary environmental impact issue and concern is the following:

1. Fill, Fragment, Isolate, Divert, or Substantially Alter Potentially Jurisdictional Wetlands and Other Waters during Construction.
2. Fill, Fragment, Isolate, Divert, or Substantially Alter Potentially Jurisdictional Wetlands or Other Waters during the Operations and Maintenance Phase.
3. Conflict with Provisions of Local or Regional Plans Regarding Conservation Lands.

See also Chapter 6.0, "Biological Resources – Vegetation," for a discussion of impacts to riparian habitat and other sensitive vegetation communities and Chapter 7.0, "Biological Resources – Wildlife," for a discussion of habitat conservation plans. Other wetland-related issues covered in the Program Environmental Impact Statement/Report (PEIS/R) are not covered here because they are programmatic in nature and/or are not relevant to the Project area.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. However, other proposed actions under the SJRRP would be implemented, including habitat restoration, augmentation of river flows, and reintroduction of salmon. Without the Project in Reach 2B, however, these activities would not achieve the Settlement goals. The potential effects of the No-Action Alternative are described below. The analysis is a comparison to existing conditions, and no mitigation is required for No-Action.

Impact WET-1 (No-Action Alternative): *Fill, Fragment, Isolate, Divert, or Substantially Alter Potentially Jurisdictional Wetlands and Other Waters during*

Construction. Under the No-Action Alternative, facilities and channels would not be constructed or modified in the Project area. Actions that could fill, fragment, isolate, divert, or substantially alter wetlands or other waters of the United States would not be implemented. There would be **no impact**.

Impact WET-2 (No-Action Alternative): *Fill, Fragment, Isolate, Divert, or Substantially Alter Potentially Jurisdictional Wetlands and Other Waters during the Operations and Maintenance Phase.* Under the No-Action Alternative, Restoration Flows in Reach 2B may recruit new vegetation along the wetted channel banks and riparian habitat would mature in areas upstream of San Mateo Avenue low flow/dip crossing. Wetland habitats supported by Mendota Pool would be maintained by the relatively stable water level held by Mendota Dam. Creation and enhancement of riparian habitat upstream of Mendota Pool would be a **beneficial** effect.

Impact WET-3 (No-Action Alternative): *Conflict with Provisions of Local or Regional Plans Regarding Conservation Lands.* The No-Action Alternative would not reduce the effectiveness of the Madera and Fresno counties' general plan conservation strategies, and attainment of conservation plan goals and objectives would not otherwise be prevented. The No-Action Alternative could result in beneficial effects on these plans because it would support attainment of goals or objectives related to enhancing wetlands and riparian areas along Reach 2B. This would be a **beneficial** effect.

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

Alternative A would include construction of Project facilities including a Compact Bypass channel, a new levee system encompassing the existing river channel in a narrow floodplain, and the South Canal. Other key features include construction of the Mendota Pool Dike (separating the San Joaquin River and Mendota Pool), a fish barrier below Mendota Dam, and the South Canal bifurcation structure and fish passage facility, modification of the San Mateo Avenue crossing, and the removal of the San Joaquin River control structure at the Chowchilla Bifurcation Structure. Construction activity is expected to occur intermittently over an approximate 132-month timeframe.

This alternative includes passive riparian habitat restoration and grazing or farming in the floodplain. It is assumed that over time wetland communities would develop within the main channel and that a dense riparian scrubland would develop along the main river channel banks. The Restoration Flows would be used to recruit new vegetation along the channel from the existing seed bank. Between the main river channel banks and the proposed levees, limited agricultural practices (e.g., annual crops, pasture, or floodplain-compatible permanent crops) would occur.

Impact WET-1 (Alternative A): *Fill, Fragment, Isolate, Divert, or Substantially Alter Potentially Jurisdictional Wetlands and Other Waters during Construction.* Construction activities have the potential to result, indirectly or directly, in adverse effects on jurisdictional waters of the United States and waters of the State, including wetlands. Compared to the No-Action Alternative, implementing Alternative A would result in channel modifications in Reach 2B to divert the river into the Compact Bypass channel for fish passage. This and other actions may involve dredging, grading, and

recontouring within the OHWM of waters of the United States. As a result, dredged or fill materials would be discharged into waters of the United States, and permanent fill of Corps jurisdictional wetlands could occur.

Project actions to manage channel habitat may also result in temporary or permanent fill of waters of the United States, including wetlands. Channel habitat enhancement could involve dredging, grading, and recontouring to connect the existing channel to the Compact Bypass, which would result in discharge of fill material. In addition, some adjacent wetlands could be permanently filled or isolated by constructing control structures within the channel. These actions could result in loss of not only the filled wetlands, but any associated adjacent wetland habitat.

Construction of haul roads, staging areas, new levees, and other potential ancillary facilities could result in temporary or permanent fill of waters of the United States, including wetlands. Constructing and installing fish passage facilities, fish barriers, and new control structures, as well as modifying existing control structures and road crossings, and other Project actions, could also result in placement of fill into waters of the United States.

Although many of the Project actions could result in discharge of dredged or fill material into waters of the United States, including wetlands, most of these activities would not result in permanent loss of acreage, functions, or values of wetland habitats. New low-flow channel, side-channel, bypass channel, and floodplain habitat would be created and these and other modified areas of river reaches and bypasses would continue to convey water and support aquatic habitat.

Table 15-2 summarizes the impact acreage for Alternative A for each category of potentially jurisdictional wetlands and other waters in the Project area. These acreages represent the worst-case scenario where all existing floodplain areas are assumed to be impacted. “Infrastructure” generally refers to area permanently converted to structures, levees or roads. “Floodplain” refers to the floodplain of the San Joaquin River; the acreage impacted under this category may be disturbed up to 3 years following construction, but eventually would return to natural habitat or agriculture. “Borrow” refers to the maximum amount of habitat that could be disturbed to take fill materials for levees. Other impacts refer to construction staging areas, temporary access roads and other construction-related disturbances. Areas temporarily disturbed during construction would be restored to previous contours, if feasible, and then seeded with a native vegetation seed mixture to prevent soil erosion. Some areas, such as borrow areas, may not be feasible to restore previous contours, but these areas would be smoothed and seeded (see Section 2.2.4).

Table 15-2.
Wetlands and Waters of the United States Potentially Affected by Alternative A

Type	Maximum Impacted Area (acres)			
	Floodplain (future habitat or agriculture)	Infrastructure (not future habitat)	Borrow (future habitat or agriculture)	Other (future habitat or agriculture)
Riparian Wetlands	79.3	20.3	2.5	23.2
Wet Meadows	52.2	3.2	-	<0.02
Marshes	39.3	3.6	4.6	0.9
Non-Wetland Waters of the United States	351.6	50.5	9.9	31.9
Total Riparian, Wetlands, and Other Waters	522.4	77.7	17.0	56.0

Notes:
Floodplain = floodplain of the San Joaquin River (passive restoration and agricultural activities)
Infrastructure = structures, levees, or roads
Borrow = maximum amount disturbed to take fill materials for levees (reseeded)
Other = construction staging areas, temporary access roads, and other construction-related disturbances (reseeded)

The Project alternatives (including Alternative A) include specific conservation measures to avoid, minimize, or compensate for adverse effects on waters of the United States and waters of the State, including wetlands (as described in Table 2-8 of Chapter 2.0, "Description of Alternatives"), and these measures would be implemented as part of the Project alternative. Temporary impacts of the Project alternative would be minimized by implementation of conservation measures that require coordination with the Corps, identification and quantification of wetlands and waters of the United States/waters of the State, obtaining permits, and full compensation for any loss of wetlands and other waters of the United States/waters of the State. Implementing Conservation Measures WUS-1 and WUS-2 would ensure that loss and degradation of waters of the United States, and other wetland habitats, would be avoided and minimized during construction activities, to the extent feasible. Implementing Conservation Measures WUS-1 and WUS-2 would ensure that any wetland habitat or other waters of the United States that could not feasibly be avoided would be replaced, restored, or enhanced so that the Project would result in no net loss of aquatic acreage, functions, and values. Because conservation measures will be implemented as part of the Project, Alternative A would not have substantial effects on jurisdictional wetlands by construction of facilities or during other construction-related Project actions (e.g., habitat restoration).

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to No-Action Alternative). Impacts would be **less than significant**.

Impact WET-2 (Alternative A): ***Fill, Fragment, Isolate, Divert, or Substantially Alter Potentially Jurisdictional Wetlands and Other Waters during the Operations and Maintenance Phase.*** Compared to the No-Action Alternative, Alternative A would result in expanding the river's floodplain and increasing the flow conveyance capacity of the

reach. These changes, in combination with Restoration Flows, have the potential to result in both adverse and beneficial effects on jurisdictional waters of the United States and waters of the State, including wetlands. The increase in flows could permanently inundate and thus eliminate some wetlands, but also expand or create additional areas of wetlands. Additionally, the reduction in normal water elevation in certain portions of Reach 2B caused by removal of the influence of Mendota Pool would drain and dewater some wetlands during some portions of the year, but would also expand or create additional areas of wetlands. After Project completion, in most instances, affected waters of the United States would be expected to have improved habitat functions as compared to No-Action conditions for several reasons: (1) fish habitat would be enhanced, (2) floodplain habitat would be expanded and enhanced, and (3) riparian habitat would be enhanced.

Long-term passive riparian habitat restoration of the San Joaquin River would improve native floodplain and in-channel habitats. Perennial base flows and seasonal high flows in the river would promote the establishment of riparian vegetation, wet meadows, and marshes and increase overall floodplain connectivity. Alternative A would restore river-floodplain connectivity and longitudinal connectivity of riparian vegetation near the channel and enhance landscape connectivity between the river corridor and adjacent sloughs or tributary channels.

When comparing Alternative A to existing conditions, effects would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). According to habitat restoration estimates, Alternative A could support up to 720 acres of wetlands and other waters within hydric soils in of the floodplain and bypass area. This is a 10 percent increase in acreage as compared to existing conditions. Wetland plant species can also become established in other areas of the floodplain, however without hydric soils these other areas would not qualify as jurisdictional wetlands.[4] Alternative A is expected to result in long-term **beneficial** effects to wetlands and other waters.

Impact WET-3 (Alternative A): ***Conflict with Provisions of Local or Regional Plans Regarding Conservation Lands.*** Compared to the No-Action Alternative, Alternative A would not conflict with the provisions of the Fresno and Madera counties' general plans regarding conservation lands. The Project would not result in long-term net loss of acreage, functions, or values of wetland habitats or riparian areas, interfere with the management of conserved lands, or eliminate opportunities for conservation actions. The Project is expected to result in a long-term increase in wetland and riparian habitats. These consequences of implementing the Project would benefit general plans that strive to conserve, restore, and enhance these habitats. The Project would enhance opportunities to implement conservation strategies and attain conservation goals by providing hydrologic conditions and floodplain areas necessary to restore wetlands.

[4] Growth of hydrophytic plants in areas without hydric soils is generally rare and usually only happens in transition zones between wetlands and uplands, transitional zones at and below the OHWM, and where fill has occurred recently.

When comparing Alternative A to existing conditions, impacts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative A to the No-Action Alternative) and would result in supporting county general plans. This is a **beneficial** effect.

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Alternative B would include construction of Project features including a Compact Bypass channel, a new levee system with a wide, consensus-based floodplain encompassing the river channel, and the Compact Bypass Bifurcation Structure with fish passage facility. Other key features include construction of a fish passage facility at the San Joaquin River control structure at the Chowchilla Bifurcation Structure, the re-route of Drive 10 ½ (across the Compact Bypass control structure), and removal of San Mateo Avenue crossing. Construction activity is expected to occur intermittently over an approximate 157-month timeframe.

This alternative includes a mixture of active and passive riparian and floodplain habitat restoration and compatible agricultural activities in the floodplain. Active restoration planting would occur along the low flow channel of the river and in riparian establishment areas to establish a riparian area and seed bank, and floodplain areas would be seeded with native plants. Natural riparian recruitment (passive restoration) would promote continual habitat succession, particularly in areas where sediment is deposited or vegetation is removed by natural processes. Plantings that are wetland species or borderline wetland species would be irrigated as necessary during the establishment period of 3 to 5 years. Maintenance, monitoring, and long-term management would be conducted following revegetation.

Impact WET-1 (Alternative B): ***Fill, Fragment, Isolate, Divert, or Substantially Alter Potentially Jurisdictional Wetlands and Other Waters during Construction.*** Refer to Impact WET-1 (Alternative A). Potential impacts of Alternative B would be similar to potential impacts of Alternative A, with the following exceptions. Construction of the Project under Alternative B would affect the acreages of wetlands and other waters shown in Table 15-3. Alternative B has less potentially impacted area for each of the major Project impact categories (i.e., floodplain, infrastructure, borrow, and other) compared to Alternative A. As described under Impact WET-1 (Alternative A), avoidance, minimization, and compensation for loss of wetlands and other waters would reduce adverse effects during construction. Impacts of Alternative B would be **less than significant**.

Table 15-3.
Wetlands and Waters of the United States Potentially Affected by Alternative B

Type	Maximum Impacted Area (acres)			
	Floodplain	Infrastructure	Borrow	Other
	(future habitat)	(not future habitat)	(future habitat or agriculture)	
Riparian Wetlands	79.0	24.5	3.4	3.9
Wet Meadows	51.3	-	-	-
Marshes	47.3	0.1	3.2	0.9
Non-Wetland Waters of the United States	339.3	22.0	5.0	13.3
Total Riparian, Wetlands, and Other Waters	517.0	46.5	11.6	18.1

Notes:
Floodplain = floodplain of the San Joaquin River (returns to habitat)
Infrastructure = structures, levees, or roads
Borrow = maximum amount disturbed to take fill materials for levees (reseeded)
Other = construction staging areas, temporary access roads, and other construction-related disturbances (reseeded)

Impact WET-2 (Alternative B): ***Fill, Fragment, Isolate, Divert, or Substantially Alter Potentially Jurisdictional Wetlands and Other Waters during the Operations and Maintenance Phase.*** Refer to Impact WET-2 (Alternative A). Potential impacts for Alternative B are similar to potential impacts of Alternative A, with the following exceptions. According to habitat restoration estimates, Alternative B could support up to 840 acres of wetlands and other waters within hydric soils in of the floodplain and bypass area. This is more than a 40 percent increase in acreage compared to existing conditions. Wetland plant species could also become established in other areas of the floodplain, however without hydric soils these other areas would not become jurisdictional wetlands. Alternative B also includes natural channel erosion in Reach 2B (in the approximate 4 miles upstream of the Compact Bypass) and some sediment deposition in Reach 3 (in the approximate 1 mile downstream of the Compact Bypass) in order to re-establish stable sediment transport. Downcutting and sedimentation may affect existing wetland vegetation adjacent to the river channel, but new wetland vegetation would be expected to establish in these areas. Alternative B is expected to have long-term **beneficial** effects to wetlands and other waters.

Impact WET-3 (Alternative B): ***Conflict with Provisions of Local or Regional Plans Regarding Conservation Lands.*** Refer to Impact WET-3 (Alternative A). Potential impacts for Alternative B would be the same as potential impacts of Alternative A. This would be a **beneficial** effect.

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)
Alternative C would include construction of Project features including Fresno Slough Dam, a new levee system with a narrow floodplain encompassing the river channel, and the Short Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the Short Canal control structure and fish

screen, the Chowchilla Bifurcation Structure fish passage facility, modification of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 133-month timeframe.

Similar to Alternative B, Alternative C includes active riparian and floodplain habitat restoration. It is assumed that wetland communities would develop within the main channel, that a dense riparian scrubland would develop along the main river channel banks, and that bands of other habitat types (wetland, scrub, grassland, and forest) would develop at higher elevations along the channel corridor. The wetland, floodplain, and riparian areas would be planted following construction and then irrigated, monitored, maintained, and managed as necessary during the establishment period.

Impact WET-1 (Alternative C): ***Fill, Fragment, Isolate, Divert, or Substantially Alter Potentially Jurisdictional Wetlands and Other Waters during Construction.*** Refer to Impact WET-1 (Alternative A). Potential impacts of Alternative C would be similar to potential impacts of Alternative A. Construction of the Project would affect the acreages wetlands and other waters shown in Table 15-4. As described under Impact WET-1 (Alternative A), avoidance, minimization, and compensation for loss of wetlands and other waters would reduce adverse effects during construction. Impacts of Alternative C would be **less than significant**.

Table 15-4.
Wetlands and Waters of the United States Potentially Affected by Alternative C

Type	Maximum Impacted Area (acres)			
	Floodplain (future habitat)	Infrastructure (not future habitat)	Borrow (future habitat or agriculture)	Other (future habitat or agriculture)
Riparian Wetlands	112.1	13.8	11.7	18.6
Wet Meadows	52.2	-	-	<0.02
Marshes	48.1	6.4	3.0	7.2
Non-Wetland Waters of the United States	390.2	33.7	17.3	64.0
Total Riparian, Wetlands, and Other Waters	602.6	53.9	32.0	89.8

Notes:
Floodplain = floodplain of the San Joaquin River (active restoration)
Infrastructure = structures, levees, or roads
Borrow = maximum amount disturbed to take fill materials for levees (reseeded)
Other = construction staging areas, temporary access roads, and other construction-related disturbances (reseeded)

Impact WET-2 (Alternative C): ***Fill, Fragment, Isolate, Divert, or Substantially Alter Potentially Jurisdictional Wetlands and Other Waters during the Operations and Maintenance Phase.*** Refer to Impact WET-2 (Alternative A). Potential impacts for Alternative C are similar to potential impacts of Alternative A with the following exceptions. Alternative C includes active riparian and floodplain habitat restoration. Wetland, floodplain, and riparian areas would be planted following construction and then

irrigated and managed as necessary during the establishment period. According to habitat restoration estimates, Alternative C could support up to 760 acres of wetlands and other waters within hydric soils in of the floodplain and Fresno Slough Dam area. This would be a slight increase in acreage compared to existing conditions. Wetland plant species can also become established in other areas of the floodplain, however without hydric soils these other areas would not qualify as jurisdictional wetlands. Alternative C is expected to have long-term **beneficial** effects to wetlands and other waters.

Impact WET-3 (Alternative C): *Conflict with Provisions of Local or Regional Plans Regarding Conservation Lands.* Refer to Impact WET-3 (Alternative A). Potential impacts for Alternative C would be the same as potential impacts of Alternative A. This would be a **beneficial** effect.

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Alternative D would include construction of Project features including Fresno Slough Dam, a new levee system with a wide floodplain encompassing the river channel, and the North Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the North Canal bifurcation structure and North Canal fish passage facility, removal of the San Joaquin River control structure at the Chowchilla Bifurcation Structure, removal of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 158-month timeframe.

Similar to Alternative A, Alternative D includes passive riparian habitat restoration and farming in the floodplain. It is assumed that over time wetland communities would develop within the main channel and that a dense riparian scrubland would develop along the main river channel banks. The Restoration Flows would be used to recruit new vegetation along the channel from the existing seed bank. Between the main river channel banks and the proposed levees, limited agricultural practices (e.g., annual crops, pasture, or floodplain-compatible permanent crops) would occur.

Impact WET-1 (Alternative D): *Fill, Fragment, Isolate, Divert, or Substantially Alter Potentially Jurisdictional Wetlands and Other Waters during Construction.* Refer to Impact WET-1 (Alternative A). Potential impacts of Alternative D are similar to potential impacts of Alternative A, with the following exception. Construction of the Project would affect the acreages of wetlands and other waters shown in Table 15-5. As described under Impact WET-1 (Alternative A), avoidance, minimization, and compensation for loss of wetlands and waters would reduce the potential for adverse effects during construction. Impacts of Alternative D would be **less than significant**.

Table 15-5.
Wetlands and Waters of the United States Potentially Affected by Alternative D

Type	Maximum Impacted Area (acres)			
	Floodplain	Infrastructure	Borrow	Other
	(future habitat or agriculture)	(not future habitat)	(future habitat or agriculture)	
Riparian Wetlands	116.4	16.4	4.3	15.9
Wet Meadows	51.9	0.3	-	<0.02
Marshes	48.1	4.9	3.0	8.1
Non-Wetland Waters of the United States	376.2	65.5	6.0	58.2
Total Riparian, Wetlands, and Other Waters	592.7	87.1	13.3	82.2

Notes:
Floodplain = floodplain of the San Joaquin River (passive restoration and agricultural activities)
Infrastructure = structures, levees, or roads
Borrow = maximum amount disturbed to take fill materials for levees (reseeded)
Other = construction staging areas, temporary access roads, and other construction-related disturbances (reseeded)

Impact WET-2 (Alternative D): ***Fill, Fragment, Isolate, Divert, or Substantially Alter Potentially Jurisdictional Wetlands and Other Waters during the Operations and Maintenance Phase.*** Refer to Impact WET-2 (Alternative A). Potential impacts for Alternative D are similar to potential impacts of Alternative A. Alternative D includes passive riparian habitat restoration and farming in the floodplain. Restoration Flows would be used to recruit new vegetation along the channel from the existing seed bank. Between the main river channel banks and the proposed levees, agricultural practices (e.g., annual crops, pasture, or floodplain-compatible permanent crops) would occur. According to habitat restoration estimates, Alternative D could support up to 880 acres of wetlands and other waters within hydric soils in of the floodplain and Fresno Slough Dam area. This is more than a 15 percent increase in acreage compared to existing conditions. Wetland plant species can also become established in other areas of the floodplain, however without hydric soils these other areas would not qualify as jurisdictional wetlands. Alternative D is expected to result in long-term **beneficial** effects to wetlands and other waters.

Impact WET-3 (Alternative D): ***Conflict with Provisions of Local or Regional Plans Regarding Conservation Lands.*** Refer to Impact WET-3 (Alternative A). Potential impacts for Alternative D would be the same as potential impacts of Alternative A. This would be a **beneficial** effect.

16.0 Land Use Planning and Agricultural Resources

This chapter evaluates the potential land use and related agricultural impacts anticipated with implementation of the Project, including effects on agricultural resources due to farmland being removed from production. The analysis covers both short-term effects during construction and long-term effects resulting from implementation of restoration actions and operation of new Project facilities.

16.1 Environmental Setting

The agricultural and land use setting describes current land uses and ownership patterns in the Project area, which covers portions of Fresno and Madera counties in California. The predominant land use in the Project area is agriculture. Accordingly, the focus of this section is on agriculture, including cropping patterns, farmland designations as developed by the California Department of Conservation (DOC), and lands under Williamson Act contracts. Information is also provided on current land use and general plan designations. Collectively, this information provides context to the analysis of agricultural and land use impacts presented in Section 16.2. The data used to characterize existing land uses conditions in the Project area come from a variety of State and local sources as cited throughout the text.

16.1.1 Land Ownership

Land ownership in the Project area has been classified into three broad categories: public, private, and public trust (see Figure 16-1 and Table 16-1). Most of the land in the Project area (5,235 acres, or about 89 percent the Project area) is held in private ownership. The remaining land is either administered by various public agencies (377 acres, 6.4 percent) or is public trust land administered by the California State Lands Commission (CSLC) (191 acres, 3.2 percent). Public lands under the jurisdiction of the CSLC include both fee lands owned by the State and an easement interest in lands which are held in public trust.

As general background, the State of California acquired sovereign ownership of all tidelands and submerged lands and the beds of navigable waterways upon its admission to the United States in 1850. On navigable non-tidal waterways, such as the San Joaquin River, the State, acting by and through CSLC, holds fee ownership of the bed of the river landward to the ordinary low water mark and a public trust easement landward to the ordinary high water mark, except where there has been fill or artificial accretions or the boundary has been fixed by agreement or court decision. Such boundaries may not be readily apparent from present day site inspections. Whereas fee title in the bed of the river between the low water and high water marks is commonly held in private ownership, it remains subject to the public trust and the jurisdiction of CSLC. Private parties may not use the public trust easement area exclusively and uses within the

easement area must be consistent with common law public trust uses including commerce, navigation, fisheries, recreation, scientific study and the preservation of open space.

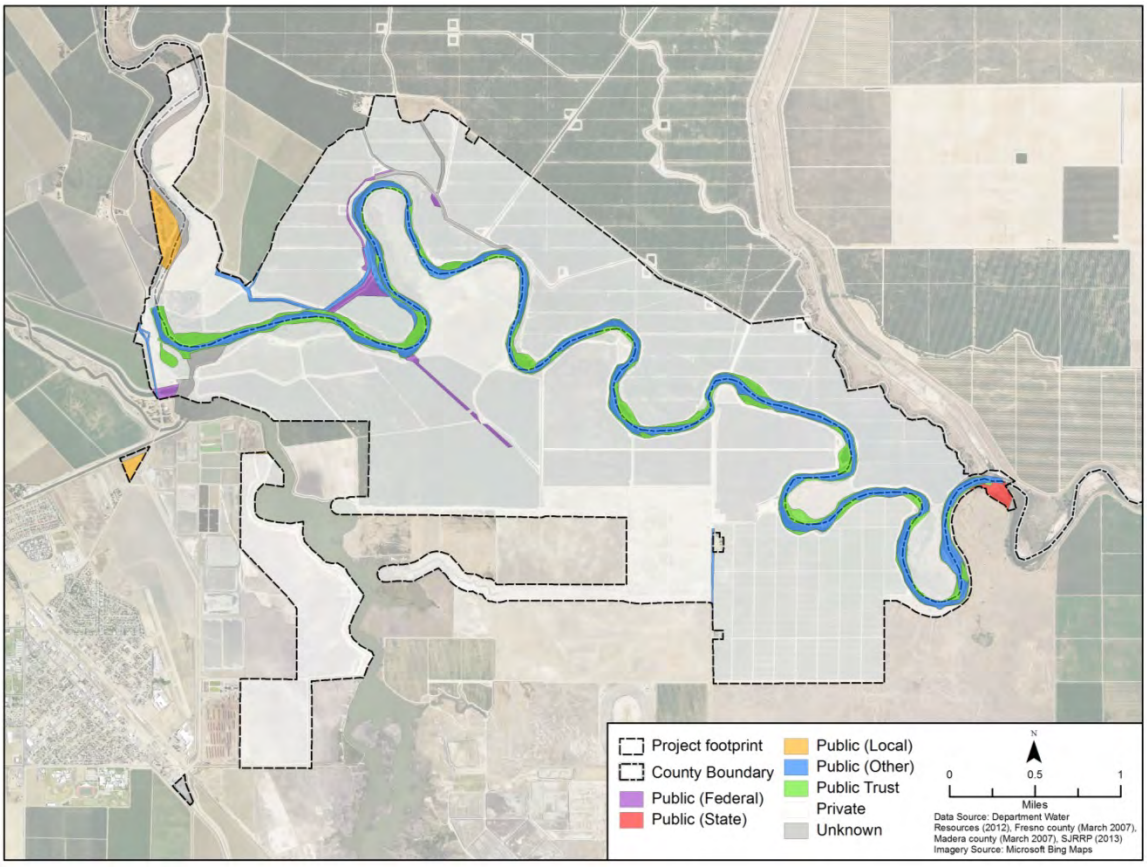

Figure 16-1.
Land Ownership in the Project Area

Table 16-1.
Land Ownership

Ownership	Acres	Percent (%)
Public	377	6.4
Federal	33	0.6
State	10	0.2
Local	37	0.6
Other	297	5.0
Private	5,235	88.8
Public Trust	191	3.2
Unknown	91	1.5
Total	**5,894**	**100.0**

Source: SJRRP 2011a, updated for this document

The extent of the CSLC's jurisdiction within the Project area is depicted on the Administrative Map for Reach 2B, which were developed at Reclamation's request in connection with the Project (CSLC 2011). A Record of Survey was filed for the San Joaquin River Administrative Map Reach 2B in both the Fresno and Madera County Recorder's Offices, respectively.

16.1.2 Land Use

Generally, the Project area is rural with most of the land along the river in agricultural production. For this analysis, land uses in the Project area have been classified into four general land use categories: (1) agricultural, (2) open space and undeveloped, (3) urban, and (4) water.[1] As shown in Figure 16-2 and Table 16-2, land use in Reach 2B is predominantly agricultural (4,227 acres, or 72 percent of the Project area) followed by open space and undeveloped land (1,242 acres, 21 percent), water (360 acres, 6.1 percent), and urban (14 acres, 0.2 percent). Additional information on cropping patterns is presented in Section 16.1.3. Although the extent of urban uses in the Project area is limited, the city of Mendota is located just west of the downstream portion of the Project area and several public roadways, including Bass Avenue and San Mateo Avenue travel through the area. Population in the city of Mendota was 11,167 in 2012 (California Department of Finance 2012).

16.1.3 Agricultural Production

The Project area is located within the San Joaquin Valley, a highly productive agricultural region in California. The region produces a wide variety of agricultural products, including, but not limited to, field crops, fruits, seed crops, tree nuts, and vegetables. The value of agricultural production in the region is substantial; refer to Chapter 21.0, "Socioeconomics and Economics" for more information on agricultural production values.

Cropping Patterns

Agriculture is the primary land use in the Project area and represents a key industry in the local and regional economy. Information on local cropping patterns was compiled for the Project area based on site surveys, California Department of Water Resources (DWR) land use data, and interviews with local landowners. Local agricultural production was classified into eight crop categories: alfalfa, almonds, cotton, grapes, grazing, other row crop, palms, and pistachios; vacant agricultural land was also identified. Existing cropping patterns in the Project area are presented in Figure 16-3 and Table 16-3.

Almonds are the largest single crop grown in the Project area, accounting for 45 percent of total agricultural acreage. The production of grapes (14 percent), other row crops (15 percent), and pistachios (12 percent) also represent important crops grown in the Project area. Approximately 10 percent of agricultural land in the Project area was not in active

[1] The land use data contain multiple categories that were aggregated as follows: Agricultural (citrus and subtropical; deciduous fruits and nuts; field crops; grain and hay crops; pasture; semi-agricultural and incidental to agriculture; truck, nursery and berry crops; and vineyards); Open Space and Undeveloped (idle, native vegetation, riparian vegetation, and vacant); Urban (industrial and urban); and Water (water surface). Some lands within the Project area were not surveyed with respect to current land use.

production. Based on cropping patterns, it is evident that local growers predominantly produce relatively higher-value permanent crops, namely nut crops.

Farmland Designations

The DOC, as part of its Farmland Mapping and Monitoring Program (FMMP), classifies land across the State into a range of agricultural land use categories based on technical soil ratings and current land use. This information is used to develop "Important Farmland" maps and track agricultural trends in the State. Below is a description of the FMMP mapping categories, which are defined, in part, by information from the U.S. Department of Agriculture. For more information on the FMMP, refer to Section 16.2.2.

- **Prime Farmland:** The best combination of physical and chemical features able to sustain long-term agricultural production.
- **Farmland of Statewide Importance:** Similar to Prime but with minor shortcomings such as greater slopes or less ability to store soil moisture.
- **Unique Farmland:** Farmland of lesser quality soils used for production of the State's leading agricultural crops.
- **Farmland of Local Importance:** Land of importance to the local agricultural economy as determined by each county's board of supervisors or local advisory committee.
- **Grazing Land:** Land with existing vegetation suited for livestock grazing.
- **Urban and Built-up Land:** Land occupied by structures used for residential, industrial, commercial, institutional, transportation yards, cemeteries, airports, golf courses, landfills, water or sewer treatment, or other developed purposes.
- **Other Land:** Land not included in any other mapping category. Often including low-density rural developments with brush, timber, or wetlands that are not suitable for livestock. This category includes strip mines, borrow pits, small bodies of water, and vacant and nonagricultural land surrounded on all sides by urban development.
- **Water:** Perennial bodies of water that are 40 acres or larger.

Figure 16-4 and Table 16-4 present the distribution of Important Farmland categories across the Project area. Most of the land in Reach 2B is considered designated Farmland[2] (about 76 percent of the Project area). Approximately 3,422 acres (58 percent) is considered Prime Farmland; 802 acres (14 percent) is Farmland of Statewide Importance; and 190 acres (3.2 percent) is Unique Farmland. In addition, Farmland of Local Importance accounts for approximately 565 acres (or 9.6 percent) in the Project area.

[2] Land considered "designated Farmland" consists of three farmland categories: Prime Farmland, Farmland of Statewide Importance, and Unique Farmland.

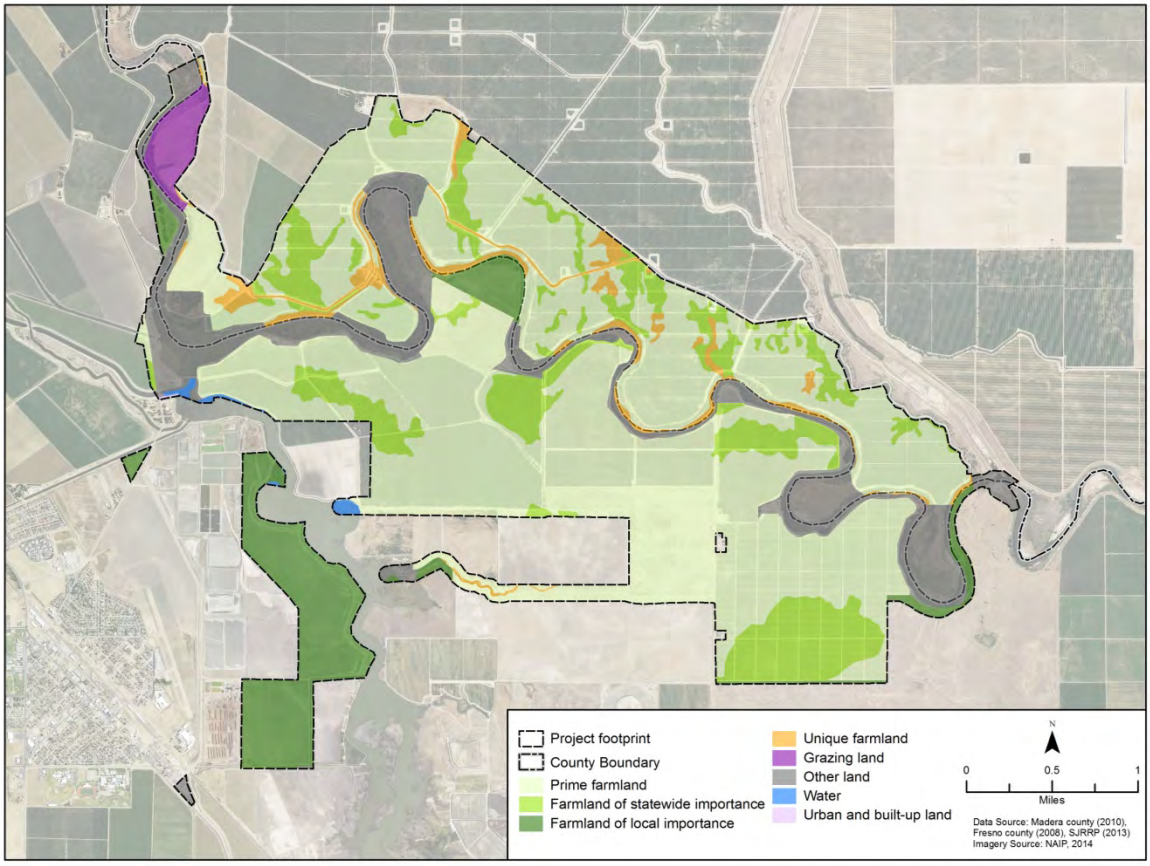

Figure 16-4.
Important Farmland in the Project Area

Table 16-4.
Important Farmland

Farmland Category	Acres	Percent (%)
Prime Farmland	3,422	58.1
Farmland of Statewide Importance	802	13.6
Unique Farmland	190	3.2
Farmland of Local Importance	565	9.6
Grazing Land	86	1.5
Urban and Built-Up Land	1	0.0
Other Land	807	13.7
Water	20	0.3
Total	**5,894**	**100.0**

Williamson Act

Some agricultural lands in California are protected under the California Land Conservation Act, commonly called the Williamson Act. (For more information on the Williamson Act, refer to Section 16.2.2.) Across California, approximately 15 million acres were enrolled in Williamson Act contracts in 2009 (DOC 2010b). At the local level, much of the farmland in Fresno and Madera counties is under Williamson Act contracts. Specifically, over 2.0 million acres were enrolled in Williamson Act contracts in the two-county region in 2009, which represent nearly 14 percent of the statewide total. Similarly, agricultural land in the Project area also tends to be covered under the Williamson Act. As shown in Figure 16-5 and Table 16-5, approximately 76 percent of lands (4,508 acres) within the Project area are under Williamson Act contract.

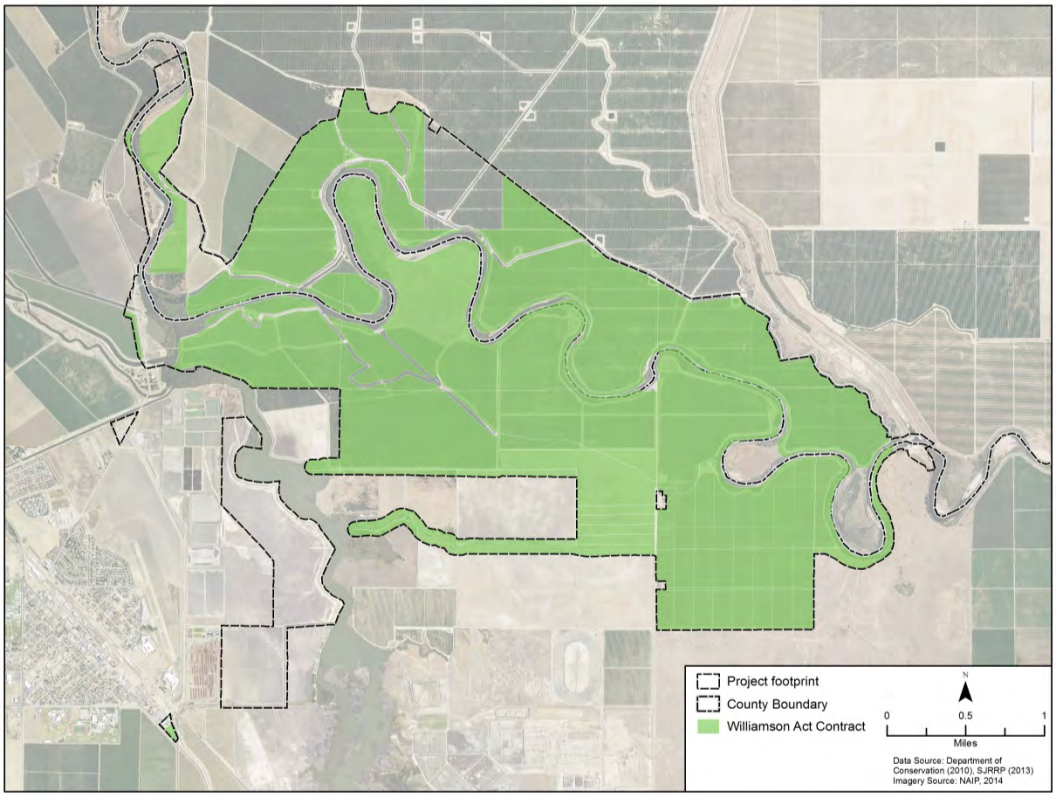

Figure 16-5.
Lands under Williamson Act Contract

Table 16-5.
Lands under Williamson Act Contract

Type	Acres	Percent (%)
Williamson Act Contract	4,508	76.5

16.1.4 Land Use Planning

Land use planning in the Project area is implemented by local governments, namely Fresno and Madera counties. Land use planning is dictated by applicable zoning regulations and general plans. Zoning ordinances govern current land use, including allowable land uses, intensity of use, and property development standards, while general plans provide the framework for future land use with a typical planning horizon of 15 to 25 years. For this analysis, various land use designations, as defined in the Fresno and Madera counties' general plans, were combined into common classifications. These designations reflect each county's vision of ultimate future land uses for the region. As presented in Figure 16-6 and Table 16-6, future land use in the Project area is planned to remain predominantly in agricultural production, with nearly 99 percent of the land area being designated for agricultural use. A relatively small portion of the Project area, approximately 1.3 percent, is designated for urban use by the local planning authorities, which consists of various residential, commercial, and industrial uses.

16.2 Regulatory Setting

The regulatory setting for land use and agricultural resources includes Federal, State, and local/regional regulations. Portions of the information presented below have been excerpted from the San Joaquin River Restoration Program (SJRRP) Program Environmental Impact Statement/Report (PEIS/R).

16.2.1 Federal

Farmland Protection Policy Act of 1981

The Farmland Protection Policy Act is intended to minimize the impact of Federal programs with respect to the conversion of farmland to nonagricultural uses. It ensures that, to the extent possible, Federal programs are administered to be compatible with State, local, and private programs and policies to protect farmland. The National Resources Conservation Service (NRCS) is the agency primarily responsible for implementing the Farmland Protection Policy Act.

The Farmland Protection Policy Act established the Farmland Protection Program and the Land Evaluation and Site Assessment (LESA) system. The NRCS administers the Farmland Protection Program, which is a voluntary program that helps purchase development rights to keep productive farmland in agricultural uses. The program provides matching funds to State, local, and tribal government entities and nongovernmental organizations with existing Farmland Protection Programs to purchase conservation easements. Participating landowners agree not to convert land to nonagricultural uses, and retain all rights to the property for future agriculture. A minimum 30-year term is required for conservation easements, and priority is given to applications with perpetual easements (NRCS 2013a). The LESA system is a tool used to rank lands for suitability and inclusion in the Farmland Protection Program. Land evaluations involve rating soils and placing them into groups ranging from the best to the least suited for a specific agricultural use, such as cropland, forestland, or rangeland. Site assessments involve three major areas: nonsoil factors related to agricultural use of a site, factors related to development pressures, and other public values of a site. Each factor selected is assigned a range of possible values according to local needs and objectives (NRCS 2013b).

16.2.2 State of California

The Public Trust Doctrine

The origins of the Public Trust Doctrine are traceable to Roman law concepts of common property. Under Roman law, the air, the rivers, the sea, and the seashore were incapable of private ownership; they were dedicated to the use of the public (Institutes of Justinian 2.1.1). Under English Common Law, this principle evolved into the Public Trust Doctrine pursuant to which the sovereign held the navigable waterways and submerged lands, not in a proprietary capacity, but as a "trustee of a public trust for the benefit of the people" (*Colberg, Inc. v. State of California ex rel. Dept. Pub. Works*, 67 Cal.2d 408, 416 [1967]).

Upon admission to the Union in 1850, California, as a sovereign state, received fee title to tide and submerged lands, as well as, the lands underlying navigable waterways (collectively referred to as "public trust lands") under the equal-footing doctrine (*Martin v. Waddell*, 41 U.S. 367, 410 [1842]). The Public Trust Doctrine, as a common law doctrine, is not static but is continuously evolving. Pursuant to the Public Trust Doctrine, public trust lands are owned by the State and held in trust for the benefit of the public. Public trust lands are not alienable in that all of the public's interest in them cannot be extinguished (*People v. California Fish Co.*, 166 Cal. 576, 597-99 [1913]; *Illinois Central v. Illinois*, 146 U.S. 387 [1892]; Cal. Const. Article X, Section 4; Pub. Resources Code, § 7991). Public trust lands cannot be bought and sold like other State-owned lands; only in rare cases may the public trust be terminated, and only where consistent with the purposes and needs of the trust (city of Long Beach v. Mansell, 3 Cal. 3d 462 [1970]). These lands are to be used to promote the public's interest in water dependent or water oriented activities including, but not limited to, water-related commerce, navigation, fisheries, environmental preservation and recreation.

The California Legislature, representing the people of California, is the ultimate trustee of California's public trust lands and resources and exercises its authority and responsibility to enact laws to protect and promote prudent use of public trust lands and the living resources therein. *National Audubon Society v. Superior Court*, 33 Cal. 3d 419 (1983) states that the core of the Public Trust Doctrine is the State's authority as sovereign to exercise a continuous supervision and control over the waters of the state to protect ecological and recreational values. The Legislature has delegated to the CSLC exclusive control and jurisdiction over ungranted public trust lands. (Pub. Resources Code, §§ 6216, 6301). The CSLC implements the Public Trust Doctrine through careful consideration of its principles and the exercise of discretion within the specific context and location of proposed uses. In administering its trust responsibilities, the CSLC exercises its discretionary authority in the best interests of the State, accommodating the changing needs of the public while preserving the public's right to use public trust lands for the purposes to which they are uniquely suited.

Use of public trust lands is generally limited to water dependent or related uses, including commerce, fisheries, and navigation, environmental preservation and recreation. Public trust uses include, among others, ports, marinas, docks and wharves, buoys, hunting, commercial and sport fishing, bathing, swimming, and boating. Ancillary or incidental

uses – those that directly promote trust use, are directly supportive and necessary for trust use, or that accommodate the public's enjoyment of trust lands – are also permitted. Public trust lands may also be kept in their natural state for habitat, wildlife refuges, scientific study, or use as open space (*Marks v. Whitney*, 6 Cal 3d 251 [1971]). Because public trust lands are held in trust for all citizens of California, they must be used to serve statewide goals, as opposed to purposes that are purely of local benefit (*Mallon v. City of Long Beach*, 44 Cal.2d 199 [1955]; Pub. Resources Code, § 6009). In addition, the living resources (e.g., the fish and aquatic plant and animal life) inhabiting public trust lands and the overlying waters are public trust resources and also subject to the protections of the Public Trust Doctrine.

State Planning and Zoning Laws

California Government Code section 65300 et seq. establishes the obligation of cities and counties to adopt and implement general plans. A general plan is a comprehensive, long-term strategy document that sets forth the expected location and general type of physical development expected in the city or county developing the document. The plan also may consider land outside its boundaries that, in the city's or county's judgment, may affect land use activities within its borders. The general plan addresses a broad range of topics, including, at a minimum, land use, circulation, housing, conservation, open space, noise, and safety. In addressing these topics, the general plan identifies the goals, objectives, policies, principles, standards, and plan proposals that support the city's or county's vision for the area. The general plan is a long-range document that typically addresses development over a 20-year period. Although the general plan serves as a blueprint for future development and identifies the overall vision for the planning area, it remains general enough to allow flexibility in the approach taken to achieve the plan's goals.

The State Zoning Law (Gov. Code, § 65800 et seq.) establishes that zoning ordinances, which are laws that define allowable land uses in a specific district, are required to be consistent with the general plan and any applicable specific plans. When amendments to the general plan are made, corresponding changes in the zoning ordinance may be required within a reasonable time to ensure that the land uses designated in the general plan also would be allowable by the zoning ordinance (Gov. Code, § 65860, subd. (c)).

Williamson Act

The California Land Conservation Act of 1965, commonly known as the Williamson Act, was enacted when population growth and rising property taxes were recognized as a threat to the viability of valuable farmland in California. It enables local governments to enter into contracts with private landowners to promote the continued use of relevant land in agricultural or related open space use. In return, landowners receive property tax assessments that are based on farming and open space uses instead of full market value. Local governments receive an annual subvention (subsidy) of forgone property tax revenues from the State via the Open Space Subvention Act of 1971.

The Williamson Act empowers local governments to establish "agricultural preserves" consisting of lands devoted to agricultural and other compatible uses. After such preserves are established, the locality may offer to owners of included agricultural land the opportunity to enter into annually renewable contracts that restrict the land to

agricultural use for at least 10 years (i.e., the contract continues to run for 10 years following the first date on which the contract is not renewed). In return, the landowner is guaranteed a relatively stable tax rate, based on the value of the land for agricultural/open space use only, and is unaffected by its development potential.

Contracts can be terminated only by a cancellation or nonrenewal. Cancellation of a Williamson Act contract involves an extensive review and approval process, in addition to payment of fees of up to 12.5 percent of the property value. The local jurisdiction approving the cancellation must find that the cancellation is consistent with the purpose of the California Land Conservation Act or is in the public interest. Several subfindings must be made to support either finding, as defined in Government Code section 51282. However, the Project may not require any cancellation procedure besides notification, because the land is needed by a public agency for a public use, as described in Government Code section 51291. This issue is described in the Project's *Technical Memorandum on Regulatory Compliance* (SJRRP 2011b) and Chapter 27, "Consultation, Coordination, and Compliance."

Filing for a nonrenewal, which can be done unilaterally by either the property owner or the local government, initiates a gradual increase in the property tax rate over the 10-year renewal period until it reaches the market rate by the end of the term. During the nonrenewal period, the property continues to be limited to uses allowed by the Williamson Act.

Farmland Security Zones

In August 1998, the legislature enhanced the Williamson Act with the Farmland Security Zone provisions. Farmland Security Zones, also known as Super Williamson Act lands, were established by the DOC with the same intent as Williamson Act contracts. The Farmland Security Zone provisions offer landowners greater property tax reductions in return for a minimum rolling contract term of 20 years. A Farmland Security Zone must be located in an Agricultural Preserve (area designated as eligible for a Williamson Act contract) and designated as Prime Farmland, Farmland of Statewide Importance, Unique Farmland, or Farmland of Local Importance. Land protected in a Farmland Security Zone cannot be annexed by a city or county government or school district. Farmland Security Zone contracts constitute nearly 2 percent of statewide Williamson Act enrollment (DOC 2007a).

A Farmland Security Zone can be terminated through a nonrenewal or cancellation. The nonrenewal allows a rollout process to occur over the remainder of the term of the contract, when the tax rates would gradually rise to the full rate by the end of the 20-year term. A cancellation must be applied for and approved by the director of the DOC, and specific criteria must be met. The cancellation must be in the public interest and consistent with Williamson Act criteria. If a cancellation is approved, fees equal to 25 percent of the full market value of the property must be paid (DOC 2007a).

California Important Farmland Inventory System and Farmland Mapping and Monitoring Program

The DOC maintains a statewide inventory of farmlands. These lands are mapped by the Division of Land Resource Protection as part of the FMMP. The FMMP was established by the State in 1982 to continue the Important Farmland mapping efforts begun in 1975 by the U.S. Soil Conservation Service (now called the NRCS). The intent of the NRCS was to produce agricultural resource maps based on soil quality and land use across the nation. The maps are updated every 2 years with the use of aerial photographs, a computer mapping system, public review, and field reconnaissance. As part of the nationwide effort to map agricultural land uses, the NRCS developed a series of definitions known as Land Inventory and Monitoring criteria. The Land Inventory and Monitoring criteria classify land's suitability for agricultural production. Suitability includes both physical and chemical characteristics of soils, as well as the actual land use. Maps of Important Farmland are derived from NRCS soil survey maps using the Land Inventory and Monitoring criteria and are available by county (DOC 2007b).

California Farmland Conservancy Program

The California Farmland Conservancy Program is a statewide grant funding program that supports local efforts to establish agricultural conservation easements and planning projects for the purpose of preserving important agricultural land resources (DOC 2007c). The California Farmland Conservancy Program provides grants to local governments and qualified nonprofit organizations for the following (DOC 2007d):

- Voluntary acquisition of conservation easements on agricultural lands that are under pressure of being converted to nonagricultural uses.
- Temporary purchase of agricultural lands that are under pressure of being converted to nonagricultural uses, as a phase in the process of placing agricultural conservation easements on farmland.
- Agricultural land conservation policy and planning projects.
- Restoration of and improvements to agricultural land already under easement.

Land Evaluation and Site Assessment Model (California)

Based on the Federal LESA system, the California LESA model was developed in 1997 to provide lead agencies with an optional methodology to ensure that potentially significant effects on the environment of agricultural land conversions are quantitatively and consistently considered in the environmental review process, including California Environmental Quality Act (CEQA) reviews. The California Agricultural LESA model evaluates measures of soil resource quality, a given project's size, water resource availability, surrounding agricultural lands, and surrounding protected resource lands. For a given project, the factors are rated, weighted, and combined, resulting in a single numeric score. The project score becomes the basis for determining a project's potential significance (DOC 1997).

16.2.3 Regional and Local

Regional and local regulations pertaining to land use and agricultural resources are based on allowable uses and policies outlined in local zoning and general plans implemented by Fresno and Madera counties.

Zoning

Zoning regulates the location of land uses and the development standards to which new development must be built. The purposes of establishing zoning designations are to ensure that neighboring land uses are compatible with one another and to regulate and protect the uses in which land may be placed. Each zoning designation contains specific regulations controlling the uses of land; density of population/structures; use, location, and dimensions of structures; open space/setback requirements; and access considerations.

Both Fresno and Madera counties implement their own set of zoning regulations. These regulations are applied when land is initially developed or redeveloped through permitting requirements. Based on existing land uses, it is assumed that zoning on most parcels in the Project area is “agricultural” in nature. Generally, agricultural zoning is designed to support and enhance agriculture land use and open spaces. The general descriptions of agricultural zoning designations in the two-county region are summarized below.

Agricultural zoning designations in Fresno County that are likely to be applicable to most land in the Project area include the following (Fresno County 2004):

- The **"AE" District** is intended to be an exclusive district for agriculture and for those uses which are necessary and an integral part of the agricultural operation. This district is intended to protect the general welfare of the agricultural community from encroachments of nonrelated agricultural uses which by their nature would be injurious to the physical and economic well-being of the agricultural district.
- The **"AL" District** is a limited agricultural district. It is intended to protect the general welfare of the agricultural community by limiting intensive uses in agricultural areas where such uses may be incompatible with, or injurious to, other less intensive agricultural operations. The district is also intended to reserve and hold certain lands for future urban use by permitting limited agriculture and by regulating those more intensive agricultural uses which, by their nature, may be injurious to nonagricultural uses in the vicinity or inconsistent with the express purpose of reservation for future urban use.

Agricultural zoning designations in Madera County include the following which focus on lot size (Madera County 2015):

- AR-5 Agricultural, Rural, Five Acre District..
- ARE-20 Agricultural Rural, Exclusive Twenty Acre District.
- AEX-20 Agricultural Exclusive, Twenty Acre District.

- ARE-40 Agricultural Rural, Exclusive Forty Acre District.
- AEX-40 Agricultural, Exclusive Forty Acre District.
- ARE-80, 160, 320, 640 Agricultural, Rural, Exclusive, 80 to 640 Acre District.
- ARV-20 Agricultural, Rural, Valley, Twenty Acre District.
- ARF Agricultural, Rural, Foothills District.

General Plans

As described above, each county and city in the state is required by Government Code section 65300 to have a comprehensive, long-term general plan for the physical development of the county or city. This section summarizes key features related to agriculture and open space in the general plans developed for Fresno and Madera counties. Representative general plan land use designations applicable to the Project area are presented in Section 16.1.4. These land use designations are implemented mainly through the local zoning ordinances referenced above.

Fresno County General Plan

The Fresno County General Plan was adopted in 2000 and is in the process of being updated. The two primary components of the General Plan that are applicable to the Project are the *Agriculture and Land Use Element* and *Open Space and Conservation Element*. Generally, general plan policies applicable within Fresno County are focused on maintaining the long-term viability of agriculture in the region (Fresno County 2000).

Madera County General Plan

The Madera County General Plan Policy Document, adopted in October 1995, is a stand-alone document that is part of the Madera County General Plan. Key general policies related to the protection of agriculture in Madera County are covered under the *Agriculture and Natural Resource* section of the plan (Madera County 1995).

16.3 Environmental Consequences and Mitigation Measures

16.3.1 Impact Assessment Methodology

The focus of this section is on physical changes in existing land use patterns in the Project area including agriculture, and secondarily, the consistency of the Project with local and regional land use plans and programs in Fresno and Madera counties.

To evaluate potential impacts on agricultural resources, the proposed footprint of the Project construction activities and long-term operational scenarios was evaluated in the context of existing agricultural operations to determine the extent (in acres) to which agricultural lands would be permanently removed from production. This evaluation was based on spatial overlays of the Project features (including borrow areas) on existing land use maps developed for the Project using Geographic Information System (GIS) analysis. In addition, the agricultural impact analysis also considered information on cropping patterns and representative crop yields to fully evaluate the magnitude of impacts on

agricultural values, which are evaluated in the Chapter 21.0, "Socioeconomics and Economics."

The groundwater resource analysis of potential seepage and high water table impacts was used to determine the extent of agricultural lands not proposed to be removed from production that could be affected in terms of agricultural productivity. This impact is evaluated qualitatively.

The assessment of agricultural resources also considered impacts related to conversion of designated Farmland (under the FMMP) to non-agricultural uses, as well as conflicts with Williamson Act contracts. This analysis evaluates the extent to which designated Farmland and properties under Williamson Act contract would be affected by the Project footprint using GIS analysis.

From a planning perspective, the Project is also evaluated with respect to its consistency with local general plans administered by Fresno and Madera counties. These plans have been reviewed in the context of Project activities to focus only on those sections that are relevant to the Project, including proposed land uses in the Project area, as well as policies related to open space preservation, conservation, and agriculture.

16.3.2 Significance Criteria

The Project was evaluated in accordance with the agricultural resources and land use and planning sections of the Environmental Checklist Form in Appendix G of the State CEQA Guidelines, as amended. Under National Environmental Policy Act (NEPA) Council on Environmental Quality Regulations, effects are evaluated in terms of their context and intensity. These factors have been considered when applying the State CEQA Guidelines. The Project would result in a significant impact on land use and agriculture if it would:

- Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance, as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Natural Resources Agency, to non-agricultural use.
- Conflict with existing zoning for agricultural use or a Williamson Act contract.
- Conflict with existing zoning for, or cause rezoning of, forest land (as defined in Pub. Resources Code, § 12220, subd. (g)), timberland (as defined in Pub. Resources Code, § 4526), or timberland zoned Timberland Production (as defined in Pub. Resources Code, § 51104, subd. (g)).
- Result in the loss of forest land or conversion of forest land to non-forest use.
- Involve other changes in the existing environment that, because of their location or nature, could result in conversion of Important Farmland to nonagricultural use or the substantial diminishment of agricultural land resource quality or importance.
- Physically divide an established community.

- Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the Project (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect.
- Conflict with any applicable habitat conservation plan or natural community conservation plan.

16.3.3 Impacts and Mitigation Measures

This section provides an evaluation of the direct and indirect effects of the Project Alternatives on agricultural and other land uses in the Project area. It includes analyses of potential effects relative to No-Action conditions in accordance with NEPA and potential impacts compared to existing conditions to meet CEQA requirements. The analysis is organized by Project alternative with specific impact topics numbered sequentially under each alternative. With respect to agricultural and land use, the environmental impact topics are:

1. Removal of Land from Agricultural Production.
2. Conversion of Designated Farmland to Non-Agricultural Uses.
3. Conflict with Williamson Act Contracts.
4. Degradation of Agricultural Land Productivity due to Seepage.
5. Conflict with Applicable Land Use Plans Regarding Agricultural Lands.
6. Diminishment of Agricultural Production by Increased Disease.

Other agriculture and land use-related issues covered in the PEIS/R are not covered here because they are programmatic in nature and/or are not relevant to the Project area. These include conversion of riparian forest to non-forest uses; physically divide or disrupt an established community; potential conversion of riparian forest because of altered inundation; and substantial diminishment of agricultural land resource quality and importance because of altered water deliveries. The issue of potential conflicts with habitat conservation plans is addressed in Chapter 7.0, “Biological Resources – Wildlife."

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. Existing levee alignments and heights would be maintained and maximum conveyance would be limited to the existing channel capacity. However, other proposed actions under the SJRRP would be implemented, including habitat restoration in other reaches, augmentation of river flows, and reintroduction of salmon. Without the Project in Reach 2B, however, Program-level activities would not achieve the Settlement goals. For the No-Action Alternative, the analysis of effects related to agricultural resources and land use is based on a comparison to existing conditions. No mitigation is required for No-Action.

Impact LU-1 (No-Action Alternative): ***Removal of Land from Agricultural Production***. Under the No-Action Alternative, the Project would not be implemented;

therefore, there would be no direct effects on agricultural production in the Project area associated with habitat restoration activities and/or construction and operation of new facilities. However, program-wide restoration activities would still be implemented, including Restoration Flows in the San Joaquin River. In Reach 2B, Restoration Flows would not exceed channel capacity and flood flows would be contained within the existing river channel or diverted into the Chowchilla Bypass when flood releases approach channel capacity, thereby avoiding direct effects on agricultural production in the Project area. (Indirect effects from seepage are described below under Impact LU-4.) Further, it is unlikely that agricultural land would be developed to accommodate potential population growth based on implementation of program-wide restoration activities in adjacent reaches of the river, which would discourage urban development in the region. Compared to existing conditions, no lands would be removed from production. There would be **no impact** associated with removing land from agricultural production under the No-Action Alternative.

Impact LU-2 (No-Action Alternative): ***Conversion of Designated Farmland to Non-Agricultural Uses***. Under the No-Action Alternative, there would be no direct effects on agricultural production in the Project area; refer to Impact LU-1 (No-Action Alternative) above. Accordingly, farmland designated as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance within the Project area would remain in agricultural production. Compared to existing conditions, there would be **no impact** associated with the conversion of designated Farmland to non-agricultural uses under the No-Action Alternative.

Impact LU-3 (No-Action Alternative): ***Conflict with Williamson Act Contracts***. Under the No-Action Alternative, there would be no direct effects on agricultural production in the Project area; refer to Impact LU-1 (No-Action Alternative) above. Therefore, agricultural lands in the Project area which are under Williamson Act contract would remain in active production and would remain in compliance with all contract provisions related to continued agricultural use. Compared to existing conditions, there would be **no impact** associated with conflicts with Williamson Act contracts under the No-Action Alternative.

Impact LU-4 (No-Action Alternative): ***Degradation of Agricultural Land Productivity due to Seepage***. Prior to the start of Interim Flows in October 2009, portions of the Project area historically experienced groundwater seepage to adjacent lands during elevated flood flows. Under the No-Action Alternative, Restoration Flows could affect agricultural lands in Reach 2B that have historically experienced groundwater seepage. Restoration flows could saturate areas for longer and more frequent periods, than flood flows under prior conditions. Restoration flows also could inundate areas during seasons when flood flows do not typically occur (i.e., summer and fall). These changes in duration, frequency, and seasonality could affect agricultural productivity by saturating soil in the rooting zone, impairing plant growth and survival, temporarily reducing grazing suitability, or interfering with the ability to use machinery to work soil. Most of these effects would be adverse and may necessitate changes in cropping patterns or grazing practices. At some sites, these adverse changes could cause agricultural land to be idled or otherwise reduce the land's quality and importance for agriculture. However,

Program-level seepage management measures would be implemented in the Project area that would minimize impacts to agricultural resources under the No-Action Alternative. Specifically, Restoration Flows would be managed such that the capacity of Reach 2B would not be exceeded. Consequently, adverse effects to agricultural productivity from Restoration Flows in Reach 2B would be minimized under the No-Action Alternative. Compared to existing conditions, there would be a **less-than-significant** impact related to the degradation of agricultural land productivity due to seepage of Restoration Flows under the No-Action Alternative.

Impact LU-5 (No-Action Alternative): ***Conflict with Applicable Land Use Plans Regarding Agricultural Lands***. Under the No-Action Alternative, there would be no direct change in existing agricultural or other land uses in the Project area. Although agricultural productivity may be affected due to seepage, the area would not be developed and would retain its agricultural character. As such, the No-Action Alternative would not conflict with applicable zoning regulations or general plan land use designations implemented by Fresno and Madera counties. Compared to existing conditions, there would be **no impact** related to conflicts with applicable land use plans in the Project area.

Impact LU-6 (No-Action Alternative): ***Diminishment of Agricultural Production by Increased Disease***. Under the No-Action Alternative, additional riparian vegetation upstream of the San Mateo Avenue crossing could affect the incidence of some orchard and vineyard diseases on adjacent land by serving as a source of causal organisms. However, the additional sources of causal organisms would not substantially reduce agricultural activity for several reasons: disease-causing organisms could already occur on a variety of widely planted fruit and nut crops present in the Project area, the incidence of disease is not solely or even primarily determined by the presence of causal organisms in the vicinity of an orchard or vineyard, and incidence of disease is only one of many factors affecting agricultural productivity. This impact would be **less than significant**.

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

All of the Project alternatives, including Alternative A, propose habitat restoration activities in conjunction with an expanded floodplain and widened levee alignments, as well as new Project facilities that promote fish passage through Reach 2B. This alternative includes passive riparian habitat restoration and farming in the floodplain. Under Alternative A, agricultural uses that are suitable within the proposed floodplain would be allowed. Construction activity is expected to occur intermittently over an approximate 132-month timeframe.

Impact LU-1 (Alternative A): ***Removal of Land from Agricultural Production***. Compared to No-Action, Alternative A would result in the removal of land from agricultural production in the Project area. As shown in Table 16-7, there are approximately 4,166 acres of land in agricultural production in the footprint of Alternative A. Of this total, about 1,232 acres would be subject to permanent loss of agricultural production, which includes the area underlying the proposed levee alignments and structures, borrow areas, and passive riparian habitat restoration areas within the floodplain. In addition, another 56 acres of farmland would be temporarily

disturbed during the 11-year construction period to accommodate features such as staging areas and access roads. Agricultural activity would be allowed on the floodplain within the proposed levee alignment (outside riparian habitat restoration areas) under Alternative A, up to 579 acres,[3] however, because this area would be subject to frequent inundation, it is likely that agricultural activity would primarily be livestock grazing, a relatively low-value type of agriculture use compared to permanent and annual crop production that generate higher economic returns. Agricultural production on the remaining farmland within Alternative A, roughly 2,299 acres, would not be affected.

Table 16-7.
Effects on Agricultural Land Uses

Type of Agricultural Effect	Alt. A (acres)	Alt. B (acres)	Alt. C (acres)	Alt. D (acres)
Permanent Agricultural Loss [a]	1,232	1,032	1,567	1,347
Temporary Agricultural Loss	56	42	73	69
Shift in Agricultural Land Use	579	886	0	956
No Agricultural Effect [b]	2,299	2,252	2,450	1,835
Total	***4,166***	***4,212***	***4,090***	***4,208***

Notes:

[a] Includes 350 acres of borrow area that are assumed to permanently removed from production.

[b] Includes land within potential borrow areas that are outside the required 350 acres of borrow pits.

Table 16-8 shows agricultural impacts by crop type. The Project would affect both permanent and annual crops, with the greatest impacts expected on almonds, which account for about 31 percent of the agricultural land that would be taken out of production permanently.[4] Other crops that would be taken out of production on a long-term basis include, but are not limited to, pistachios (15 percent), grapes (13 percent), row crops (13 percent), and vacant agricultural land (23 percent).

When comparing Alternative A to existing conditions, impacts to agricultural land uses would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to No-Action). In summary, the Project would remove agricultural land from production over both the short term (i.e., during construction) and long term (i.e., into perpetuity) as lands are managed to meet the objectives and goals of the Settlement Agreement; this impact is considered **significant**.

[3] This is an assumed value that provides a maximum amount of agricultural activity on the floodplain while still allowing for riparian habitat restoration in the Project area.

[4] These values account for both the permanent loss and the shift in agricultural activity for each type of crop.

Table 16-8.
Agricultural Effects by Crop Type, Alternative A

Crop Type	Type of Effect			
	Permanent Loss (acres)	Temporary Loss (acres)	Shift in Agricultural Activity (acres)	No Effect (acres)
Alfalfa	36	3	12	29
Almonds	399	3	163	1,321
Cotton	2	0	0	5
Grapes	224	20	11	368
Grazing	41	0	0	1
Other Row Crop	200	8	35	332
Palm	8	0	2	0
Pistachio	124	20	145	230
Agriculture-Vacant	200	1	212	13
Total	**1,232**	**56**	**579**	**2,299**

Mitigation Measure LU-1 (Alternative A): ***Preserve Agricultural Productivity of Designated Farmland to the Extent Possible.*** Project proponents will recognize and minimize adverse effects on agricultural lands to the extent practicable, including modification of construction practices. The following activities would minimize adverse effects on existing agricultural land in production and limit the extent of farmland that would be converted to non-agricultural uses. However, this mitigation measure will not fully avoid the conversion of substantial amount of agricultural land to non-agricultural uses, and there are no additional measures to fully mitigate the loss of farmland; therefore, this impact would be **significant and unavoidable**.

Implementation Action: The following actions will be implemented opportunistically, where feasible, appropriate, and consistent with the purpose, need, and objectives of the Project. These following measures are summarized, in part, from the Record of Decision (ROD) for the San Joaquin Restoration Program (SJRRP 2012b):

- When selecting sites for borrow excavation, minimize the fragmentation of lands that are to remain in agricultural use and retain contiguous parcels of agricultural land of sufficient size to support their efficient use for continued agricultural production.
- Where the levee system would transect agricultural properties, and the landowners desire to continue agricultural use on the portions located within the levee system, provide a means of convenient access to these properties.

- The Project proponent will either (1) acquire agricultural conservation easements for designated Farmland/Important Farmland[5] at a 1:1 ratio to be held by land trusts or public agencies who will be responsible for enforcement of the deed restrictions maintaining these lands in agricultural use, or (2) provide funds to a land trust or government program that conserves agricultural land sufficient to obtain easements on comparable land at a 1:1 ratio.
- Stockpile the upper 2 feet of soil from Project structural feature footprints that are designated Farmland. Stockpiled soil would be used in subsequent restoration of agricultural uses or redistributed for agricultural purposes.
- Restore for agricultural uses in those portions of borrow sites and of levee, bypass, and other Project feature footprints that are designated Farmland and are not converted to Project features, managed habitat, or Project mitigation for nonagricultural impacts. Restoration for agricultural use would include redistribution of salvaged topsoil and earthwork for necessary irrigation and drainage.
- Redistribute the most productive salvaged topsoil from structural feature footprints that is not used in restoring agricultural uses to affected designated Farmland. Redistribution will be to less productive agricultural lands near but outside the levee setback and Mendota Pool. Bypass areas that could benefit from the introduction of good-quality soil. By agreement between U.S. Department of the Interior, Bureau of Reclamation (Reclamation) or landowners of affected properties and the recipient(s) of the topsoil, the recipient(s) must use the topsoil for agricultural purposes.
- Minimize disturbance of designated Farmland and continuing agricultural operations during construction by implementing the following measures: (1) locate construction laydown and staging areas on sites that are fallow, disturbed, or to be discontinued for use as agricultural land to the extent possible, and (2) use existing roads to access construction areas to the extent possible.
- Coordinate with growers to develop appropriate construction practices to minimize construction-related impairment of agricultural productivity. Practices may include coordinating the movement of heavy equipment within the levee setback and Mendota Pool Bypass areas and implementing traffic control measures outside these areas.
- Comply with California Government Code sections 51290–51295 with regard to acquiring lands under Williamson Act contract. Specifically, whenever it appears that land within a preserve or under contract may be required for a public improvement, the DOC and the city or county responsible for administering the preserve must be notified (§ 51291, subd. (b)). Within 30 days of being notified, the DOC and the city or county would forward

[5] The term “designated Farmland” used in this section is synonymous with “Important Farmland” as referenced in the ROD (DOC classifications: Prime Farmland, Unique Farmland, and Farmland of Statewide Importance).

comments, which would be considered by the Project proponents (§ 51291, subd. (b)). The Williamson Act contract would be terminated when the land is acquired (§ 51295). The DOC would be notified within 10 working days upon completion of the land acquisition (§ 51291, subd. (c)). If, after acquisition, the Project proponents determine that the property would not be used for the proposed public improvement, the DOC and the city or county administering the involved preserve will be notified before the land is returned to private ownership. The land would be reenrolled in a new contract or encumbered by an enforceable restriction at least as restrictive as that provided by the Williamson Act (§ 51295).

- The Project proponent will coordinate with landowners and agricultural operators to sustain existing agricultural operations, at the landowners' discretion, within the Project area until the individual agricultural parcels are needed for Project construction.

Location: Agricultural lands within the Project area.

Effectiveness Criteria: Effectiveness will be based on annual reporting of the number of acres removed from agricultural production during implementation.

Responsible Agency: Reclamation and CSLC.

Monitoring/Reporting Action: Adequacy of the proposed activities will be confirmed with Reclamation project managers and CSLC monitors.

Timing: Mitigation will be ongoing over the construction timeframe.

Impact LU-2 (Alternative A): ***Conversion of Designated Farmland to Non-Agricultural Uses***. Compared to No-Action, Alternative A would result in the conversion of designated Farmland in the Project area to non-agricultural uses (Table 16-9). For this analysis, Farmland under the FMMP covers land designated as Prime Farmland, Farmland of Statewide Importance, and Unique Farmland. Specifically, Alternative A would permanently remove 786 acres of Prime Farmland, 94 acres of Farmland of Statewide Importance, and 120 acres Unique Farmland from agricultural production to accommodate the proposed levees, floodplain restoration, and Project structures.[6] An additional 350 acres of land would be required for borrow material to support construction activities; the exact location of the borrow areas is not known, although they are likely to occur on designated Farmland, which comprises about 88 percent of potential borrow areas under Alternative A. During construction, another 65 acres of designated Farmland would be temporarily taken out of production, but could return to active agriculture once the Project is complete. Lastly, approximately 480 acres of designated Farmland is located within the proposed floodplain, which would be available for agricultural activity (likely livestock grazing).

[6] These assumed values provide a maximum amount of agricultural activity on the floodplain while still allowing for riparian habitat restoration in the Project area.

Table 16-9.
Conversion of Designated Farmland

Farmland	Alt. A (acres)	Alt. B (acres)	Alt. C (acres)	Alt. D (acres)
Permanent Loss of Designated Farmland [a]				
Prime Farmland	786	585	939	917
Farmland of Statewide Importance	94	86	163	112
Unique Farmland	120	114	116	113
Additional Farmland within the Floodplain [b]	≤480	≤786	--	≤862
Borrow Areas	≤350	≤350	≤350	≤350
Temporary Loss of Designated Farmland [a]				
Staging Areas	65	50	81	77

Note:
[a] Designated Farmland includes Prime Farmland, Farmland of Statewide Importance, and Unique Farmland
[b] Primarily converted to open space or grazing land.

With some of the Project features, particularly where farmland remains undeveloped, the land would retain some of its agricultural value and long-term agricultural viability; however, because the proposed Reach 2B component of the Restoration Program is a long-term effort, these lands would not likely return to active crop production and are considered to be converted to non-agricultural uses.

When comparing Alternative A to existing conditions, impacts to designated Farmland under the FMMP would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative A to No-Action). In summary, the Project would remove Prime Farmland, Farmland of Statewide Importance, and Unique Farmland from production over both the short and long term; this impact is considered **significant**.

Mitigation Measure LU-2 (Alternative A): ***Preserve Agricultural Productivity of Designated Farmland to the Extent Possible.*** Refer to Mitigation Measure LU-1 (Alternative A). The same mitigation measure would apply to this impact. Project proponents will recognize and minimize adverse effects on agricultural lands to the extent practicable, including modification of construction practices. However, this mitigation measure would not fully avoid the conversion of agricultural land to non-agricultural uses, and there are no additional measures to fully mitigate the loss of farmland; therefore, this impact would be **significant and unavoidable**.

Impact LU-3 (Alternative A): *Conflict with Williamson Act Contracts*. Compared to No-Action, implementation of Alternative A would result in potential conflicts with Williamson Act contracts in effect on agricultural properties in the Project area. In total, approximately 433 acres under Williamson Act contract are located in areas underlying the proposed levee system and other Project facilities, 81 acres in areas subject to temporary disturbance during construction, and 1,211 acres in areas within the proposed floodplain. In addition, about 350 acres of land would serve as borrow areas that are likely to be under a Williamson Act contract.

Generally, land uses and improvements on lands enrolled in Williamson Act contracts are limited to commercial agriculture or uses determined to be compatible or incidental to commercial agriculture. Project infrastructure (e.g., the proposed levee system and other facilities) and habitat restoration areas are not considered compatible or incidental to agriculture. However, under Alternative A, agricultural activity (likely livestock grazing) would be allowed on lands within the proposed floodplain outside passive riparian and floodplain habitat restoration areas; livestock grazing would likely be consistent with Williamson Act contracts in effect on these lands.

Although conflicts with the Williamson Act contracts are relative to existing contract provisions and portions of the Project area may be considered a "compatible use" under the Williamson Act, for the purpose of this analysis it is assumed that Williamson Act contracts would be canceled during land acquisition. Further, there would be no effect on existing agricultural landowners with respect to additional tax burdens as they would no longer own the land.

When comparing Alternative A to existing conditions, impacts to Williamson Act contracts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative A to No-Action). In summary, long-term restoration activities that are not consistent with or incidental to commercial agriculture would likely conflict with provisions in existing Williamson Act contracts in place in the Project area; this impact is considered **significant**.

Mitigation Measure LU-3 (Alternative A): ***Preserve Agricultural Productivity of Designated Farmland to the Extent Possible.*** Refer to Mitigation Measure LU-1 (Alternative A). The same mitigation measure would apply to this impact. Project proponents will recognize and minimize adverse effects on agricultural lands to the extent practicable, including modification of construction practices. However, this mitigation measure would not fully avoid the conversion of agricultural land to non-agricultural uses, and there are no additional measures to fully mitigate the loss of farmland; therefore, this impact would be **significant and unavoidable**.

Impact LU-4 (Alternative A): ***Degradation of Agricultural Land Productivity due to Seepage***. Under Alternative A, groundwater modeling indicates that approximately 380 acres of land outside the levee alignments could be subject to groundwater levels less than 7 feet below ground surface and a 320-acre subset of that area would be subject to groundwater levels less than 5 feet below ground surface; refer to Impact GRW-2 (Alternative A) in Section 13.3.3. To the extent that these seepage-affected areas are in agricultural production, there would be potential effects on the agricultural productivity of the land due to waterlogging of crops. However, a range of seepage control measures are incorporated into the Project that would avoid or minimize seepage outside the levee alignments. Seepage control measures implemented in the Project area could include slurry walls, interceptor drains, seepage wells, seepage berms, land acquisition (fee title or seepage easements) and other measures (see Section 2.2.4). Accordingly, potential effects on agricultural production would be avoided or minimized.

Compared to the No-Action Alternative, where adverse effects to agricultural production in the Project area would be minimized by the Program's activities to control flow through the reach, Alternative A would have similar effects to agricultural productivity on lands potentially affected by seepage in the Project area because seepage effects would be minimized by seepage control measures included as Project actions.

Compared to existing conditions, where seepage effects occurred only during flood flow years in Reach 2B (instead of the potential for more frequent seepage issues with Restoration Flows), Alternative A could potentially have an adverse effect on agricultural productivity in the Project area due to the additional capacity for Restoration Flows which would occur every year. However, with the seepage-related measures integrated into the Project (see Section 2.2.4), this impact would be **less than significant**.

Impact LU-5 (Alternative A): ***Conflict with Applicable Land Use Plans Regarding Agricultural Lands***. Current and future land use in the Project area is guided by the zoning ordinances and general plans maintained by Fresno and Madera counties. As shown in Table 16-6 above, nearly all of the land in the Project area is zoned and designated for agricultural use. In addition, corresponding land use policies are generally intended to protect and promote agriculture in the region. Compared to No-Action, Alternative A would result in the long-term conversion of agricultural land to non-agricultural uses, namely open space and conservation uses. As a result, Alternative A would conflict with existing agricultural zoning, general plan designations, and associated agricultural land use policies of Fresno and Madera counties. Because the Project alternatives would not convert land to urban uses, future agricultural production in the Project area would not be precluded, but would be unlikely once project facilities are in place. Properties that are transferred into public ownership and used for Project purposes could be re-classified under applicable zoning ordinances and general plans to reflect land uses proposed under the Project. This change in use would require general plan amendments in both Fresno and Madera counties, and the re-zoning process would be subsequent to these amendments.

Compared to existing conditions, Alternative A would conflict with applicable land use plans maintained by Fresno and Madera counties based on the conversion of agricultural land to other land uses; this impact is considered **potentially significant**.

Mitigation Measure LU-5 (Alternative A): ***Notify County Planning Agencies of General Plan and Zoning Ordinance Inconsistencies.*** Project proponents will recognize and minimize adverse effects on agricultural land use and zoning by notifying Fresno and Madera County planning agencies of any inconsistencies in designations and applicable polices for affected areas. By notifying affected planning agencies of conflicts with current land use plans, the significant impact can be reduced to **less than significant**.

> **Implementation Action:** Fresno and Madera County planning agencies will be notified of any inconsistencies in designations and applicable polices for affected areas.

> **Location:** Agricultural lands within the Project area.

Effectiveness Criteria: Effectiveness will be based on whether updates can be made by county planning agencies.

Responsible Agency: Reclamation and CSLC.

Monitoring/Reporting Action: Notifications of zoning and land use plan inconsistencies will be confirmed with Reclamation project managers and CSLC monitors.

Timing: Formal notification of any zoning and/or land use plan inconsistencies would occur after project approval.

Impact LU-6 (Alternative A): ***Diminishment of Agricultural Production by Increased Disease***. Compared to No-Action, additional riparian vegetation and floodplain area along the river could affect the incidence of some orchard and vineyard diseases on adjacent land by serving as a source of causal organisms. Some riparian plants are alternative hosts for the causal organisms of some diseases of fruit and nut crops; for example, *Botryosphaeria dothedia* has been isolated from riparian plants. This bacterium can cause a shoot blight on pistachio and a canker on almonds, and it occurs on a number of crop, ornamental, and wild plants, causing diseases in some of them (Ma et al. 2001). Also, English walnut (*Juglans regia*) and stone fruits (*Prunus* species, including cherries and plums) can invade and persist in riparian vegetation and host disease organisms that also could affect the same species in orchards.

However, for several reasons, riparian vegetation would not substantially reduce agricultural productivity by increasing the incidence of disease. First, disease-causing organisms occur on a variety of fruit and nut crops, and these crops occupy much larger acreages in the Project area than the additional acreage of riparian host plants that would result from Alternative A. Therefore, riparian vegetation would likely be a less important source of disease-causing organisms than orchard and vineyard vegetation. Second, the incidence of disease is not solely or even primarily determined by the presence of causal organisms in the vicinity of an orchard or vineyard. Physical conditions (including weather), irrigation and other management practices, and susceptibility of crop cultivars and their rootstocks, are also important factors in the incidence of disease. Third, incidence of disease is only one of many factors affecting agricultural productivity. For these reasons, implementing Alternative A would not substantially reduce agricultural productivity by increasing disease.

When comparing Alternative A to existing conditions, impacts would be similar to those discussed in the preceding paragraphs (i.e., the comparison of Alternative A to No-Action). For the reasons described above, this impact would be **less than significant**.

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Similar to all of the Project alternatives, Alternative B proposes habitat restoration activities in conjunction with an expanded floodplain and widened levee alignments, as well as new Project facilities that promote fish passage through Reach 2B. Alternative B

has a relatively wider floodplain configuration that is located across agricultural land. Similar to Alternatives A and D, agricultural uses would be allowed within the proposed floodplain under Alternative B. Alternative B also includes a mixture of active and passive riparian and floodplain habitat restoration. Construction activity is expected to occur intermittently over an approximate 157-month timeframe.

Impact LU-1 (Alternative B): *Removal of Land from Agricultural Production*. Compared to No-Action, Alternative B would result in the removal of land from agricultural production in the Project area. As shown in Table 16-7 above, there are approximately 4,212 acres of land in agricultural production in the footprint of Alternative B. Of this total, about 1,032 acres would be subject to permanent loss of agricultural production, which includes the area underlying the proposed levee alignments and structures, the expanded floodplain, and borrow areas. In addition, another 42 acres of farmland would be temporarily disturbed during the 13-year construction period to accommodate features such as staging areas and access roads. Agricultural activity would be allowed on the floodplain within the proposed levee alignment (outside riparian habitat restoration areas) under Alternative B, up to 886 acres, however, because this area would be subject to frequent inundation, it is likely that agricultural activity would primarily be livestock grazing, a relatively low-value type of agriculture use compared to permanent and annual crop production that generate higher economic returns. Agricultural production on the remaining farmland within Alternative B, roughly 2,252 acres, would not be affected.

Table 16-10 shows agricultural impacts by crop type. The Project would affect both permanent and annual crops, with the greatest impacts expected on almonds, which account for nearly 35 percent of the agricultural land that would be taken out of production permanently. Other crops that would be taken out of production on a long-term basis include pistachios (15 percent of permanent agricultural losses), grapes (15 percent), row crops (10 percent), and vacant agricultural land (22 percent).

When comparing Alternative B to existing conditions (where there is no active habitat restoration in the Project area), impacts to agricultural land uses would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative B to No-Action). In summary, the Project would remove agricultural land from production over both the short term (i.e., during construction) and long term (i.e., into perpetuity) as lands are managed to meet the objectives and goals of the Settlement Agreement; this impact is considered **significant**.

Table 16-10.
Agricultural Effects by Crop Type, Alternative B

Crop Type	Type of Effect			
	Permanent Loss (acres)	Temporary Loss (acres)	Shift in Agricultural Activity (acres)	No Effect (acres)
Alfalfa	26	0	14	30
Almonds	402	1	259	1,302
Cotton	2	0	0	5
Grapes	107	20	186	310
Grazing	34	0	1	1
Other Row Crop	142	0	43	383
Palm	8	0	2	0
Pistachio	122	20	158	218
Agriculture-Vacant	190	0	224	3
Total	**1,032**	**42**	**886**	**2,252**

Mitigation Measure LU-1 (Alternative B): ***Preserve Agricultural Productivity of Designated Farmland to the Extent Possible.*** Refer to Mitigation Measure LU-1 (Alternative A). The same mitigation measure would apply to this impact. Project proponents will recognize and minimize adverse effects on agricultural lands to the extent practicable, including modification of construction practices. However, this mitigation measure would not fully avoid the conversion of agricultural land to non-agricultural uses, and there are no additional measures to fully mitigate the loss of farmland; therefore, this impact would be **significant and unavoidable**.

Impact LU-2 (Alternative B): ***Conversion of Designated Farmland to Non-Agricultural Uses***. Compared to No-Action, Alternative B would result in the conversion of designated Farmland in the Project area to non-agricultural uses (see Table 16-9), namely the permanent removal of 585 acres of Prime Farmland, 86 acres of Farmland of Statewide Importance, and 114 acres Unique Farmland from agricultural production to accommodate the proposed levees, floodplain restoration, and Project structures. Similar to all Project alternatives, an additional 350 acres of land would be required for borrow material to support construction activities; however, the exact location of the borrow areas is not known, although it is likely to occur on designated Farmland, which comprises about 88 percent of potential borrow areas under Alternative B. During construction, an additional 50 acres of designated Farmland would be temporarily taken out of production, but could return to active agriculture once the Project is complete. Lastly, approximately 786 acres of designated Farmland is located within the proposed floodplain, which would be available for agricultural activity (likely livestock grazing).

In cases where farmland remains undeveloped, the land would retain some of its agricultural value and long-term agricultural viability; however, because the proposed Reach 2B component of the Restoration Program is a long-term effort, these lands would

not likely return to active crop production and are considered to be converted to non-agricultural uses.

When comparing Alternative B to existing conditions, impacts to designated Farmland under the FMMP would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative B to No-Action). In summary, the Project would remove Prime Farmland, Farmland of Statewide Importance, and Unique Farmland from production over both the short- and long-term; this impact is considered **significant**.

Mitigation Measure LU-2 (Alternative B): ***Preserve Agricultural Productivity of Designated Farmland to the Extent Possible.*** Refer to Mitigation Measure LU-1 (Alternative A). The same mitigation measure would apply to this impact. Project proponents will recognize and minimize adverse effects on agricultural lands to the extent practicable, including modification of construction practices. However, this mitigation measure would not fully avoid the conversion of agricultural land to non-agricultural uses, and there are no additional measures to fully mitigate the loss of farmland; therefore, this impact would be **significant and unavoidable**.

Impact LU-3 (Alternative B): ***Conflict with Williamson Act Contracts***. Compared to No-Action, Alternative B would result in potential conflicts with Williamson Act contracts in effect on agricultural properties in the Project area. In total, approximately 172 acres under Williamson Act contract are located in areas underlying the proposed levee system and other Project facilities, 56 acres in areas subject to temporary disturbance during construction, and 1,543 acres in areas within the proposed floodplain. In addition, about 350 acres of land would serve as borrow areas that are likely to be under a Williamson Act contract.

Generally, land uses and improvements on lands enrolled in Williamson Act contracts are limited to commercial agriculture or uses determined to be compatible or incidental to commercial agriculture. Alternative B infrastructure and habitat restoration areas are not considered compatible or incidental to agriculture. However, under Alternative B, agricultural activity (likely livestock grazing) would be allowed on lands within the proposed floodplain outside riparian and floodplain habitat restoration areas; livestock grazing would likely be consistent with Williamson Act contracts in effect on these lands.

Although conflicts with Williamson Act contracts are relative to existing contract provisions and portions of the Project area may be considered a “compatible use” under the Williamson Act, for the purpose of this analysis it is assumed that Williamson Act contracts would be canceled during land acquisition. Further, there would be no effect on existing agricultural landowners with respect to additional tax burdens as they would no longer own the land.

When comparing Alternative B to existing conditions, impacts to Williamson Act contracts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative B to No-Action). In summary, long-term restoration activities that are not consistent or incidental to commercial agriculture would likely conflict with

Williamson Act contracts in place in the Project area; this impact is considered **significant**.

Mitigation Measure LU-3 (Alternative B): ***Preserve Agricultural Productivity of Designated Farmland to the Extent Possible.*** Refer to Mitigation Measure LU-1 (Alternative A). The same mitigation measure would apply to this impact. Project proponents will recognize and minimize adverse effects on agricultural lands to the extent practicable, including modification of construction practices. However, this mitigation measure would not fully avoid the conversion of agricultural land to non-agricultural uses, and there are no additional measures to fully mitigate the loss of farmland; therefore, this impact would be **significant and unavoidable**.

Impact LU-4 (Alternative B): *Degradation of Agricultural Land Productivity due to Seepage*. Under Alternative B, groundwater modeling indicates that outside the levee alignments, approximately 440 acres could be subject to groundwater levels less than 7 feet below ground surface and a 360-acre subset of that area would be subject to groundwater levels less than 5 feet below ground surface; refer to Impact GRW-2 (Alternative B) in Section 13.3.3. To the extent that the areas subject to seepage effects are in agricultural production, there would be potential effects on the agricultural productivity of the land due to waterlogging of crops. However, a range of seepage control measures incorporated into the Project would avoid or minimize seepage outside the levee alignments. Seepage control measures implemented in the Project area could include slurry walls, interceptor drains, seepage wells, seepage berms, land acquisition (fee title or seepage easements) and other measures (see Section 2.2.4). Accordingly, potential effects on agricultural production would be avoided or minimized.

Under No-Action conditions adverse effects to agricultural production in the Project area would be would be minimized by the Program's seepage control measures, such as activities to control flow through the reach. Compared to the No-Action Alternative, Alternative B would result in similar effects to agricultural productivity on lands potentially affected by seepage in the Project area because seepage effects would be minimized by seepage control measures included as Project actions.

Compared to existing conditions, where seepage effects occurred only during flood flow years in Reach 2B (instead of the potential for more frequent seepage issues with Restoration Flows), Alternative B could potentially have an adverse effect on agricultural productivity in the Project area due to the additional capacity for Restoration Flows which would occur every year. However, with the seepage-related measures integrated into the Project (see Section 2.2.4), this impact would be **less than significant**.

Impact LU-5 (Alternative B): *Conflict with Applicable Land Use Plans Regarding Agricultural Lands*. Under Alternative B, potential conflicts with applicable land use plans would generally be the same as those described for Alternative A; refer to Impact LU-5 (Alternative A) for details. Compared to existing conditions, Alternative B would conflict with applicable land use plans, including the Fresno and Madera County zoning ordinances and general plans based on the conversion of agricultural land to other land uses; this impact is considered **potentially significant**.

Mitigation Measure LU-5 (Alternative B): ***Notify County Planning Agencies of General Plan and Zoning Ordinance Inconsistencies.*** Refer to Mitigation Measure LU-5 (Alternative A). The same mitigation measure would apply to this impact. Project proponents will recognize and minimize adverse effects on agricultural land use and zoning by notifying Fresno and Madera County planning agencies of any inconsistencies in designations and applicable polices for affected areas. By notifying affected planning agencies of conflicts with current land use plans, the significant impact can be reduced to **less than significant**.

Impact LU-6 (Alternative B): ***Diminishment of Agricultural Production by Increased Disease***. Compared to No-Action, additional riparian vegetation and floodplain area along the river could affect the incidence of some orchard and vineyard diseases on adjacent land by serving as a source of causal organisms. However, the additional sources of causal organisms that could result from implementing Alternative B would not substantially reduce agricultural activity for several reasons: disease-causing organisms could already occur on a variety of widely planted fruit and nut crops in the Project area, the incidence of disease is not solely or even primarily determined by the presence of causal organisms in the vicinity of an orchard or vineyard, and incidence of disease is only one of many factors affecting agricultural productivity.

When comparing Alternative B to existing conditions, impacts would be similar to those discussed in the preceding paragraph (i.e., the comparison of Alternative B to No-Action). This impact would be **less than significant**.

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Similar to all of the Project alternatives, Alternative C proposes habitat restoration activities in conjunction with an expanded floodplain and widened levee alignments, as well as new Project facilities that promote fish passage through Reach 2B. Alternative C has a relatively narrow floodplain configuration. Unlike Alternatives A and D, agricultural uses would not be allowed within the proposed floodplain under Alternative C. Alternative C includes active riparian and floodplain habitat restoration. Construction activity is expected to occur intermittently over an approximate 133-month timeframe.

Impact LU-1 (Alternative C): ***Removal of Land from Agricultural Production***. Compared to No-Action, Alternative C would result in the removal of land from agricultural production in the Project area. As shown in Table 16-7 above, there are approximately 4,090 acres of land in agricultural production in the footprint of Alternative C. Of this total, about 1,567 acres would be subject to permanent loss of agricultural production, which includes the area underlying the proposed levee alignments and structures, the expanded floodplain, and borrow areas. In addition, another 73 acres of farmland would be temporarily disturbed during the 11-year construction period to accommodate features such as staging areas and access roads. Agricultural production on the remaining farmland within Alternative C, roughly 2,450 acres, would not be affected.

Table 16-11 shows agricultural effects by crop type. The Project would affect both permanent and annual crops, with the greatest impacts expected on almonds, which

account for nearly 35 percent of the agricultural land that would be taken out of production permanently. Other crops that would be taken out of production on a long-term basis include vacant agricultural land (27 percent of permanent agricultural losses), and pistachios (17 percent).

Table 16-11.
Agricultural Effects by Crop Type, Alternative C

Crop Type	Type of Effect			
	Permanent Loss (acres)	Temporary Loss (acres)	Shift in Agricultural Activity (acres)	No Effect (acres)
Alfalfa	28	3	0	37
Almonds	551	1	0	1,334
Cotton	2	7	0	5
Grapes	138	20	0	461
Grazing	38	0	0	1
Other Row Crop	129	20	0	367
Palm	10	0	0	0
Pistachio	266	20	0	232
Agriculture-Vacant	403	1	0	13
Total	**1,567**	**73**	**0**	**2,450**

When comparing Alternative C to existing conditions (where there is no active habitat restoration in the Project area), impacts to agricultural land uses would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative C to No-Action). In summary, the Project would remove agricultural land from production over both the short term (i.e., during construction) and long term (i.e., into perpetuity) as lands are managed to meet the objectives and goals of the Settlement Agreement; this impact is considered **significant**.

Mitigation Measure LU-1 (Alternative C): ***Preserve Agricultural Productivity of Designated Farmland to the Extent Possible.*** Refer to Mitigation Measure LU-1 (Alternative A). The same mitigation measure would apply to this impact. Project proponents will recognize and minimize adverse effects on agricultural lands to the extent practicable, including modification of construction practices. However, this mitigation measure would not fully avoid the conversion of agricultural land to non-agricultural uses, and there are no additional measures to fully mitigate the loss of farmland; therefore, this impact would be **significant and unavoidable**.

Impact LU-2 (Alternative C): ***Conversion of Designated Farmland to Non-Agricultural Uses***. Compared to No-Action, Alternative C would result in the conversion of designated Farmland in the Project area to non-agricultural uses (see Table 16-9), namely the permanent removal of 939 acres of Prime Farmland, 163 acres of Farmland of Statewide Importance, and 116 acres Unique Farmland from agricultural production to accommodate the proposed levees, floodplain restoration, and Project structures. Similar

to all Project alternatives, an additional 350 acres of land would be required for borrow material to support construction activities; however, the exact location of the borrow areas is not known, although it is likely to occur on Farmland, which comprises about 88 percent of potential borrow areas under Alternative C. Finally, during construction, an additional 81 acres of Farmland would be temporarily taken out of production, but could return to active agriculture once the Project is complete. In cases where farmland remains undeveloped (e.g., floodplain), the land would retain some of its agricultural value and long-term agricultural viability; however, because the proposed Reach 2B component of the Restoration Program is a long-term effort, these lands would not likely return to active crop production and are considered to be converted to non-agricultural uses.

When comparing Alternative C to existing conditions, impacts to designated farmland under the FMMP would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative C to No-Action). In summary, the Project would remove Prime Farmland, Farmland of Statewide Importance, and Unique Farmland from production over both the short and long term; this impact is considered **significant**.

Mitigation Measure LU-2 (Alternative C): ***Preserve Agricultural Productivity of Designated Farmland to the Extent Possible.*** Refer to Mitigation Measure LU-1 (Alternative A). The same mitigation measure would apply to this impact. Project proponents will recognize and minimize adverse effects on agricultural lands to the extent practicable, including modification of construction practices. However, this mitigation measure would not fully avoid the conversion of agricultural land to non-agricultural uses, and there are no additional measures to fully mitigate the loss of farmland; therefore, this impact would be **significant and unavoidable**.

Impact LU-3 (Alternative C): ***Conflict with Williamson Act Contracts***. Compared to No-Action, Alternative C would result in potential conflicts with Williamson Act contracts in effect on agricultural properties in the Project area. In total, approximately 173 acres under Williamson Act contract are located in areas underlying the proposed levee system and other Project facilities, 118 acres in areas subject to temporary disturbance during construction, and 1,211 acres in areas within the proposed floodplain. In addition, about 350 acres of land would serve as borrow areas that are likely to be under a Williamson Act contract.

Generally, land uses and improvements on lands enrolled in Williamson Act contracts are limited to commercial agriculture or uses determined to be compatible or incidental to commercial agriculture. However, Project infrastructure and habitat restoration areas are not considered compatible or incidental to agriculture.

Although conflicts with Williamson Act contracts are relative to existing contract provisions and portions of the Project area may be considered a “compatible use” under the Williamson Act, for the purpose of this analysis it is assumed that Williamson Act contracts would be canceled during land acquisition. Further, there would be no effect on existing agricultural landowners with respect to additional tax burdens.

When comparing Alternative C to existing conditions, impacts to Williamson Act contracts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative C to No-Action). In summary, long-term restoration activities that are not consistent or incidental to commercial agriculture would likely conflict with Williamson Act contracts in place in the Project area; this impact is considered **significant**.

Mitigation Measure LU-3 (Alternative C): ***Preserve Agricultural Productivity of Designated Farmland to the Extent Possible.*** Refer to Mitigation Measure LU-1 (Alternative A). The same mitigation measure would apply to this impact. Project proponents will recognize and minimize adverse effects on agricultural lands to the extent practicable, including modification of construction practices. However, this mitigation measure would not fully avoid the conversion of agricultural land to non-agricultural uses, and there are no additional measures to fully mitigate the loss of farmland; therefore, this impact would be **significant and unavoidable**.

Impact LU-4 (Alternative C): ***Degradation of Agricultural Land Productivity due to Seepage***. Under Alternative C, potential degradation of agricultural land productivity due to seepage would be the similar to that described under Alternative A as both alternatives propose a narrow floodplain; refer to Impact LU-4 (Alternative A) for details. Approximately 400 acres could be subject to groundwater levels less than 7 feet below ground surface and a 330-acre subset of that area would be subject to groundwater levels less than 5 feet below ground surface. Compared to the No-Action Alternative, where adverse effects to agricultural production in the Project area would be minimized by the Program's activities to control flow through the reach, Alternative C would have similar effects to agricultural productivity on lands potentially affected by seepage in the Project area because seepage effects would be minimized by seepage control measures included as Project actions.

Compared to existing conditions, where seepage effects occurred only during flood flow years in Reach 2B (instead of the potential for more frequent seepage issues with Restoration Flows), Alternative C could potentially have an adverse effect on agricultural productivity in the Project area due to the additional capacity for Restoration Flows which would occur every year. However, with the seepage-related measures integrated into the Project (see Section 2.2.4), this impact would be **less than significant**.

Impact LU-5 (Alternative C): ***Conflict with Applicable Land Use Plans Regarding Agricultural Lands***. Under Alternative C, potential conflicts with applicable land use plans would generally be the same as those described for Alternative A; refer to Impact LU-5 (Alternative A) for details. Compared to existing conditions, Alternative C would conflict with applicable land use plans, including the Fresno and Madera County zoning ordinances and general plans based on the conversion of agricultural land to other land uses; this impact is considered **potentially significant**.

Mitigation Measure LU-5 (Alternative C): ***Notify County Planning Agencies of General Plan and Zoning Ordinance Inconsistencies.*** Refer to Mitigation Measure LU-5 (Alternative A). The same mitigation measure would apply to this impact. Project

proponents will recognize and minimize adverse effects on agricultural land use and zoning by notifying Fresno and Madera County planning agencies of any inconsistencies in designations and applicable polices for affected areas. By notifying affected planning agencies of conflicts with current land use plans, the significant impact can be reduced to **less than significant**.

Impact LU-6 (Alternative C): ***Diminishment of Agricultural Production by Increased Disease***. Compared to No-Action, additional riparian vegetation and floodplain area along the river could affect the incidence of some orchard and vineyard diseases on adjacent land by serving as a source of causal organisms. However, the additional sources of causal organisms that could result from implementing Alternative C would not substantially reduce agricultural activity for several reasons: disease-causing organisms could already occur on a variety of widely planted fruit and nut crops in the Project area, the incidence of disease is not solely or even primarily determined by the presence of causal organisms in the vicinity of an orchard or vineyard, and incidence of disease is only one of many factors affecting agricultural productivity.

When comparing Alternative C to existing conditions, impacts would be similar to those discussed in the preceding paragraph (i.e., the comparison of Alternative C to No-Action). This impact would be **less than significant**.

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Similar to all of the Project alternatives, Alternative D proposes habitat restoration activities in conjunction with an expanded floodplain and widened levee alignments, as well as new Project facilities that promote fish passage through Reach 2B. Alternative D has a relatively wider floodplain configuration that is located across agricultural land. Alternative D includes passive riparian habitat restoration and farming in the floodplain. Similar to Alternatives A and B, agricultural uses that are suitable within the proposed floodplain would be allowed under Alternative D. Construction activity is expected to occur intermittently over an approximate 158-month timeframe.

Impact LU-1 (Alternative D): ***Removal of Land from Agricultural Production***. Compared to No-Action, Alternative D would result in the removal of land from agricultural production in the Project area. As shown in Table 16-7 above, there is approximately 4,208 acres of land in agricultural production in the footprint of Alternative D. Of this total, about 1,347 acres would be subject to permanent loss of agricultural production, which includes the area underlying the proposed levee alignments and structures, borrow areas, and passive riparian habitat restoration areas within the floodplain. In addition, another 69 acres of farmland would be temporarily disturbed during the 13-year construction period to accommodate features such as staging areas and access roads. Agricultural activity would be allowed on the floodplain within the proposed levee alignment (outside riparian habitat restoration areas) under Alternative D, up to 956 acres; however, because this area would be subject to frequent inundation, it is likely that agricultural activity would primarily be livestock grazing. Agricultural production on the remaining farmland within Alternative D, roughly 1,835 acres, would not be affected.

Table 16-12 shows agricultural effects by crop type. The Project would affect both permanent and annual crops, with the greatest impacts expected on almonds, which account for about 35 percent of the agricultural land that would be taken out of production permanently. Other crops that would be taken out of production on a long-term basis include row crops (18 percent of permanent agricultural losses), vacant agricultural land (15 percent), grapes (15 percent), and pistachios (11 percent).

Table 16-12.
Agricultural Effects by Crop Type, Alternative D

Crop Type	Type of Effect			
	Permanent Loss (acres)	Temporary Loss (acres)	Shift in Agricultural Activity (acres)	No Effect (acres)
Alfalfa	27	3	22	17
Almonds	493	1	308	1,167
Cotton	2	7	0	5
Grapes	205	20	71	323
Grazing	38	0	0	1
Other Row Crop	239	16	5	285
Palm	8	0	2	0
Pistachio	138	20	324	37
Agriculture-Vacant	197	1	225	0
Total	**1,347**	**69**	**956**	**1,835**

When comparing Alternative D to existing conditions (where there is no active habitat restoration in the Project area), impacts to agricultural land uses would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative D to No-Action). In summary, the Project would remove agricultural land from production over both the short term (i.e., during construction) and long term (i.e., into perpetuity) as lands are managed to meet the objective and goals of the Settlement Agreement; this impact is considered **significant**.

Mitigation Measure LU-1 (Alternative D): ***Preserve Agricultural Productivity of Designated Farmland to the Extent Possible.*** Refer to Mitigation Measure LU-1 (Alternative A). The same mitigation measure would apply to this impact. Project proponents will recognize and minimize adverse effects on agricultural lands to the extent practicable, including modification of construction practices. However, this mitigation measure would not fully avoid the conversion of agricultural land to non-agricultural uses, and there are no additional measures to fully mitigate the loss of farmland; therefore, this impact would be **significant and unavoidable**.

Impact LU-2 (Alternative D): ***Conversion of Designated Farmland to Non-Agricultural Uses***. Compared to No-Action, Alternative D would result in the conversion of designated Farmland in the Project area to non-agricultural uses (see Table 16-9).

Specifically, Alternative D would permanently remove 917 acres of Prime Farmland, 112 acres of Farmland of Statewide Importance, and 113 acres Unique Farmland from agricultural production to accommodate the proposed levees, floodplain restoration, and other Project structures. An additional 350 acres of land would be required for borrow material to support construction activities; however, the exact location of the borrow areas is not known, although it is likely to occur on Farmland, which comprises about 86 percent of potential borrow areas under Alternative D. During construction, another 77 acres of Farmland would be temporarily taken out of production, but could return to active agriculture once the Project is complete. Lastly, approximately 862 acres of Farmland is located within the proposed floodplain, which would be available for agricultural activity (likely livestock grazing) under Alternative D. With some of the Project features, particularly where farmland remains undeveloped, the land would retain some of its agricultural value and long-term agricultural viability; however, because the proposed Reach 2B component of the Restoration Program is a long-term effort, these lands would not likely return to active crop production and are considered to be converted to non-agricultural uses.

When comparing Alternative D to existing conditions, impacts to designated farmland under the FMMP would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative D to No-Action). In summary, the Project would remove Prime Farmland, Farmland of Statewide Importance, and Unique Farmland from production over both the short and long term; this impact is considered **significant**.

Mitigation Measure LU-2 (Alternative D): ***Preserve Agricultural Productivity of Designated Farmland to the Extent Possible.*** Refer to Mitigation Measure LU-1 (Alternative A). The same mitigation measure would apply to this impact. Project proponents will recognize and minimize adverse effects on agricultural lands to the extent practicable, including modification of construction practices. However, this mitigation measure would not fully avoid the conversion of agricultural land to non-agricultural uses, and there are no additional measures to fully mitigate the loss of farmland; therefore, this impact would be **significant and unavoidable**.

Impact LU-3 (Alternative D): ***Conflict with Williamson Act Contracts***. Compared to No-Action, implementation of Alternative D would result in potential conflicts with Williamson Act contracts in place on agricultural properties in the Project area. In total, approximately 551 acres under Williamson Act contract are located in areas underlying the proposed levee system and other Project facilities, 104 acres in areas subject to temporary disturbance during construction, and 1,635 acres within the proposed floodplain. In addition, about 350 acres of land would serve as borrow areas that are likely to be under a Williamson Act contract.

Generally, land uses and improvements on lands enrolled in Williamson Act contracts are limited to commercial agriculture or uses determined to be compatible or incidental to commercial agriculture. Project infrastructure (e.g., the proposed levee system and other facilities) and habitat restoration areas are not considered compatible or incidental to agriculture. However, under Alternative D, agricultural activity (likely livestock grazing) would be allowed on lands within the proposed floodplain (outside riparian and

floodplain habitat restoration areas); livestock grazing would likely be consistent with Williamson Act contracts in effect on these lands.

Although conflicts with the Williamson Act are relative to existing contract provisions and portions of the Project area may be considered a "compatible use" under the Williamson Act, for the purpose of this analysis it is assumed that Williamson Act contracts would be canceled during land acquisition. Further, there would be no effect on existing agricultural landowners with respect to additional tax burdens.

When comparing Alternative D to existing conditions, impacts to Williamson Act contracts would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative D to No-Action). In summary, long-term restoration activities that are not consistent or incidental to commercial agriculture would likely conflict with Williamson Act contracts in place in the Project area; this impact is considered **significant**.

Mitigation Measure LU-3 (Alternative D): ***Preserve Agricultural Productivity of Designated Farmland to the Extent Possible.*** Refer to Mitigation Measure LU-1 (Alternative A). The same mitigation measure would apply to this impact. Project proponents will recognize and minimize adverse effects on agricultural lands to the extent practicable, including modification of construction practices. However, this mitigation measure would not fully avoid the conversion of agricultural land to non-agricultural uses, and there are no additional measures to fully mitigate the loss of farmland; therefore, this impact would be **significant and unavoidable**.

Impact LU-4 (Alternative D): ***Degradation of Agricultural Land Productivity due to Seepage***. Under Alternative D, potential degradation of agricultural land productivity due to seepage would be similar to that described under Alternative B as both alternatives include a wider floodplain; refer to Impact LU-4 (Alternative B) for details. Approximately 400 acres could be subject to groundwater levels less than 7 feet below ground surface and a 330-acre subset of that area would be subject to groundwater levels less than 5 feet below ground surface. Compared to the No-Action Alternative, where adverse effects to agricultural production in the Project area would be minimized by the Program's activities to control flow through the reach, Alternative D would have similar effects to agricultural productivity on lands potentially affected by seepage in the Project area because seepage effects would be minimized by seepage control measures included as Project actions.

Compared to existing conditions, where seepage effects occurred only during flood flow years in Reach 2B (instead of the potential for more frequent seepage issues with Restoration Flows), Alternative D could potentially have an adverse effect on agricultural productivity in the Project area due to the additional capacity for Restoration Flows which would occur every year. However, with the seepage-related measures integrated into the Project (see Section 2.2.4), this impact would be **less than significant**.

Impact LU-5 (Alternative D): ***Conflict with Applicable Land Use Plans Regarding Agricultural Lands***. Under Alternative D, potential conflicts with applicable land use

plans would generally be the same as those described for Alternative A; refer to Impact LU-5 (Alternative A) for details. Compared to existing conditions, Alternative D would conflict with applicable land use plans, including the Fresno and Madera County zoning ordinances and general plans based on the conversion of agricultural land to other land uses; this impact is considered **potentially significant**.

Mitigation Measure LU-5 (Alternative D): ***Notify County Planning Agencies of General Plan and Zoning Ordinance Inconsistencies.*** Refer to Mitigation Measure LU-5 (Alternative A). The same mitigation measure would apply to this impact. Project proponents will recognize and minimize adverse effects on agricultural land use and zoning by notifying Fresno and Madera County planning agencies of any inconsistencies in designations and applicable polices for affected areas. By notifying affected planning agencies of conflicts with current land use plans, the significant impact can be reduced to **less than significant**.

Impact LU-6 (Alternative D): ***Diminishment of Agricultural Production by Increased Disease***. Compared to No-Action, additional riparian vegetation and floodplain area along the river could affect the incidence of some orchard and vineyard diseases on adjacent land by serving as a source of causal organisms. However, the additional sources of causal organisms that could result from implementing Alternative D would not substantially reduce agricultural activity for several reasons: disease-causing organisms could already occur on a variety of widely planted fruit and nut crops in the Project area, the incidence of disease is not solely or even primarily determined by the presence of causal organisms in the vicinity of an orchard or vineyard, and incidence of disease is only one of many factors affecting agricultural productivity.

When comparing Alternative D to existing conditions, impacts would be similar to those discussed in the preceding paragraph (i.e., the comparison of Alternative D to No-Action). This impact would be **less than significant**.

17.0 Noise and Vibration

The following sections provide information regarding the affected noise environment and include discussions regarding acoustics and noise measurements and relevant laws, ordinances, regulations, and standards related to environmental noise exposure in the vicinity of the Project. This chapter also describes environmental consequences and mitigation measures, as they pertain to implementation of the Project alternatives in the Project area.

17.1 Environmental Setting

As shown in Figure 17-1, the Project is located along the San Joaquin River, extending from below Mendota Dam to the Chowchilla Bifurcation Structure, and borders unincorporated portions of the Madera and Fresno counties.

17.1.1 Fundamentals of Acoustics

Noise is defined as unwanted sound. Sound levels are measured on a logarithmic scale in decibels (dB). The most common descriptor of sound and noise associated with community noise exposure is the A-weighted sound pressure level (dBA). It is defined as the sound pressure level in decibels as measured on a sound meter using the A-weighting filter network. The A-weighted frequency filter de-emphasizes the very low and very high frequency components of sound in a manner that simulates the frequency response of human hearing, and correlates well with people's group reactions to sound and environmental noise. All sound levels in this report are A-weighted. A-weighted sound pressure levels of typical sources of noise are shown in Table 17-1.

The ambient sound level is the existing sound level resulting from natural and mechanical sources and human activity considered normally present in a particular area. The ambient noise level is composed of the cumulative sum of all noise sources, both near and far. The background noise level generally describes the mixture of indistinguishable sounds from many sources without any one dominating sound. It is the noise level that exists in the absence of identifiable, sporadic, individual noise events such as those caused by individual automobile pass-bys, aircraft overflights, intermittent dog barking, etc.

Humans are better able to perceive relative change in noise levels than absolute noise levels. Potential responses of persons to changes in the noise environment are usually assessed by evaluating differences between the existing and total predicted future noise environments.

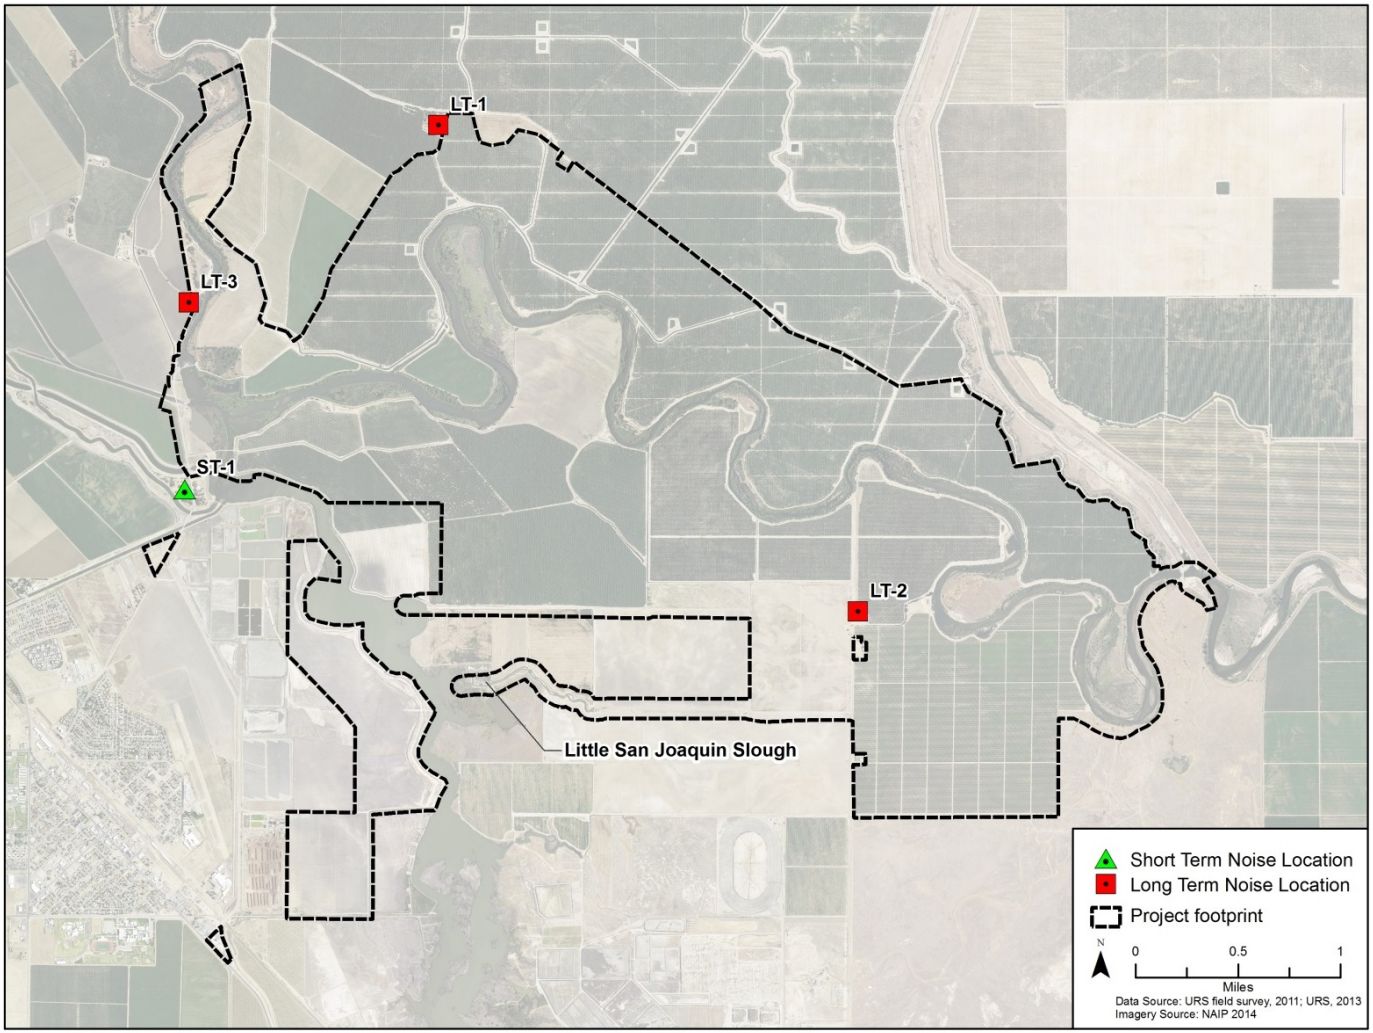

Figure 17-1.
Project Area and Ambient Noise Measurement Locations

Table 17-1.
Sound Levels of Typical Noise Sources and Noise Environments

Noise Source (at a given distance)	Scale of dBA Sound Levels	Noise Environment	Human Judgment of Noise Loudness (Relative to a Reference Loudness of 70 dBs*)
Commercial Jet Take-off (200 ft.)	120		Threshold of pain *32 times as loud
Pile Driver (50 ft.)	110	Rock Music Concert	*16 times as loud
Ambulance Siren (100 ft.) Newspaper Press (5 ft.) Power Lawn Mower (3 ft.)	100		Very loud *8 times as loud
Motorcycle (25 ft.) Propeller Plane Flyover (1000 ft.) Diesel Truck, 40 mph (50 ft.)	90	Boiler Room Printing Press Plant	*4 times as loud
Garbage Disposal (3 ft.)	80	High Urban Ambient Sound	*2 times as loud
Passenger Car, 65 mph (25 ft.) Vacuum Cleaner (10 ft.)	70		Moderately loud *70 decibels (Reference loudness)
Normal Conversation (5 ft.) Air Conditioning Unit (100 ft.)	60	Data Processing Center Department Store	*1/2 as loud
Light Traffic (100 ft.)	50	Private Business Office	*1/4 as loud
Bird Calls (distant)	40	Lower Limit of Urban Ambient Sound	Quiet *1/8 as loud
Soft. Whisper (5 ft.)	30	Quiet Bedroom	
	20	Recording Studio	Very quiet
	0		Threshold of hearing

Source: Harris 1991, Reherman et al. 2006, FTA 2006
Key:
dB = decibels
dBA = A-weighted decibels
ft. = feet
mph = miles per hour

The following relationships of perception and response to quantifiable noise changes are used as a basis for assessing potential effects of these changes in environmental noise level:

- Except in a carefully controlled laboratory condition, a change of 1 dBA is very difficult to perceive.
- In the outside environment, a 3 dBA change is considered just perceptible.
- An increase of 5 dBA is considered readily perceptible and could result in a change in community response.
- A 10 dBA increase is perceived as a doubling in loudness and would likely result in a widespread community response.

Because of the logarithmic nature of the dB unit, sound levels cannot be added or subtracted directly and are somewhat cumbersome to handle mathematically. However, some simple rules are useful in dealing with sound levels. First, if a sound's intensity is

doubled, the sound level increases by 3 dB, regardless of the initial sound level. For example, 60 dB + 60 dB = 63 dB, and 80 dB + 80 dB = 83 dB. Human perception is different. In terms of human response, a 3 dB change is just perceptible and a 10 dB change is perceived as a doubling or halving of sound level.

Because environmental noise varies with time, it is necessary to define certain measurement terms that are used to characterize this fluctuating quantity. The energy-average level over a specific period is defined as the Equivalent Sound Level (L_{eq}). The L_{eq} is the sound pressure level over a time interval that is equivalent to a perfectly constant sound pressure level containing the same acoustic energy over the same interval. Thus, L_{eq} includes all sporadic or transient events occurring during the time period.

In addition to the L_{eq} metric, the statistical distribution of measured sound levels is used to describe the range of noise levels measured during a given period. This metric is presented as $L_{N,}$ which is the sound level exceeded N percent of the time during a given measurement interval. For example, L_{10} (in dBA) is the sound level exceeded 10 percent of the time and this level is commonly used to represent loud transient events occurring during the measurement period. L_{50} is the sound level that is exceeded 50 percent of the time and represents the median sound level. L_{90} is the sound level exceeded 90 percent of the time and this level represents the background noise levels of the measurement. The maximum A-weighted noise level recorded for a single event is defined as L_{max}.

Other descriptors of noise are also commonly used to identify noise/land use compatibility guidelines and assist in the prediction of community reaction to adverse effects of environmental noise, including traffic-generated and industrial noise. These descriptors include the Day-Night Noise Level (L_{dn}); and in California, the Community Noise Equivalent Level (CNEL) descriptor is used. Each of these descriptors uses units of dBA. Both L_{dn} and CNEL noise metrics represent 24-hour periods and both apply a time-weighted factor designed to penalize noise events that occur during evening or nighttime hours, when relaxation and sleep disturbance is of more concern. The time-weighting adds a 5 dBA penalty to the hourly L_{eq} noise levels from 7:00 p.m. to 10:00 p.m. (evening period) and a 10 dBA penalty from 10:00 p.m. to 7:00 a.m. (nighttime period). For CNEL, daytime is defined as the time between 7:00 a.m. to 7:00 p.m., and for L_{dn} daytime is defined as the time between 7:00 a.m. to 10:00 p.m. The use of either the CNEL or L_{dn} noise metric is mandated by State guidelines for noise/land use compatibility planning purposes and are the predominant metrics used by local governments to describe noise environments within their jurisdictions.

Pressure waves of sound can be generated by vibrating structures and can induce vibration in structures. Vibration is caused by any force acting on a surface of a structure that causes it to move back and forth from its normal resting position. In contrast to airborne noise, ground-borne vibration is often not perceptible. For example, it is unusual for vibration from sources such as buses and trucks to be perceptible, even in locations close to major roads. Most perceptible indoor vibration is caused by sources within buildings such as operation of mechanical equipment, movement of people or slamming of doors. Typical outdoor sources of perceptible ground-borne vibration are construction equipment, steel-wheeled trains, and traffic on rough roads. Construction activities which

can cause perceptible vibrations include pile-driving and operating heavy earth-moving equipment.

In contrast to airborne noise, ground-borne vibration is not a phenomenon that most people experience every day. The background vibration velocity level in residential areas is usually 50 vibration decibels (VdB) or lower, well below the human threshold of perception which is around 65 VdB. Although the perceptibility threshold is about 65 VdB, human response to vibration is not usually significant unless the vibration exceeds 70 VdB (Federal Transit Administration [FTA] 2006).

17.1.2 Ambient Noise Measurements

The Project would be located along Reach 2B of the San Joaquin River, primarily in between Mendota Dam and the Chowchilla Bifurcation Structure, but also along a portion of Reach 3 below Mendota Dam. Nearby jurisdictions include the city of Mendota and unincorporated areas of Fresno and Madera counties.

Ambient noise measurements were conducted at four representative locations, of which three were 24-hour measurements and one was a short-term measurement. These locations are shown in Figure 17-1. The noise measurements were taken during the last week of December, between two major holidays, well after the growing season. Accordingly, these measurements provide a conservative estimate of ambient noise. The ambient noise levels varied throughout the Project area that would be used for project equipment staging, haul routes, and construction. Noise levels vary based on population density, distance to nearby traffic, aircraft flight patterns, nearby wildlife (for example, passing birds and insects), weather and other various conditions. During the noise measurements, the temperature was on average 48 degrees Fahrenheit with an average humidity of 50 percent. Winds ranged from calm to moderate with the highest recorded wind speed of 6 miles per hour. The weather was consistently clear throughout the entire noise measurement period.

All sound level meters were set to measure dBA noise levels at the slow meter response setting.[1] The sound level meters were placed in key locations that represented the ambient noise levels at representative locations. Each meter was calibrated before and after each measurement period. Certificates of calibration for the sound level meters and the calibrator used during the ambient noise level measurement survey can be found in Appendix 17-A. Locations where measurements were conducted are considered representative receivers of existing ambient noise levels within the Project area. Existing noise levels for the noise measurement sites are presented below. The field measurement data sheets can be found in Appendix 17-B.

LT-1

The noise-sensitive receiver located at LT-1 represents a cluster of single-family residences surrounded by agricultural land. The noise-sensitive receiver is located north of the San Joaquin River in an unincorporated area of Madera County. The sound level meter was mounted to a power pole near the intersection of Eastside Drive and Drive 10

[1] The slow meter response setting is a setting where the meter detects sound level changes over at least one second in duration. It is used for evaluating continuous and average noise levels.

½ Road. Table 17-2 lists the results of the long-term measurement conducted at measurement site LT-1. The primary noise sources in the area consisted of traffic and nearby farming activity. The average daytime ambient noise level (L_{eq}) was 49.9 dBA and hourly L_{eq} values ranged from 36.2 to 57.2 dBA. The average evening ambient noise level (L_{eq}) was 49.6 dBA and hourly L_{eq} values ranged from 44.1 to 52 dBA. The average nighttime ambient noise level (L_{eq}) was 45.3 dBA and hourly L_{eq} values ranged from 36.6 to 49.1 dBA. The difference between the daytime and nighttime L_{eq} is 4.6 dBA, which is to be expected for an isolated environment with very little human activity. The ambient noise level would be equivalent to refrigerator humming or a quiet office setting.

Table 17-2.
24-hour Sound Level Measurement at LT-1 (dBA)

Date	Time (Hour-Starting)	L_{eq}	L_{max}	L_{10}	L_{50}	L_{90}	L_{min}
12/28/2011	10:00:00	44.0	69.3	42.9	39.5	36.7	34.0
12/28/2011	11:00:00	57.2	82.6	47.1	38.1	34.2	32.2
12/28/2011	12:00:00	55.4	80.5	50.1	36.7	32.3	30.6
12/28/2011	13:00:00	48.2	71.4	47.7	38.5	33.8	30.8
12/28/2011	14:00:00	36.2	49.8	38.9	34.8	31.0	28.2
12/28/2011	15:00:00	43.1	70.5	42.1	35.6	31.2	27.0

12/29/2011	8:00:00	44.0	60.7	46.2	42.3	39.4	36.0
12/29/2011	9:00:00	46.4	74.7	42.4	38.7	36.3	34.8

Notes:

Measurements conducted on December 28 and 29, 2011. Measurement Location: N 36° 48' 22.4", W 120° 20' 59.3."

24-hour L_{eq} = 48.7 dBA; CNEL = 53.3 dBA; Daytime L_{eq} = 49.9 dBA; Evening L_{eq} = 49.6 dBA; Nighttime L_{eq} = 45.3 dBA

Key:

dBA = A-weighted decibel
L_{eq} = equivalent sound level
L_{max} = maximum sound level
L_{min} = minimum sound level
L_{10} = sound level exceeded 10 percent of the time
L_{50} = sound level exceeded 50 percent of the time
L_{90} = sound level exceeded 90 percent of the time

LT-2

The noise-sensitive receiver located at LT-2 represents a single-family residence on San Mateo Road south of the San Joaquin River in Fresno County. The primary noise sources in the area consisted of traffic, farming activities and barking dogs. Table 17-3 lists the results of the long-term measurement conducted at measurement site LT-2. The average daytime ambient noise level (L_{eq}) was 56.5 dBA and hourly L_{eq} values ranged from 42.8 to 60.5 dBA. The average evening ambient noise level (L_{eq}) was 47.1 dBA and hourly L_{eq} values ranged from 40.3 to 49.9 dBA. The average nighttime ambient noise level (L_{eq}) was 45.6 dBA and hourly L_{eq} values ranged from 27.9 to 52.1 dBA. The difference between the daytime and nighttime L_{eq} is 10.9 dBA, which is due to farming equipment activities and barking dogs during daytime hours. The ambient noise level in this area is equivalent to an office setting or a quiet room.

Table 17-3.
24-hour Sound Level Measurement at LT-2 (dBA)

Date	Time (Hour-Starting)	L_{eq}	L_{max}	L_{10}	L_{50}	L_{90}	L_{min}

24-hour L_{eq} = 53.9 dBA; CNEL = 55.8 dBA; Daytime L_{eq} = 56.5 dBA; Evening L_{eq} = 47.1 dBA; Nighttime L_{eq} = 45.6 dB

Key:
dBA = A-weighted decibel
L_{eq} = equivalent sound level
L_{max} = maximum sound level
L_{min} = minimum sound level
L_{10} = sound level exceeded 10 percent of the time
L_{50} = sound level exceeded 50 percent of the time
L_{90} = sound level exceeded 90 percent of the time

LT-3

The noise-sensitive receiver located at LT-3 represents a single-family residence at the north end of Bass Avenue. The noise-sensitive receiver is located north of the city of Mendota within an unincorporated area of Fresno County and on the northwest side of the San Joaquin River. The sound level meter was mounted on a tree at the north end of Bass Avenue. The primary noise sources in the area consisted of local traffic at the homes and barking dogs. Table 17-4 lists the results of the long-term measurement conducted at measurement site LT-3.

Table 17-4.
24-hour Sound Level Measurement at LT-3 (dBA)

Date	Time (Hour-Starting)	L_{eq}	L_{max}	L_{10}	L_{50}	L_{90}	L_{min}

12/29/2011	7:00:00	41.0	62.7	43.3	37.4	34.6	32.5
12/29/2011	8:00:00	42.6	70.1	43.0	39.6	36.7	35.1
12/29/2011	9:00:00	38.7	50.9	40.7	37.7	35.9	34.4

Notes:

Measurements conducted on December 28 and 29, 2011. Measurement Location: N 36° 47' 32.6", W 120° 22' 18.5."

24-hour L_{eq} = 38.5 dBA; CNEL = 41.2 dBA; Daytime L_{eq} = 40.9 dBA; Evening L_{eq} = 33.6 dBA; Nighttime L_{eq} = 32.5 dBA

Key:

dBA = A-weighted decibel

L_{eq} = equivalent sound level

L_{max} = maximum sound level

L_{min} = minimum sound level

L_{10} = sound level exceeded 10 percent of the time

L_{50} = sound level exceeded 50 percent of the time

L_{90} = sound level exceeded 90 percent of the time

The average daytime ambient noise level (L_{eq}) was 40.9 dBA and hourly L_{eq} values ranged from 35.6 to 46.4 dBA. The average evening ambient noise level (L_{eq}) was 33.6 dBA and hourly L_{eq} values ranged from 31.2 to 34.8 dBA. The average nighttime ambient noise level (L_{eq}) was 32.5 dBA and hourly L_{eq} values ranged from 27.4 to 36.8 dBA. The difference between the daytime and nighttime L_{eq} is 8.4 dBA, which is to be expected for an isolated environment with limited human activity. This very quiet ambient noise level in this area is equivalent to whispering or a faint hum from a refrigerator.

ST-1

The noise-sensitive receiver located at ST-1 represents the Mendota Pool Park located within the city of Mendota in an unincorporated area of Fresno County. The sound level meter was mounted to a tripod for daytime, evening and nighttime measurements. The primary noise sources in the park consisted of passing traffic on Bass Road, traffic driving through the park, birds chirping, distant traffic and a distant power plant during the evening and nighttime measurement periods. Table 17-5 lists the results of the short-term measurement conducted at measurement site ST-1. The average daytime ambient noise level (L_{eq}) was found to be 41.3 dBA. The average evening ambient noise level (L_{eq}) was found to be 38.6 dBA. The average nighttime ambient noise level (L_{eq}) was found to be 35.4 dBA. The difference between the daytime and nighttime L_{eq} is 5.9 dBA, which is to be expected for an isolated environment with limited human activity. This very quiet ambient noise level in this area is equivalent to whispering or a refrigerator humming.

Table 17-5.
Short-Term Sound Level Measurements at ST-1 (dBA)

Date	Start Time	End Time	L_{eq}	L_{10}	L_{50}	L_{90}
12/28/2011	10:30:00	12:30:00	41.3	43.6	36.1	31.3
12/28/2011	20:00:00	22:00:00	38.6	35.2	31.1	27.5
12/28/2011	23:00:00	1:00:00	35.4	36.3	33.2	30.8

Notes:

Measurements conducted on December 28 and 29, 2011. Measurement Location: N 36° 46' 43.6", W 120° 22' 23.7."

24-hour L_{eq} = 39.0 dBA; CNEL = 43.7 dBA; Daytime L_{eq} = 41.3 dBA; Evening L_{eq} = 38.6 dBA; Nighttime L_{eq} = 35.4 dBA

Key:

dBA = A-weighted decibel

L_{eq} = equivalent sound level

L_{10} = sound level exceeded 10 percent of the time

L_{50} = sound level exceeded 50 percent of the time

L_{90} = sound level exceeded 90 percent of the time

17.2 Regulatory Setting

Applicable laws, ordinances, regulations or standards and noise guidelines are used at the local level for planning purposes. Local noise guidelines are often based on the broader guidelines of State and Federal agencies and many are implemented as enforceable noise ordinances. Laws, ordinances, regulations or standards that are applicable to the Project are presented in this section.

17.2.1 Federal

There are a number of laws and guidelines at the Federal level that direct the consideration of a broad range of noise and vibration issues. For perspective, several of the more significant noise-related Federal regulations and guidelines are provided below:

Noise Control Act of 1972 (42 United States Code [USC] 4910)

This Act establishes a national policy to promote an environment free from noise that jeopardizes human health and welfare. To accomplish this, the Act establishes a means for the coordination of Federal research and activities in noise control, authorizes the establishment of Federal noise emissions standards for products distributed in commerce, and provides information to the public respecting the noise emission and noise reduction characteristics of such products.

U.S. Environmental Protection Agency (EPA) Levels Document

In response to a Federal mandate, EPA provided recommendations in *Information on Levels of Environmental Noise Requisite to Protect Health and Welfare with an Adequate Margin of Safety,* NTIS 550\9-74-004 (EPA 1974). The guidance in this document, commonly referenced as the "Levels Document," establishes an L_{dn} of 55 dBA as the requisite level, with an adequate margin of safety, for areas of outdoor uses including residences and recreation areas. This document does not constitute EPA regulations or standards but identifies safe levels of environmental noise exposure without consideration for methods of achieving these levels or other potentially relevant considerations. It is intended to "provide State and local governments as well as the Federal government and the private sector with an informational point of departure for the purpose of decision making." EPA is careful to stress that the recommendations contain a factor of safety and do not consider technical or economic feasibility issues and therefore should not be construed as standards or regulations. This document is generally considered the most relevant Federal guidelines applicable to community noise exposure.

Federal Highway Administration Noise Abatement Procedures (23 Code of Federal Regulations [CFR] Part 772)

The purpose of 23 CFR Part 772 is to provide procedures for noise studies and noise abatement measures to help protect public health and welfare, to supply noise abatement criteria, and to establish requirements for information to be given to local officials for use in the planning and design of highways. It establishes five categories of noise sensitive receptors and prescribes the use of the hourly L_{eq} as the criterion metric for evaluating traffic noise impacts.

Occupational Safety and Health Administration (OSHA) Occupational Noise Exposure; Hearing Conservation Amendment (Federal Register [FR] 48 (46), 9738 – 9785 (1983).

The OSHA standard stipulates that protection against the effects of noise exposure are required for employees when sound levels exceed 90 dBA over an 8-hour exposure period. Protection would consist of feasible administrative or engineering controls. If such controls fail to reduce sound levels to within acceptable levels, personal protective equipment would be provided and used to reduce exposure of the employee. Additionally, a Hearing Conservation Program must be instituted by the employers

whenever employee noise exposure equals or exceeds the action level of an 8-hour time-weighted average sound level of 85 dBA. The Hearing Conservation Program requirements consist of periodic area and personal noise monitoring, performance and evaluation of audiograms, provision of hearing protection, annual employee training, and record keeping.

Federal Transit Administration

To address the human response to groundborne vibration, FTA has set forth guidelines for criteria related to maximum acceptable vibration for different types of land uses. For frequent events, these include 65 VdB for land uses where low ambient vibration is essential for interior operations (e.g., hospitals, high-technology manufacturing, and laboratory facilities), 72 VdB for residential uses and buildings where people normally sleep, and 75 VdB for institutional land uses with primarily daytime operations (e.g., schools, churches, clinics, and offices) (FTA 2006).

Standards have also been established to address the potential for groundborne vibration to cause structural damage to buildings. These standards were developed by the Committee of Hearing, Bioacoustics, and Biomechanics at the request of EPA (FTA 2006). For fragile structures, the Committee of Hearing, Bioacoustics, and Biomechanics recommends a maximum limit of 0.25 in/sec peak particle velocity (FTA 2006). Peak particle velocity is a measure of the intensity of ground vibration, specifically the time rate of change of the amplitude of ground vibration.

17.2.2 State of California

The State establishes noise compatibility guidelines. These guidelines are used to ensure compatible noise levels at various noise sensitive land uses from transportation related noise sources related to new projects. Land use categories and their corresponding maximum allowable noise exposure levels (in terms of CNEL) can be found in Table 17-6. As shown in Table 17-6, the maximum allowable noise exposure level for residential land use is 60 dBA CNEL.

Table 17-6.
Land Use Compatibility of Community Noise Environments

17.2.3 Regional and Local

Fresno County

Noise level limits associated with fixed noise sources are found in the Fresno County Noise Ordinance. These limits are presented in Table 17-7. The noise standards found in Table 17-7 applies to all residences, schools, hospitals, churches, and public libraries. Table 17-7 lists the exterior noise standards by time of exposure within a one-hour time period. A 50 dBA L_{50} is the daytime baseline criterion noise level and a 45 dBA L_{50} is the nighttime baseline noise criterion. Impulsive, or pure tone, noise is penalized by a reduction of 5 dBA for each noise standard. In Fresno County, construction noise is exempt from local noise standards on weekdays from 6:00 a.m. to 9:00 p.m. and on Saturday and Sunday from 7:00 a.m. to 5:00 p.m.

Table 17-7.
Fresno County Exterior Noise Level Standards for Noise-Sensitive Land Uses Affected by Non-Transportation Noise Sources (dBA)

Cumulative Number of Minutes in Any 1-Hour Period	Corresponding $L_{percent}$	Daytime (7:00 a.m. to 10:00 p.m.)	Nighttime (10:00 p.m. to 7:00 a.m.)
30	L_{50}	50	45
15	L_{25}	55	50
5	$L_{8.3}$	60	55
1	$L_{1.7}$	65	60
0	-	70	65

Source: Fresno County 1978
Key: dBA = A-weighted decibels

Madera County

Madera County establishes local exterior noise level limits from non-transportation noise sources in the Madera County Noise Element. Noise level limits associated with fixed noise sources are found in Table 17-8. The noise standards found in Table 17-8 apply to all residences, transient lodging, churches, meeting halls, schools, theaters, auditoriums, music halls, hospitals, nursing homes, office buildings, museums, playgrounds, parks, and public libraries. A 50 dBA L_{eq} is the daytime baseline criterion noise level and a 45 dBA L_{eq} is the nighttime baseline noise criterion. Impulsive, or pure tone, noise is penalized by a reduction of 5 dBA for each noise standard. In Madera County, construction noise is exempt from local noise standards on weekdays from 7:00 a.m. to 7:00 p.m. and on Saturday from 9:00 a.m. to 5:00 p.m. Construction noise is not exempt from noise standards on Sundays.

Table 17-8.
Madera County Exterior Noise Level Standards for Noise-Sensitive Land Uses Affected by Non-Transportation Noise Sources (dBA)

Noise Level Descriptor	Daytime (7:00 a.m. to 10:00 p.m.)	Nighttime (10:00 p.m. to 7:00 a.m.)
Hourly Average (L_{eq}), dBA	50	45
Maximum (L_{max}), dBA	70	65

Source: Madera County 1995
Key: dBA = A-weighted decibels

City of Mendota

The city of Mendota (2009) establishes local exterior noise level limits in the city of Mendota Noise Element. Noise level limits associated with fixed noise sources are found in Table 17-9. The noise standards found in Table 17-9 apply to all residences, transient lodging, churches, meeting halls, schools, theaters, auditoriums, music halls, hospitals, nursing homes, office buildings, museums, playgrounds, parks, and public libraries. A 55 dBA L_{eq} is the daytime baseline criterion noise level, a 50 dBA L_{eq} is the evening baseline criterion noise level, and a 45 dBA L_{eq} is the nighttime baseline noise criterion. Impulsive, or pure tone, noise is penalized by a reduction of 5 dBA for each noise standard.

The city of Mendota's (2010) Excessive Noise Standard states that between the hours of 10:00 p.m. and 7:00 a.m., operation of equipment or performance of any outside construction or repair work on buildings, structures or projects or operations of construction type device is not allowed if the activity takes place within 500 feet of any residential zone. Noise generated by construction activities are required to be limited to the daytime hours between 7:00 a.m. and 7:00 p.m. and are prohibited on Federal holidays. If nighttime construction activities are necessary, the city of Mendota's Public Works director would need to be contacted.

17.3 Environmental Consequences and Mitigation Measures

17.3.1 Impact Assessment Methodology

This section describes the methodology used to determine potential noise impacts generated by noise and vibration associated with construction activities, increased off-site traffic, and operational activities related to the Project. The noise impact assessment is based on four potential Project Alternatives: Alternative A (Compact Alignment Bypass with Narrow Floodplain and South Canal), Alternative B (Compact Alignment Bypass with Consensus-Based Floodplain and Bifurcation Structure), Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal) and Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal).

Construction Noise Related Effects on Sensitive Receivers Noise levels generated by construction activities associated with Alternatives A, B, C and D at nearby noise-sensitive receptors were evaluated using the FTA's Transit Noise and Vibration Impact Assessment (FTA 2006). Noise levels for each type of construction equipment that would be used throughout the duration of construction for the Project were derived from the Federal Highway Administration's (FHWA's) Road Construction Noise Model. Table 17-10 lists the noise emission levels at a distance of 50 feet from the source for each type of construction equipment that would be used during the construction phase of the Project.

Table 17-10.
Construction Equipment Noise Emission Levels

Equipment	Typical Noise Level (dBA) 50 feet from Source

Water Truck (4,000 Gal)	76

Note: Construction equipment inventory was developed by the California Department of Water Resources for the appraisal-level designs.

Emission levels from the FHWA Road Construction Noise Model and usage factors for construction equipment were used in order to calculate an L_{eq} for the loudest construction activity within each designated group for all four Project alternatives. If the specific equipment was not found in the Road Construction Noise Model, then the emission level of similar equipment was used.

The following equation calculates the resulting L_{eq} at a sensitive receiver for an individual piece of construction equipment. This formula is used to adjust the noise level generated by the individual piece of construction equipment based on the estimated time that it is planned to be used during an hour.

$$L_{eq}(equip) = E.L. + 10\log(U.F.)$$

where:

$L_{eq}(equip)$ = L_{eq} at a receiver resulting from the operation of a single piece of equipment over a specified time period.

E.L .= noise emission level of the particular piece of equipment at a reference distance of 50 feet (found in Table 17-10).

U.F. = usage factor that accounts for the fraction of time that the equipment is in use over the specified period of time.

The FTA's General Assessment for construction noise assumes that the two loudest pieces of equipment are operating simultaneously for each construction activity. The associated noise level, in terms of L_{eq}, was calculated for each type of construction activity, and the distance to the daytime 50 dBA L_{eq} and nighttime 45 dBA L_{eq} noise contours was derived. Local noise standards are based on L_{50} and L_{eq} noise standards. In order to generate a conservative estimate for potential noise impacts, the L_{eq} noise standards were used as the local noise standard threshold for noise impacts as a worst-case scenario because an L_{eq} noise standard is more stringent and it assumes a steady-state noise level from construction equipment. Appendix 17-C lists the associated noise levels for each construction activity, in addition to listing the distances to the nighttime 45 dBA and daytime 50 dBA L_{eq} noise contours.

Additional modeled noise-sensitive receivers were added to the noise model where ambient noise level measurements were not conducted. Figure 17-2 depicts the location of all ambient noise measurement locations in addition to the modeled receiver locations. There are four residences located approximately 500 feet west of LT-1. These four residences are identified as Modeled Receiver 4 (R-4) and referenced as such throughout the analysis. There are several homes located near LT-2. R-5 is a single-family home located near Little San Joaquin Slough. R-6 is a single-family home located approximately 3,500 feet south of LT-2 along San Mateo Avenue. R-7 is two single-family homes located approximately 1,000 feet south of LT-2 along San Mateo Avenue. There are also several homes located near LT-3. R-2 is a group of homes located approximately 3,700 feet northwest of LT-3. R-3 is a group of homes located approximately 2,000 feet northwest of LT-3. R-1 is a group of homes located along Bass Avenue.

Due to the size of the Project footprint, the amount of equipment, and the non-stationary nature of the construction activities, it is difficult to estimate an exact location where construction equipment would be situated. In order to determine the minimum allowable distance to each construction activity for each noise-sensitive receiver, the maximum allowable hourly L_{eq} values for each construction activity for each Alternative were calculated. It was also assumed for the purpose of calculating an hourly L_{eq} noise level for each construction activity that the two loudest pieces of equipment were operating simultaneously. These noise levels were then used to calculate the distances to the daytime 50 dBA L_{eq} and nighttime 45 dBA L_{eq} noise contours.

The potential for noise to impact wildlife is addressed in Section 7.0, Biological Resources–Wildlife.

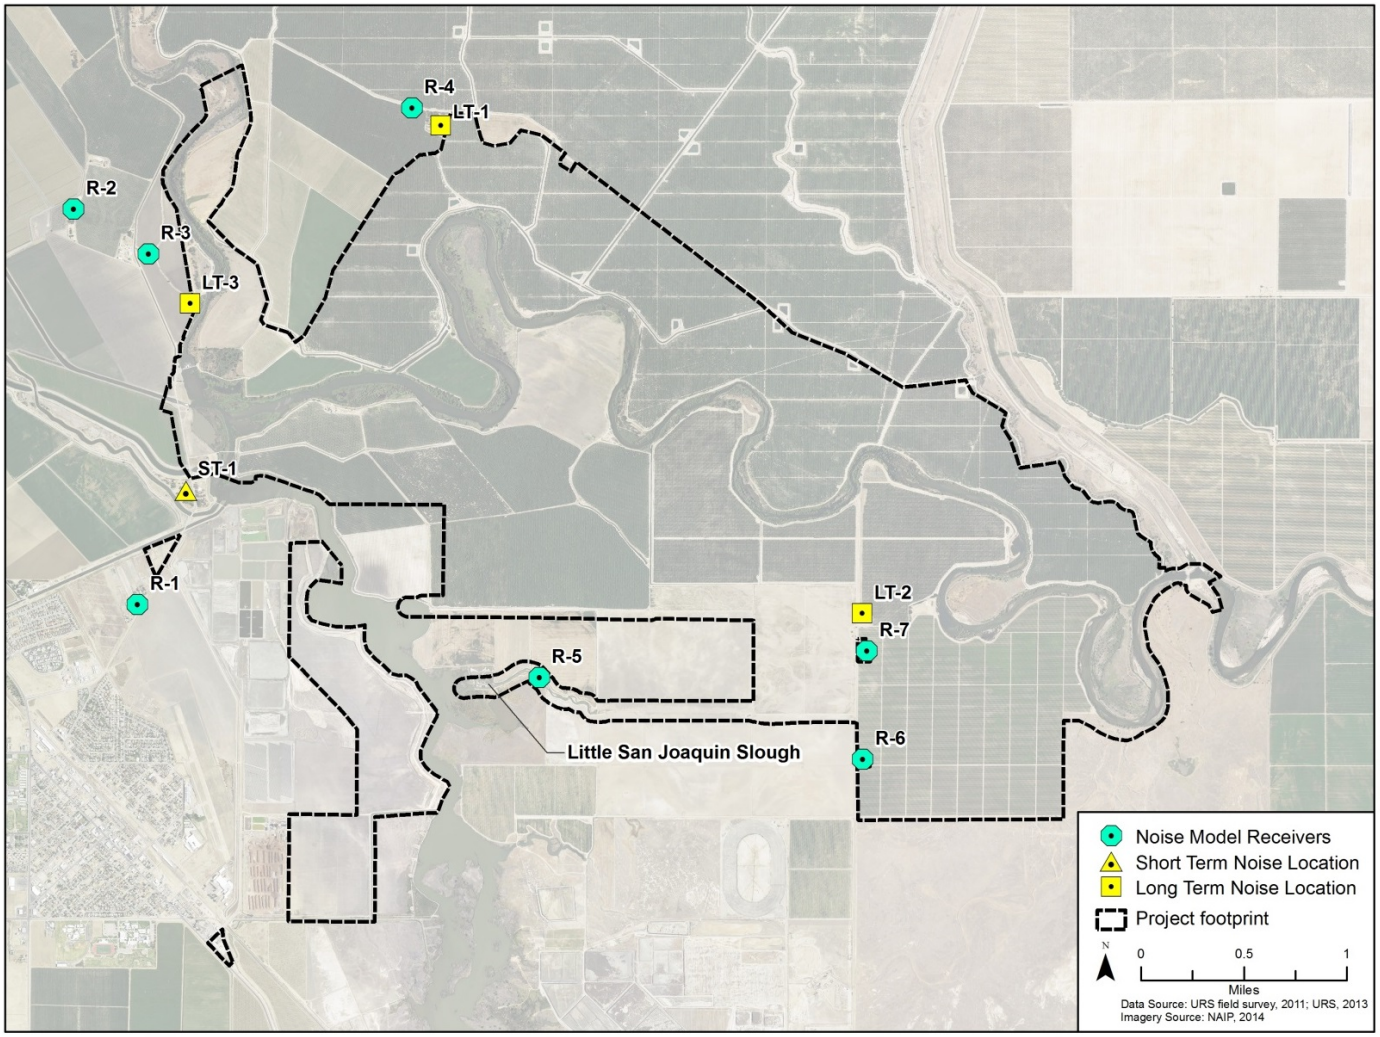

Figure 17-2.
Ambient Noise Level Measurement and Modeled Receiver Locations

Construction Vibration Related Effects on Sensitive Receptors

Table 17-11 is reproduced from Table 12-2 of the FTA Manual (2006) and it lists vibration source levels for typical construction equipment. Impact pile driving activities would be conducted during the construction of Project components and the vibration source level listed for impact pile drivers (104 VdB at a distance of 25 feet) is the reference level that is used for estimating potential annoyance generated by pile driving activities.

Table 17-11.
Vibration Source Levels for Construction Equipment

Equipment		Peak particle velocity at 25 ft (in/sec)	Approximate RMS vibration velocity at 25 ft (VdB)
Pile Driver (impact)	upper range	1.518	112
	typical	0.644	104
Pile Driver (sonic)	upper range	0.734	105
	typical	0.170	93
Clam shovel drop (slurry wall)		0.202	94
Hydromill (slurry wall)	in soil	0.008	66
	in rock	0.017	75
Vibratory Roller		0.210	94
Hoe Ram		0.089	87
Large bulldozer		0.089	87
Caisson drilling		0.089	87
Loaded trucks		0.076	86
Jackhammer		0.035	79
Small bulldozer		0.003	58

Source: FTA 2006

Key:
RMS = root mean square velocity
VdB = vibration decibels

It is assumed, as a worst-case scenario for ground-borne vibration levels, that more than 70 vibration events would be conducted per day during pile driving activities. Utilizing this assumption results in a vibration standard of 72 VdB at residences and buildings where people normally sleep. Using the reference level of 104 VdB at a distance of 25 feet, the distance to 72 VdB was be calculated. Vibration-sensitive receivers within this calculated distance may be subjected to vibration levels that could cause annoyance and have an adverse effect.

Off-site Vehicular Traffic Noise Effects due to Construction-Related Trips

Acoustic calculations were performed for noise generated by traffic during construction activities related to Project alternatives. The access routes to the Project area were assumed to be along Bass Avenue, San Mateo Avenue, State Route (SR)-180, and SR-33 (north and south of the SR-180/33 junction).

Average daily traffic (ADT) volumes and traffic mixes for each roadway segment were taken from the California Department of Transportation (Caltrans) Operational Traffic Data Branch during the year 2011, which was used to represent existing conditions (Caltrans 2011).[2] An estimated 2035 ADT was used to represent the No-Action Alternative. A traffic growth rate of 1 percent per year starting from 2011 was used to estimate the 2035 ADT.

For Alternatives A through D, it was assumed that: (1) all construction workers going to the Project site would originate from the construction office, which is located on the southwest corner of the Project area; (2) construction workers would generate 200 trips (100 round trips) going to and from the construction office each day throughout the full duration of the construction phase of the Project; and (3) workers would be traveling along Bass Avenue, SR-180 and SR-33 (north and south of the SR-180/33 junction). During the construction phase of the Project, heavy trucks would haul off-site materials to and from the stockpile staging area located on the southeast corner of the Project area along San Mateo Avenue. The ADT for heavy trucks was derived using construction schedules and estimates of truck trips developed by California Department of Water Resources (DWR) for the appraisal-level designs.

The traffic noise prediction equations derived by the FHWA were used to estimate the CNEL for existing conditions, the No-Action Alternative and Alternatives A through D at 50 feet from each respective roadway segment. The estimated CNEL for each alternative was individually compared to the No-Action Alternative and existing conditions, respectively, to determine the change in CNEL for each alternative. For this traffic noise analysis, a change of 5 dBA CNEL at 50 feet from a roadway segment is considered to be an impact.

Noise Effects due to Operation and Maintenance Activities

Increases in Project-related ADT volumes were estimated for operational and maintenance activities to evaluate potential Project-related changes in traffic noise. Vehicle traffic would be associated with operation and maintenance activities such as inspection and adjustment of water control structure gates, inspection and cleaning of fish screens, fish barriers, and fish ladders, inspection of gates at Mendota Dam, installation and removal of flashboards at Mendota Dam, sediment removal from channels and canals, and removal of debris from culverts. Operation and maintenance-related traffic were compared to ambient traffic along access routes leading into the Project area to assess effect on nearby noise sensitive receivers.

17.3.2 Significance Criteria

The most restrictive noise level limits at noise-sensitive receivers in the Project area and vicinity during daytime and nighttime hours are Fresno County's exterior noise standards. For noise-sensitive receivers located in the Project area, the daytime noise standard of 50 dBA L_{50} and nighttime standard of 45 dBA L_{50} are the applicable noise standards at nearby noise-sensitive receivers. Madera County and city of Mendota use L_{eq} values.

[2] Although the Notice of Intent/Notice of Preparation was filed in 2009, traffic counts from 2011 were used to represent existing conditions. There was no significant increase in traffic volume between these 2 years.

Because the usage factor that is applied to construction activities throughout the noise analysis, the L_{50} and L_{eq} noise metrics are considered to be equivalent. Fresno County's Noise Ordinance, Madera County's Noise Ordinance, and the city of Mendota's Noise Element have different construction noise exempt times. All three jurisdictions' construction noise exempt times have been taken into consideration in order to generate one set of construction noise exempt times so that no individual jurisdiction's regulations regarding construction noise exempt times are violated. Construction noise for the Project would be exempt from local noise standards in all relevant jurisdictions on weekdays from 7:00 a.m. to 7:00 p.m. and on Saturday from 9:00 a.m. to 5:00 p.m. Construction noise is prohibited on Federal holidays. Construction activities conducted on Sundays would have to meet the daytime and nighttime noise standards.

California Environmental Quality Act (CEQA) guidelines and thresholds require that significant environmental impacts be identified and that these impacts be eliminated or mitigated to the extent feasible. According to CEQA, resource impact assessment involves the comparison of existing or "baseline" conditions with Project conditions. Section XI of Appendix G of the State CEQA Guidelines (Cal. Code Regs., tit. 14, Appendix G) sets forth characteristics that may signal a potentially significant impact. The following thresholds for determining the significance of impacts related to noise are contained in the Environmental Checklist Form in Appendix G of the State CEQA Guidelines, as amended. Under National Environmental Policy Act (NEPA) Council on Environmental Quality Regulations, effects must be evaluated in terms of their context and intensity. These factors have been considered when applying the CEQA Guidelines. The State CEQA Guidelines ask whether a proposed project would result in:

- Exposure of persons to, or generation of, noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies.
- Exposure of persons to, or generation of, excessive ground-borne vibration or ground-borne noise levels.
- A substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project.
- A substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project.
- Exposure of people residing or working in the project area to excessive noise levels for a project located within an airport land use plan, or where such a plan has not been adopted, within 2 miles of a public airport or public use airport, or for a project within the vicinity of a private airstrip.

The State CEQA Guidelines do not provide a definition for "substantial increase" in noise and they do not provide a threshold of significance for potential noise or vibration impacts. Therefore, the effects from noise and vibration would be considered when above the following thresholds. These thresholds apply to both the proposed project's impacts for all of the project alternatives and cumulative impacts.

Changes in a noise level of less than 3 dBA are not typically noticed by the human ear. Some individuals who are extremely sensitive to changes in noise may notice changes from 3 to 5 dBA. Based on this information, the following thresholds have been used to evaluate effects for both long-term, permanent increases and temporary or periodic increases in ambient noise levels:

- An increase of 3 dBA or greater in noise level that occurs due to Project-related activities would be significant if the resulting noise levels would cause local noise standards to be exceeded, or result in a 3 dBA increase in noise to a land use experiencing levels above local noise compatibility thresholds of "normally acceptable." A noise level increase of less than 3 dBA under either of the previously described scenarios is not considered to be significant.
- An increase of 5 dBA or less in noise level that occurs from Project-related activities would not be considered significant if the resulting noise levels remain below the "acceptable" thresholds established by local standards.
- Increases in noise greater than 5 dBA would be considered significant if the resulting noise levels are above local standards.
- Otherwise the effects of increasing noise levels greater than 5 dBA due to Project-related activities would be evaluated by comparison to other applicable guidelines.

The effects of temporary, short-, and long-term ground-borne vibration due to Project-related activities have been evaluated qualitatively where Project implementation would generate or result in the exposure of sensitive receptors to vibration levels that exceed FTA's vibration standard of 72 VdB. The ground-borne vibration and ground-borne noise impact criteria for general assessments are described in Table 8-1 of the FTA Manual (2006). This table is reproduced below as Table 17-12.

Table 17-12.
Ground-Borne Vibration and Ground-Borne Noise Impact Criteria for General Assessment

Land Use Category	Ground-Borne Vibration Impact Levels (VdB)			Ground-Borne Noise Impact Levels (dB)		
	Frequent Events	Occasional Events	Infrequent Events	Frequent Events	Occasional Events	Infrequent Events
Category 1: Buildings where vibrations would interfere with interior operations	65	65	65	NA	NA	NA
Category 2: Residences and buildings where people normally sleep	72	75	80	35	38	43
Category 3: Institutional land uses with primary daytime use	75	78	83	40	43	48

Source: FTA 2006

Notes:

Frequent events are defined as more than 70 vibration events of the same source per day.

Occasional events are defined as 30 to 70 vibration events of the same source per day.

Infrequent events are defined as fewer than 30 vibration events of the same kind per day.

17.3.3 Impacts and Mitigation Measures

This section provides an evaluation of direct and indirect effects of the Project alternatives on noise sensitive receivers. It includes analyses of potential effects relative to the No-Action Alternative in accordance with NEPA and potential impacts compared to existing conditions to meet CEQA requirements. The analysis is organized by Project alternative with specific impact topics numbered sequentially under each alternative. With respect to noise and vibration, the environmental impact issues and concerns are:

1. Exposure of Sensitive Receptors to Temporary Construction Noise.
2. Exposure of Sensitive Receptors to Temporary Construction Vibration.
3. Increased Off-site Vehicular Traffic Noise due to Construction Related Trips.
4. Noise Effects due to Operation and Maintenance Activities.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. However, other proposed actions under the San Joaquin River Restoration Program (SJRRP) would be implemented, including habitat restoration in other reaches, augmentation of river

flows, and reintroduction of salmon. Without the Project in Reach 2B, however, these Program-level activities would not achieve Settlement goals. The analysis is a comparison to existing conditions, and no mitigation is required for the No-Action Alternative.

Impact NOI-1 (No-Action Alternative): *Exposure of Sensitive Receptors to Temporary Construction Noise.* Under the No-Action Alterative, the Project would not be implemented and there would be no short-term construction activities in the Project area. In addition, there would be no construction equipment or construction related activities in the Project area. As a result, there would be **no impact** on any nearby existing noise sensitive receptors.

Impact NOI-2 (No-Action Alternative): *Exposure of Sensitive Receptors to Temporary Construction Vibration.* Under the No-Action Alterative, the Project would not be implemented and there would be no short-term construction activities in the Project area. In addition, there would be no construction equipment or construction related activities in the Project area. As a result, there would be **no impact** on any nearby existing vibration sensitive receptors.

Impact NOI-3 (No-Action Alternative): *Increased Off-Site Vehicular Traffic Noise due to Construction Related Trips.* Under the No-Action Alternative, the Project would not be implemented and there would be no short-term construction activities in the Project area. In addition, there would be no construction-related vehicular trips going to and from the Project area. Table 17-13, shown below, shows the change in CNEL between existing conditions and the No-Action Alternative as a result of traffic conditions would be less than 1 dBA CNEL. As a result, there would be a **less than significant** impact.

Table 17-13.
Change in Traffic Noise between Existing Conditions and No-Action Alternative

Road Segments	Speed Limit (mph)	Existing (2009)		No-Action (2035)		Change in CNEL (dBA)
		ADT	CNEL (dBA) at 50 feet (feet)	ADT	CNEL (dBA) at 50 feet (feet)	
Bass Avenue east of SR-33	25	510	50	632	50	1
San Mateo Road north of SR-180	25	547	50	678	51	1
SR-33 south of SR-180/33 Junction	55	11,800	73	14632	74	1
SR-33 north of SR-180/33 Junction	55	5,600	71	6944	72	1
SR-180 west of San Mateo Avenue	55	8,200	70	10168	71	1
SR-180 east of San Mateo Avenue	55	8,200	70	10168	71	1

ADT = average daily traffic
CNEL = Community Noise Equivalent Level
dBA = A-weighted decibel(s)
mph = miles per hour

Impact NOI-4 (No-Action Alternative): ***Noise Effects due to Operations and Maintenance Activities.*** Under the No-Action Alterative, the Project would not be implemented and there would be no operation and maintenance activities in the Project area. In addition, there would be no operation and maintenance related vehicular trips going to and from the Project area. As a result, there would be a **no impact** due to increases in off-site vehicular traffic.

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

Alternative A would entail construction of new Project facilities, including a new levee system to establish a bypass channel to the north/east of the existing river channel. Other key features include construction of a fish barrier below Mendota Dam, the Mendota Pool Dike (separating the San Joaquin River and Mendota Pool), and the South Canal and South Canal bifurcation structure further upstream. No construction activities are proposed at or near Mendota Dam, which falls outside the Project boundary under Alternative A. Construction activity is expected to occur intermittently over an approximate 132-month timeframe.

Impact NOI-1 (Alternative A): ***Exposure of Sensitive Receptors to Temporary Construction Noise.*** Compared to the No-Action Alternative, construction activities associated with Alternative A have the potential to generate a short-term increase in noise on the surrounding environs. The loudest construction activities that would be conducted during Alternative A would be the construction of the Compact Bypass grade control structures, South Canal bifurcation structure, fish passage facilities, fish screens, and a fish barrier where the use of pile driving equipment is expected or possible. Appendix 17-C lists the distances to the daytime 50 and nighttime 45 dBA L_{eq} noise contours for all groups of construction activities that originate from the Project construction activities that would be conducted for Alternative A. Although the majority of the construction activities are anticipated to be conducted during construction noise exempt hours (weekdays 7:00 a.m. to 7:00 p.m., Saturday 9:00 a.m. to 5:00 p.m.), nighttime construction may occur. Construction activities associated with Alternative A have the potential to generate temporary adverse effects at noise-sensitive receivers if construction activities are conducted within the daytime 50 dBA L_{eq} or nighttime 45 dBA L_{eq} noise contours during nights and weekends (outside of the construction noise exempt hours).

When comparing Alternative A to existing conditions, impacts to noise would be similar to those discussed in the preceding paragraph (i.e., the comparison of Alternative A to the No-Action Alternative). Depending on the construction activity, distances to the daytime 50 dBA L_{eq} noise contours range from 2,500 to 21,700 feet and the nighttime 45 dBA L_{eq} noise contours range from 4,400 to 38,600 feet. Although the majority of the construction activities are anticipated to be conducted during the daytime and during construction noise exempt hours, nighttime construction may occur. Construction activities associated with Alternative A would generate a **potentially significant** impact.

Mitigation Measure NOI-1 (Alternative A): ***Reduce Temporary and Short-Term Noise Levels from Construction-Related Equipment Near Sensitive Receptors***. Construction activities in the Project area will be modified to minimize adverse effects to noise sensitive receptors when construction activities occur within daytime 50 dBA Leq

noise contours or nighttime 45 dBA Leq noise contours outside of construction noise exempt hours. Implementation of the following measures would reduce potential construction noise-related impacts to sensitive receptors to a less-than-significant level. This impact would be **less than significant with mitigation**.

Implementation Action: Project proponents will ensure that the following noise-reduction protocols are implemented, as needed, to reduce temporary and short-term construction-related noise impacts near sensitive receptors.

- Equipment will be used as far away as practical from noise-sensitive uses.
- Construction equipment will be properly maintained per manufacturers' specifications and fitted with the best available noise suppression devices (e.g., mufflers, silencers, wraps). All impact tools will be shrouded or shielded, and all intake and exhaust ports on power equipment will be muffled or shielded.
- Equipment that is quieter than standard equipment will be used, including electrically powered equipment instead of internal combustion equipment where use of such equipment is a readily available substitute that accomplishes Project tasks in the same manner as internal combustion equipment.
- Construction site and haul road speed limits will be established and enforced.
- The use of bells, whistles, alarms, and horns will be restricted to safety and warning purposes only.
- Construction equipment will not idle for extended periods of time when not being used during construction activities.
- When construction activities are conducted within 2,000 feet of noise-sensitive uses, noise measurements will be taken at the nearest noise-sensitive land uses relative to construction activities with a sound-level meter that meets the standards of the American National Standards Institute (ANSI Section S14 1979, Type 1 or Type 2). This would allow that construction noise levels to comply with applicable daytime and nighttime noise standards. When construction noise exceeds applicable daytime and nighttime standards, berms, or stockpiles will be used in an attempt to lower noise levels to within acceptable nontransportation standards. If noise levels are still determined to exceed noise standards, temporary barriers will be erected as close to the construction activities as feasible, breaking the line of sight between the source and receptor where noise levels exceed applicable standards. All acoustical barriers would be constructed with material having a minimum surface weight of 2 pounds per square foot or greater and a demonstrated Sound Transmission Class (STC) rating of 25 or greater, as defined by Test Method E90 of the American Society for Testing and Materials. Placement, orientation, size, and density of acoustical barriers will be specified by a qualified engineer.
- A disturbance coordinator will be designated to post contact information in a conspicuous location near the construction site entrance so that it is clearly

visible to nearby receivers. The coordinator will manage complaints resulting from the construction noise. Reoccurring disturbances will be evaluated by a qualified acoustical consultant to ensure compliance with applicable standards. The disturbance coordinator will contact nearby noise-sensitive receptors, advising them of the construction schedule.

Location: Project areas where construction activities will be conducted within 2,000 feet of noise-sensitive receptors.

Effectiveness Criteria: Effectiveness will be based on public complaints to the SJRRP.

Responsible Agency: Reclamation and the construction contractor.

Monitoring/Reporting Action: Adequacy of the proposed construction practices will be confirmed with Reclamation construction managers and California State Lands Commission (CSLC) monitors.

Timing: Ongoing when construction activities occur outside of construction noise exempt hours.

Impact NOI-2 (Alternative A): ***Exposure of Sensitive Receptors to Temporary Construction Vibration.*** Compared to the No-Action Alternative, vibration levels generated by Project construction activities related to Alternative A have the potential to temporarily increase ground-borne vibration levels near sensitive receptors. Table 17-11 lists vibration source levels for typical construction equipment. Impact pile driving activities would be conducted during the construction of Alternative A and the vibration source level listed for impact pile drivers (104 VdB at a distance of 25 feet) is the reference level that is used for estimating potential annoyance generated by pile driving activities.

It is assumed, as a worst-case scenario for ground-borne vibration levels, that more than 70 vibration events would be conducted per day during pile driving activities. Using this assumption results in a vibration standard of 72 VdB at residences and buildings where people normally sleep. Ground-borne vibration levels generated by pile drivers located less than 300 feet away from sensitive receivers would have an adverse effect on the sensitive receivers. However, all noise-sensitive receivers would be located more than 300 feet away from pile driving activities and effects generated by ground-borne vibration would be minimal.

When comparing Alternative A to existing conditions, impacts to noise would be similar to those discussed in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). All sensitive receivers would be located more than 300 feet away from pile driving activities and there would be a **less than significant** impact.

Impact NOI-3 (Alternative A): ***Increased Off-Site Vehicular Traffic Noise due to Construction Related Trips.*** Compared to the No-Action Alternative, off-site traffic noise levels generated by Project construction worker and truck trips (related to

Alternative A) traveling to and from the Project area have the potential to create a noticeable increase in traffic noise. Tables 17-14 and 17-15 show the change in CNEL (dBA) for the No-Action Alternative (2035) and existing conditions compared to Alternative A, respectively. The largest increase in vehicular traffic noise would be along San Mateo Avenue where three noise-sensitive receivers (LT-2, R-7 and R-6) would experience a traffic noise increase of up to 15 dBA CNEL, as compared to the No-Action Alternative. The increase in traffic noise is the result of construction-related truck traffic traveling up and down San Mateo Avenue delivering materials to the designated stockpile staging areas. This increase in noise would have a temporary adverse effect on the homes along San Mateo Avenue.

Table 17-14.
Change in Traffic Noise between No-Action Alternative and Alternative A

Road Segments	Speed Limit (mph)	No-Action (2035)		Alternative A (2035)		Change in CNEL (dBA)
		ADT	CNEL (dBA) at 50 feet (feet)	ADT	CNEL (dBA) at 50 feet (feet)	
Bass Avenue east of SR-33	25	632	50	832	51	0
San Mateo Road north of SR-180	25	678	51	2,690	66	15
SR-33 south of SR-180/33 Junction	55	14,632	74	15,098	74	1
SR-33 north of SR-180/33 Junction	55	6,944	72	7,225	73	0
SR-180 west of San Mateo Avenue	55	10,168	71	10,853	72	2
SR-180 east of San Mateo Avenue	55	10,168	71	10,950	73	2

ADT = average daily traffic
CNEL = Community Noise Equivalent Level
dBA = A-weighted decibel(s)
mph = miles per hour

Table 17-15.
Change in Traffic Noise between Existing Condition and Alternative A

Road Segments	Speed Limit (mph)	Existing (2009)		Alternative A (2009)		Change in CNEL (dBA)
		ADT	CNEL (dBA) at 50 feet (feet)	ADT	CNEL (dBA) at 50 feet (feet)	
Bass Avenue east of SR-33	25	510	50	710	50	1
San Mateo Road north of SR-180	25	547	50	2,559	66	16
SR-33 south of SR-180/33 Junction	55	11,800	73	12,266	73	1
SR-33 north of SR-180/33 Junction	55	5,600	71	5,881	72	1
SR-180 west of San Mateo Avenue	55	8,200	70	8,885	72	2
SR-180 east of San Mateo Avenue	55	8,200	70	8,982	72	2

ADT = average daily traffic
CNEL = Community Noise Equivalent Level
dBA = A-weighted decibel(s)
mph = miles per hour

When comparing Alternative A to existing conditions, impacts to construction-related traffic noise would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative A to the No-Action Alternative). The noise-sensitive receivers located along San Mateo Avenue would experience a noise increase of up to 16 dBA CNEL from construction-related truck traffic (which is greater than the 5 dBA CNEL significance criteria) and this increased traffic would not necessarily occur during construction exempt times. Therefore, impacts would be **potentially significant**.

Mitigation Measure NOI-3 (Alternative A): *Reduce Temporary Noise Levels from Construction-Related Traffic Increases Near Sensitive Receptors*. Construction-related activities will be modified to reduce temporary and short-term traffic noise at sensitive receptors along San Mateo Avenue when construction-related traffic noise is generated outside of construction noise exempt hours. Implementation of the following measures would reduce potential construction-related traffic noise impacts along San Mateo Avenue to a less-than-significant level. This impact would be **less than significant with mitigation**.

Implementation Action: Project proponents will ensure that the following noise-reduction protocols are implemented on haul routes near sensitive receptors along San Mateo Avenue to reduce temporary and short-term construction-related traffic noise generated outside of construction noise exempt hours.

- Equip all heavy trucks with noise-control devices (e.g., mufflers) in accordance with manufacturers' specifications.
- Inspect all heavy trucks periodically to ensure proper maintenance and presence of noise-control devices (e.g., lubrication, non-leaking mufflers, and shrouding).
- Establish and implement measures to reduce haul truck operation speeds, limit the amount of borrow site material to be hauled daily, and limit the hours of operation for haul trucks.
- Install temporary noise barriers adjacent to sensitive receptor locations, as needed.

Location: Haul routes near sensitive receptors along San Mateo Avenue.

Effectiveness Criteria: Effectiveness will be based on public complaints to the SJRRP.

Responsible Agency: Reclamation and the construction contractor.

Monitoring/Reporting Action: Adequacy of the proposed construction practices will be confirmed with Reclamation construction managers and CSLC monitors.

Timing: Ongoing when construction activities occur outside of construction noise exempt hours.

Impact NOI-4 (Alternative A): ***Noise Effects due to Operation and Maintenance Activities.*** Compared to the No-Action Alternative (which would not require additional operation and maintenance activities), operation and maintenance activities associated with Alternative A would not generate a noticeable increase in noise on the surrounding environs. The primary noise source due to operation of the Project would be generated by the increase in traffic caused by the workers going to and from the Project site for operational and maintenance activities. Tables 17-16 and 17-17 illustrate the increases in ADT volumes going into the Project area during both operational and maintenance activities, respectively. The highest possible increase in traffic would occur during maintenance activities at the South Canal control structures and San Mateo Avenue, and would result in an increase of eight trips to the traffic volume. When compared to the traffic along the access routes leading into the Project area, an addition of eight trips would not result in a noticeable change in traffic noise. As a result, there would be a minimal effect on all nearby noise-sensitive receivers.

When comparing Alternative A to existing conditions, impacts to noise would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative A to the No-Action Alternative). The increase in traffic due to operation and maintenance activities would result in a **less than significant** impact.

Table 17-16.
Alternative A Operational Activity ADTs

Operational Activity	Assumptions	ADT
South Canal - river side control structure		
Inspection of gates, seals	periodically throughout flows into the bypass channel	2
Make adjustments	when needed	2
Assessment after flows	when flows to the bypass cease	2
Inspection of ladder	periodically throughout flows into the bypass channel, 1 staff for 1 hour during inspection of gates	2
South Canal - canal side control structure		
Inspection of gates, seals	periodically throughout flows into the bypass channel	2
Make adjustments	when needed	2
Assessment after flows	when flows to the bypass cease	2
San Mateo Avenue		
Road closure	1 worker for 4 hours, 2x per year	2
Fish Screen		
Inspections, flow verification, clear debris	1 Water Tech, 120 days.	2
Velocity measurements	2 DWR Divers, 2x per year, 8 hours per screen, 4 screens	4
Fish Barrier		
Inspection, flow verification, clear debris	1 Water Tech, 120 days.	2
Install/Remove barrier screens	2 Water Techs, one week to install the barrier screens and one week for removal	4

ADT = average daily traffic

Table 17-17.
Alternative A Maintenance Activity ADTs

Maintenance Activity	Assumptions	ADT
South Canal - river side control structure		
Sediment removal from channel	2 workers for one day, 2x per year	4
Lube gates	2 workers for one day, 1x per year	4
Fish Ladder Cleaning	periodically throughout flows into the river, 2 staff	4
Fish attraction pipeline Cleaning	periodically throughout flows into the river, 2 staff	4
South Canal - canal side control structure		
Sediment removal from channel	4 workers for one week, 1x per year	8
Lube gates	2 workers for one day, 1x per year	4
Channel Survey	Survey crew of 4, 2 engineers and 2 techs for one week 1x per year	8
Channel reshaping	4 workers for one week, 1x per year	8
San Mateo Avenue		
Cleaning out culverts	4 workers, 2 days, 1x per year	8

ADT = average daily traffic

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Key features of Alternative B include construction of a new levee system to establish a bypass channel northeast of the existing river channel, Compact Bypass Control Structure, Mendota Pool Control Structure, and re-route of Drive 10 ½. No construction activities are proposed at or near Mendota Dam, which falls outside the project boundary under Alternative B. Construction activity is expected to occur intermittently over an approximate 157-month timeframe.

Impact NOI-1 (Alternative B): ***Exposure of Sensitive Receptors to Temporary Construction Noise.*** Compared to the No-Action Alternative, construction activities associated with Alternative B have the potential to generate a short-term increase in noise on the surrounding environs. The loudest construction activities that would be conducted during Alternative B would be the construction of the Compact Bypass grade control structures, Compact Bypass Bifurcation Structure, fish passage facilities, fish screens, and a fish barrier where the use of pile driving equipment is expected or possible. Appendix 17-C lists the distances to the daytime 50 and nighttime 45 dBA L_{eq} noise

contours for all groups of construction activities that would be conducted for Alternative B. Although the majority of the construction activities are anticipated to be conducted during construction noise exempt hours (weekdays 7:00 a.m. to 7:00 p.m., Saturday 9:00 a.m. to 5:00 p.m.), nighttime construction may occur. Construction activities associated with Alternative B have the potential to generate temporary adverse effects at noise-sensitive receivers as compared to the No-Action Alternative if construction activities are conducted within the daytime 50 dBA L_{eq} or nighttime 45 dBA L_{eq} noise contours during nights and weekends (outside of the construction noise exempt hours).

When comparing Alternative B to existing conditions, impacts to noise would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative B to the No-Action Alternative). Depending on the construction activity, distances to the daytime 50 dBA L_{eq} noise contours range from 2,200 to 21,700 feet and the nighttime 45 dBA L_{eq} noise contours range from 4,000 to 38,600 feet. Although the majority of the construction activities are anticipated to be conducted during the daytime and during construction noise exempt hours, nighttime construction may occur. Construction activities associated with Alternative B would generate a **potentially significant** impact.

Mitigation Measure NOI-1 (Alternative B): ***Reduce Temporary and Short-Term Noise Levels from Construction-Related Equipment Near Sensitive Receptors.*** Refer to Mitigation Measure NOI-1 (Alternative A). The same measure would be used here. Impacts would be **less than significant** with implementation of the mitigation measure.

Impact NOI-2 (Alternative B): ***Exposure of Sensitive Receptors to Temporary Construction Vibration.*** Refer to Impact NOI-2 (Alternative A) for more information. Pile driving activities are anticipated to be conducted more than 300 feet away from each identified sensitive receiver, and there would be a **less than significant** impact.

Impact NOI-3 (Alternative B): ***Increased Off-Site Vehicular Traffic Noise due to Construction Related Trips.*** Compared to the No-Action Alternative, off-site traffic noise levels generated by Project construction worker and truck trips (related to Alternative B) traveling to and from the Project area have the potential to create a noticeable increase in traffic noise. Tables 17-18 and 17-19, shown below, show the change in CNEL (dBA) for the No-Action Alternative and existing conditions compared to Alternative B, respectively. The largest increase in vehicular traffic noise, as compared to the No-Action Alternative, would be along San Mateo Avenue where three noise sensitive receivers (LT-2, R-7 and R-6) would experience a traffic noise increase of up to 15 dBA CNEL. This increase in traffic noise is a result of construction related truck traffic traveling up and down San Mateo Avenue delivering construction related materials to the designated stockpile staging areas. This increase in noise would have a temporary adverse effect on the homes along San Mateo Avenue.

When comparing Alternative B to existing conditions, impacts to noise would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative B to the No-Action Alternative). The noise sensitive receivers located along San Mateo Avenue would experience a noise increase of up to 16 dBA CNEL from construction related truck

traffic and this increased traffic would not necessarily occur during construction exempt times. Therefore, impacts would be **potentially significant**.

Table 17-18.
Change in Traffic Noise between No-Action Alternative and Alternative B

Road Segments	Speed Limit (mph)	No-Action (2035)		Alternative B (2035)		Change in CNEL (dBA)
		ADT	CNEL (dBA) at 50 feet (feet)	ADT	CNEL (dBA) at 50 feet (feet)	
Bass Avenue east of SR-33	25	632	50	832	51	0

SR-33 north of SR-180/33 Junction	55	6,944	72	7,226	73	0
SR-180 west of San Mateo Avenue	55	10,168	71	10,794	72	2
SR-180 east of San Mateo Avenue	55	10,168	71	10,922	73	2

ADT = average daily traffic
CNEL = Community Noise Equivalent Level
dBA = A-weighted decibel(s)
mph = miles per hour

Table 17-19.
Change in Traffic Noise between Existing (2009) Condition and Alternative B (2009) (CNEL dBA)

Road Segments	Speed Limit (mph)	Existing (2009)		Alternative B (2009)		Change in CNEL (dBA)
		ADT	CNEL (dBA) at 50 feet (feet)	ADT	CNEL (dBA) at 50 feet (feet)	
Bass Avenue east of SR-33	25	510	50	710	50	1
San Mateo Road north of SR-180	25	547	50	2,443	66	16
SR-33 south of SR-180/33 Junction	55	11,800	73	12,236	73	1
SR-33 north of SR-180/33 Junction	55	5,600	71	5,882	72	1
SR-180 west of San Mateo Avenue	55	8,200	70	8,826	72	2
SR-180 east of San Mateo Avenue	55	8,200	70	8,954	72	2

ADT = average daily traffic
CNEL = Community Noise Equivalent Level
dBA = A-weighted decibel(s)
mph = miles per hour

Mitigation Measure NOI-3 (Alternative B): *Reduce Temporary Noise Levels from Construction-Related Traffic Increases Near Sensitive Receptors*. Refer to Mitigation Measure NOI-3 (Alternative A). The same measure would be used here. Impacts would be **less than significant** with implementation of the mitigation measure.

Impact NOI-4 (Alternative B): ***Noise Effects due to Operation and Maintenance Activities.*** Compared to the No-Action Alternative (which would not require additional operation and maintenance activities), operation and maintenance activities associated with Alternative B would not generate a noticeable increase in noise on the surrounding environs. The primary noise source due to operation of the Project would be generated by the increase in traffic caused by the workers going to and from the Project site for operational and maintenance activities. Tables 17-20 and 17-21, shown below, illustrate the increases in ADT volumes going into the Project area during both operational and maintenance activities, respectively. The highest possible increase in traffic would occur during maintenance activities at the Compact Bypass Bifurcation Structure and San Mateo Avenue, which would result in an increase of eight trips to the traffic volume. When compared to the ambient traffic along the access routes leading into the Project area, an addition of eight trips would not result in a noticeable change in traffic noise. As a result, there would be a minimum effect on all nearby noise sensitive receivers.

When comparing Alternative B to existing conditions, impacts to noise would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative B to the No-Action Alternative). The increase in traffic due to operation and maintenance activities would result in a **less than significant** impact.

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Key features of Alternative C for noise and vibration include construction of new fish passage facilities at Mendota Dam, grade control structures downstream of Mendota Dam, a new Fresno Slough Dam, and Main Canal and Helm Ditch relocations.

Construction activity is expected to occur intermittently over an approximate 133-month timeframe.

Impact NOI-1 (Alternative C): ***Exposure of Sensitive Receptors to Temporary Construction Noise.*** Compared to the No-Action Alternative, construction activities associated with Alternative C have the potential to generate a short-term increase in noise on the surrounding environs. The loudest construction activities that would be conducted during Alternative C would be the construction of the Fresno Slough Dam, Short Canal control structure, fish passage facilities and fish screens, modifications of Mendota Dam including installation of downstream grade control structures where the use of pile driving equipment is expected or possible. Appendix 17-C lists the distances to the daytime 50 and nighttime 45 dBA L_{eq} noise contours for all groups of construction activities that would be conducted for Alternative C. Although the majority of the construction activities are anticipated to be conducted during construction noise exempt hours (weekdays 7:00 a.m. to 7:00 p.m., Saturday 9:00 a.m. to 5:00 p.m.), nighttime construction may occur. Construction activities associated with Alternative C, as compared to the No-Action Alternative, have the potential to generate temporary adverse effects at noise-sensitive receivers if construction activities are conducted within the daytime 50 L_{eq} dBA or nighttime 45 dBA L_{eq} noise contours during nights and weekends (outside of the construction noise exempt hours).

When comparing Alternative C to existing conditions, impacts to noise would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative C to the No-Action Alternative). Depending on the construction activity, distances to the daytime 50 dBA L_{eq} noise contours range from 2,900 to 21,700 feet and the nighttime 45 dBA L_{eq} noise contours range from 5,200 to 38,600 feet. Although the majority of the construction activities are anticipated to be conducted during the daytime and during construction noise exempt hours, nighttime construction may occur. Construction activities associated with Alternative C would generate a **potentially significant** impact.

Mitigation Measure NOI-1 (Alternative C): ***Reduce Temporary and Short-Term Noise Levels from Construction-Related Equipment Near Sensitive Receptors.*** Refer to Mitigation Measure NOI-1 (Alternative A). The same measure would be used here. Impacts would be **less than significant** with implementation of the mitigation measure.

Impact NOI-2 (Alternative C): ***Exposure of Sensitive Receptors to Temporary Construction Vibration.*** Compared to the No-Action Alternative, vibration levels generated by Project construction activities related to Alternative C have the potential to temporarily increase ground-borne vibration levels near sensitive receptors. Ground-borne vibration levels generated by pile drivers located less than 300 feet away from sensitive receivers would have an adverse effect on the sensitive receivers. (Refer to Impact NOI-2 (Alternative A) for more information.) One residential structure would be located approximately 260 feet away from pile driving activities under Alternative C and therefore effects generated by ground-borne vibration could be noticeable.

When comparing Alternative C to existing conditions, impacts to noise would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative C to the

No-Action Alternative). Pile driving activities are anticipated to be conducted within 300 feet of an identified sensitive receiver, and therefore impacts would be **potentially significant**.

Mitigation Measure NOI-2 (Alternative C): *Minimize Vibration Related Effects.* Construction activities in the Project area will be modified to minimize adverse effects to the public or the environment, including implementing control measures prior to and during pile driving activities. Implementation of the following measures would reduce potential vibration-related effects to a less-than-significant level. This impact would be **less than significant with mitigation**.

Implementation Action: The contractors will implement the following actions to minimize potential vibration-related effects:

- Notify nearby homeowners of pile driving activities when pile driving would be conducted within 300 feet or less of residential structures.
- Conduct pile driving activities during daytime hours only (between 7:00 a.m. to 7:00 p.m.).
- Utilize drill-and-casing methods or a vibratory pile driver when conducting pile driving activities within 300 feet or less of residential structures.

Location: Project areas where pile driving construction activities will be conducted within 300 feet or less of sensitive receptors.

Effectiveness Criteria: Effectiveness will be based on public complaints to the SJRRP.

Responsible Agency: Reclamation and the construction contractor.

Monitoring/Reporting Action: Adequacy of the proposed construction practices will be confirmed with Reclamation construction managers and CSLC monitors.

Timing: Ongoing during pile driving construction activities within 300 feet or less of residential structures.

Impact NOI-3 (Alternative C): *Increased Off-Site Vehicular Traffic Noise due to Construction Related Trips.* Compared to the No-Action Alternative, off-site traffic noise levels generated by Project construction worker and truck trips (related to Alternative C) traveling to and from the Project area have the potential to create a noticeable increase in traffic noise. Tables 17-22 and 17-23, shown below, show the change in CNEL (dBA) for the No-Action Alternative and existing conditions compared to Alternative C, respectively. The largest increase in vehicular traffic noise, compared to the No-Action Alternative, would be along San Mateo Avenue where three noise sensitive receivers (LT-2, R-7 and R-6) would experience a traffic noise increase of up to 14 dBA CNEL. This increase in traffic noise is a result of construction related truck traffic traveling up and down San Mateo Avenue delivering construction related materials

to the designated stockpile staging areas. This increase in noise would have a temporary adverse effect on the homes along San Mateo Avenue.

When comparing Alternative C to existing conditions, impacts to construction-related traffic noise would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative C to the No-Action Alternative). The noise sensitive receivers located along San Mateo Avenue would experience a noise increase of up to 15 dBA CNEL from construction related truck traffic and this increased traffic would not necessarily occur during construction exempt times. Therefore, impacts would be **potentially significant**.

ADT = average daily traffic

When comparing Alternative C to existing conditions, impacts to noise would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative C to the No-Action Alternative). The increase in traffic due to operation and maintenance activities would result in a **less than significant** impact.

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Key features of Alternative D for noise and vibration include construction of new fish passage facilities at Mendota Dam, grade control structures downstream of Mendota Dam, Fresno Slough Dam, Main Canal and Helm Ditch relocations, and the North Canal. Construction activity is expected to occur intermittently over an approximate 158-month timeframe.

Impact NOI-1 (Alternative D): ***Exposure of Sensitive Receptors to Temporary Construction Noise.*** Compared to the No-Action Alternative, construction activities associated with Alternative D have the potential to generate a short-term increase in noise on the surrounding environs. The loudest construction activities that would be conducted during Alternative D would be the construction of Fresno Slough Dam, North Canal bifurcation structure, fish passage facilities, fish screens, and a fish barrier where the use of pile driving equipment is expected or possible. Appendix 17-C lists the distances to the daytime 50 and nighttime 45 dBA L_{eq} noise contours for all groups of construction activities that would be conducted for Alternative D. Although the majority of the construction activities are anticipated to be conducted during construction noise exempt hours (weekdays 7:00 a.m. to 7:00 p.m., Saturday 9:00 a.m. to 5:00 p.m.), nighttime construction may occur. Construction activities associated with Alternative D, in comparison to the No-Action Alternative, have the potential to generate temporary adverse effects at noise-sensitive receivers if construction activities are conducted within the daytime 50 dBA L_{eq} or nighttime 45 dBA L_{eq} noise contours during nights and weekends (outside of the construction noise exempt hours).

When comparing Alternative D to existing conditions, impacts to noise would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative D to the No-Action Alternative). Depending on the construction activity, distances to the daytime 50 dBA L_{eq} noise contours range from 2,200 to 21,700 feet and the nighttime 45 dBA L_{eq} noise contours range from 4,000 to 38,600 feet. Although the majority of the construction activities are anticipated to be conducted during the daytime and during construction noise exempt hours, nighttime construction may occur. Construction activities associated with Alternative D would generate a **potentially significant** impact.

Mitigation Measure NOI-1 (Alternative D): ***Reduce Temporary and Short-Term Noise Levels from Construction-Related Equipment Near Sensitive Receptors.*** Refer to Mitigation Measure NOI-1 (Alternative A). The same measure would be used here. Impacts would be **less than significant** with implementation of the mitigation measure.

Impact NOI-2 (Alternative D): ***Exposure of Sensitive Receptors to Temporary Construction Vibration.*** Refer to Impact NOI-2 (Alternative C) for more information. Pile driving activities are anticipated to be conducted within 300 feet away from an identified sensitive receiver, and therefore impacts would be **potentially significant**.

Mitigation Measure NOI-2 (Alternative C): ***Minimize Vibration Related Effects.*** Refer to Mitigation Measure NOI-2 (Alternative C). The same measure would be used here. Impacts would be **less than significant** with implementation of the mitigation measure.

Impact NOI-3 (Alternative D): ***Increased Off-Site Vehicular Traffic Noise due to Construction Related Trips.*** Compared to the No-Action Alternative, off-site traffic noise levels generated by Project construction worker and truck trips (related to Alternative D) traveling to and from the Project area have the potential to create a noticeable increase in traffic noise. Tables 17-26 and 17-27, shown below, show the change in CNEL (dBA) for the No-Action Alternative and existing conditions compared to Alternative D, respectively. The largest increase in vehicular traffic noise, as compared to the No-Action Alternative, would be along San Mateo Avenue where three noise sensitive receivers (LT-2, R-7 and R-6) would experience a traffic noise increase of up to 14 dBA CNEL. This increase in traffic noise is a result of construction related truck traffic traveling up and down San Mateo Avenue delivering construction related materials to the designated stockpile staging areas. This increase in noise would have a temporary adverse effect on the homes along San Mateo Avenue.

SR-33 north of SR-180/33 Junction	55	5,600	71	5,808	72	0
SR-180 west of San Mateo Avenue	55	8,200	70	8,693	71	1
SR-180 east of San Mateo Avenue	55	8,200	70	8,781	72	2

ADT = average daily traffic
CNEL = Community Noise Equivalent Level
dBA = A-weighted decibel(s)
mph = miles per hour

When comparing Alternative D to existing conditions, impacts to construction-related traffic noise would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative D to the No-Action Alternative). The noise sensitive receivers located along San Mateo Avenue would experience a noise increase of up to 15 dBA CNEL from construction related truck traffic and this increased traffic would not necessarily occur during construction exempt times. Therefore, impacts would be **potentially significant**.

Mitigation Measure NOI-3 (Alternative D): ***Reduce Temporary Noise Levels from Construction-Related Traffic Increases Near Sensitive Receptors.*** Refer to Mitigation Measure NOI-3 (Alternative A). The same measure would be used here. Impacts would be **less than significant** with implementation of the mitigation measure.

Impact NOI-4 (Alternative D): ***Noise Effects due to Operation and Maintenance Activities.*** Compared to the No-Action Alternative (which would not require additional operation and maintenance activities), operation and maintenance activities associated with Alternative D would not generate a noticeable increase in noise on the surrounding environs. The primary noise source due to operation of the Project would be generated by the increase in traffic caused by the workers going to and from the Project site for operational and maintenance activities. Tables 17-28 and 17-29, shown below, illustrate the increases in ADT volumes going into the Project area during both operational and maintenance activities, respectively. The highest possible increase in traffic would occur during maintenance activities at the North Canal control structures and San Mateo Avenue, which would result in an increase of eight trips to the traffic volume. When compared to the ambient traffic along the access routes leading into the Project area, an addition of eight trips would not result in a noticeable change in traffic noise. As a result, there would be a minimum effect on all nearby noise sensitive receivers.

When comparing Alternative D to existing conditions, impacts to noise would be similar to those described in the preceding paragraph (i.e., the comparison of Alternative D to the No-Action Alternative). The increase in traffic due to operation and maintenance activities would result in a **less than significant** impact.

18.0 Paleontological Resources

Paleontological resources (fossils) are the remains or traces of prehistoric animals and plants. This chapter describes environmental and regulatory settings for scientifically important fossil remains, as well as environmental consequences and mitigation measures, as they pertain to implementation of the Project alternatives in the Project area.

18.1 Environmental Setting

18.1.1 Physiographic Environment

The Project area is located in the San Joaquin Valley. The San Joaquin Valley and the Sacramento Valley comprise the Great Valley, commonly referred to as the Central Valley of California. The Great Valley geomorphic province is located between the Sierra Nevada geomorphic province on the east and the Coast Range geomorphic province on the west, as described in Chapter 10.0, "Geology and Soils."

The Great Valley is composed of thousands of feet of sedimentary deposits that have undergone periods of subsidence and uplift over millions of years. During the Jurassic (approximately 206 million years Before Present [B.P.]) and Cretaceous (approximately 144 million years B.P.) periods of the Mesozoic era, the Great Valley existed in the form of an ancient ocean. By the end of the Mesozoic era, the northern portion of the Great Valley began to fill with sediment as tectonic forces caused uplift of the basin. Geologic evidence suggests that the Sacramento Valley and San Joaquin Valley gradually separated into two separate water bodies as uplift and sedimentation continued. By the time of the Miocene epoch (approximately 24 million years B.P.), sediments deposited in the Sacramento Valley were mostly of terrestrial origin. In contrast, the San Joaquin Valley continued to be inundated with water for another 20 million years, as indicated by marine sediments dated to the late Pliocene epoch (approximately 5 million years B.P.). Most of the surface of the Great Valley is covered with Holocene (i.e., less than 11,000 years B.P.) and Pleistocene (11,000 to 1.5 million years B.P.) alluvium. This alluvium is composed of sediments originating from the Sierra Nevada to the east and the Coast Ranges to the west that were carried by water and deposited on the valley floor. Siltstone, claystone, and sandstone are the primary types of sedimentary deposits.

18.1.2 Geologic Setting

Geologic history and conditions are relevant to the evaluation of paleontological resources because they influence the type of fossils that may be found (i.e., aquatic vs. terrestrial organisms) and the probability that any prehistoric remains would be subject to fossilization rather than normal decay. The depositional history of the San Joaquin Valley during the late Quaternary included several cycles related to fluctuations in regional and global climate that caused alternating periods of deposition followed by periods of subsidence and erosion. Thus, the San Joaquin Valley during the Pleistocene consisted of

stages of wetlands and floodplain creation as tidewaters rose in the valley from the west, areas of erosion when tidewaters receded, and alluvial fan deposition from streams emanating from the adjacent mountain ranges (Bartow 1991).

Regional and local surficial geologic mapping and correlation of the various geologic units in the Project area and vicinity have been provided by Jennings and Strand (1958). Geologic mapping by Jennings and Strand (1958) indicates that the Project components and a surrounding 1-mile buffer zone are located in the following geological rock units:

- **Qsc – Recent River and Major Stream Channel Deposits in the Great Valley (Holocene).** This unit is comprised of sediments along the river channels and major streams including adjacent natural levees.
- **Qf – Recent Alluvial Fan Deposits in the Great Valley (Holocene).** This unit is comprised of granitic sand and silt sediments deposited from streams emerging from highlands surrounding the Great Valley.
- **Qb – Recent Basin Deposits in the Great Valley (Holocene).** This unit is comprised of sediments deposited during flood stages of major streams between natural stream levees and fans.

In addition to these three geological units, the following three geological units likely occur underneath portions of Project area and may be encountered during ground disturbance activities greater than a few feet.

- **Qf – Modesto Formation (Pleistocene).** This unit is comprised of granitic sand and silt river terrace or coalescing alluvial fan deposits emerging from surrounding highlands.
- **Qc – Riverbank Formation (Pleistocene).** This unit is comprised of granitic sand, silt and clay older alluvium and dissected fan deposits.
- **Qp – Turlock Lake Formation (Pliocene-Pleistocene).** This unit is comprised of granitic sand, silt, clay and cobbles alluvium deposits.

18.1.3 Local Paleontological Resources

The following is an inventory and assessment of paleontological resources by rock unit (see Table 18-1). In general, to be considered a fossil, a specimen must be older than recent (approximately 10,000 years old). Because sediments of the Recent River and Major Stream Channel Deposits in the Great Valley (Qsc), the Recent Alluvial Fan Deposits in the Great Valley (Qf), and the Recent Alluvial Fan Deposits in the Great Valley (Qb) are considered Holocene (recent) in age, these sediments are unlikely to contain significant paleontological resources and are considered to have low paleontological sensitivity. These three Holocene (recent) geological units are likely underlain by older Pleistocene age units including the Modesto (Qf) Formation, Riverbank (Qc) Formation, and the Pliocene- Pleistocene Turlock Lake (Qp) Formation. These Pliocene-Pleistocene sediments in the Great Valley are reported to contain significant vertebrate fossils (Stirton 1951, Savage 1951, Jefferson 1991a, Jefferson 1991b and Dundas et al. 1996) and are considered to have high paleontological sensitivity.

Table 18-1.
Rock Unit Description in Reach 2B, San Joaquin Valley, CA

Unit within 1-Mile Buffer Zone of Project Area	Name/Description of Unit	Age	Paleontological Sensitivity
Qsc	Stream Channel Deposits	Holocene	Low
Qf	Fan Deposits	Holocene	Low
Qb	Basin Deposits	Holocene	Low
Qf	Modesto Formation	Pleistocene	High
Qc	Riverbank Formation	Pleistocene	High
Qp	Turlock Lake Formation	Pliocene-Pleistocene	High

A University of California Museum of Paleontology (UCMP) on-line catalogue database search of the Restoration Area, completed in 2009 as part of the Program Environmental Impact Statement/Report (PEIS/R) (San Joaquin River Restoration Program [SJRRP] 2011, page 18-4), located two known fossil localities (V4401 and V6806). In addition, this investigation searched the UCMP on-line catalogue database for Pleistocene vertebrate localities in Fresno and Madera Counties (UCMP 2013) which resulted in four additional locations (V5206, V65100, V81121 and V93128). The paleontological sensitivity of all six areas is high. Details of the localities are provided below and in Table 18-2:

- **V4401:** This locality is in the Modesto Formation and located in the Tranquility area in Fresno County. The area is Pleistocene in age. There are 149 fossil records containing mammals (moles, gophers, mice, wood rats, voles, jack rabbits, coyote, red fox, grey fox, badger, horse, camel, pronghorn antelope, elk, deer, and bison), birds, reptiles (turtles and snakes), and bony fish.
- **V5206**: This locality is located Madera County but the name of the specific Formation was not included in the UCMP database. The area is Pleistocene in age. There is one fossil record containing a mammal (horse).
- **V6806:** This locality is in the Modesto Formation and located in the Merced River 1 area in Merced County. The area is Pleistocene in age. There are four fossil records containing mammals (horse, bison, sloth, and camel).
- **V65100:** This locality is located in the Riverdale area in Fresno County but the name of the specific Formation was included in the UCMP database. The area is Pleistocene in age. There is one fossil record containing a mammal (camel).
- **V81121:** This locality is in the Riverbank Formation and located in the Laguna Seca Ranch area in Fresno County. The area is Pleistocene in age. There is one fossil record containing a mammal (horse).
- **V93128:** is in the Turlock Lake Formation[1] and is located near Fairmead Landfill in Madera County. There are 213 fossil records containing mammals (mammoth,

[1] The UCMP on-line catalogue database lists this locality in the Riverbank Formation but detailed studies by Dundas et al. (1996) place the fossil bearing strata in the Turlock Lake Formation.

ground sloth, giant short-faced bear, saber tooth cat, wolf, deer, camel, horse, antelope, rodents, birds, reptiles, and fish).

Table 18-2.
UCMP Locality Results for the Project Vicinity (Fresno County, Madera County, and the Restoration Area)

Locality Identification Number	Locality Name	Age	Number of Specimens	Paleontological Sensitivity
V4401	Tranquility	Pleistocene	149	High
V5206	Ehrreich	Pleistocene	1	High
V6806	Merced River 1	Pleistocene	4	High
V65100	Riverdale	Pleistocene	1	High
V81121	Laguna Seca Ranch	Pleistocene	1	High
V93128	Fairmead Landfill	Pleistocene	213	High

UCMP = University of California Museum of Paleontology

18.2 Regulatory Setting

Paleontological resources are included among nonrenewable scientific resources by governmental agencies. Protection of such resources is provided by Federal and State legislation and by some local ordinances as described below.

18.2.1 Federal

The National Environmental Policy Act (NEPA) requires that objects of historic or scientific interest be considered in assessing the environmental consequences of any proposed project. Paleontological resources are afforded Federal protection under 40 Code of Federal Regulations 1508.27 as a subset of scientific resources.

Federal regulations protect paleontological resources on Federal or public land. These regulations are listed below:

- **Antiquities Act of 1906 (16 United States Code [USC] 431–433).** This Act authorizes the Federal government to regulate the disturbance of objects of antiquity on Federal lands through the responsible managing agency and to prosecute unauthorized damage or removal.
- **The Federal Land Policy and Management Act of 1976 (Public Law [PL] 94-579; 90 Stat. 2743, USC 1701-1782).** This Act requires that public lands be managed in a manner that protects the quality of their scientific values.
- **The Paleontological Resources Preservation Act (Omnibus Public Land Management Act of 2009, PL 111-011).** This Act regulates who may collect fossils on Federal lands and where such fossils must be curated.

18.2.2 State of California

The primary State environmental law that protects fossils is the California Environmental Quality Act (CEQA; Pub. Resources Code, § 21000 et seq. CEQA requires that public agencies and private interests identify the significance of the impacts of their proposed projects on any object or site of significance to the scientific annals of California (Pub. Resources Code, § 15064.5, subd. (a)(3)), and this requirement applies to paleontological resources. Appendix G of the State CEQA Guidelines contains an Environmental Checklist of questions that a lead agency should normally address if relevant to a project's environmental impacts. One of the questions to be answered in this Environmental Checklist (Cal. Code Regs., § 15063; Appendix G, Section V, Part c) is the following: "Would the project directly or indirectly destroy a unique paleontological resource or site…?"

Other State requirements for the management of paleontological resources are contained in Public Resources Code Chapter 1.7, section 5097.5 (Statutes 1965, Chapter 1136, Page 2792) under the heading of "Archaeological, Paleontological, and Historical Sites." This statute defines any unauthorized disturbance or removal of a fossil site or remains on public land as a misdemeanor and specifies that State agencies may undertake surveys, excavations, or other operations as necessary on publicly owned lands to preserve or record paleontological resources. Public Resources Code section 30244 requires reasonable mitigation of adverse impacts to paleontological resources on State-owned land.

18.2.3 Regional and Local

The Fresno County General Plan (Fresno County 2000) calls for the identification and protection of paleontological resources. These goals and policies are listed below:

- Goal OS-J is "to identify, protect, and enhance Fresno County's important … paleontological … sites and their contributing environment."
- Policy OS-J.1 states that "The County shall require that discretionary development projects, as part of any required CEQA review, identify and protect important … paleontological … sites and their contributing environment from damage, destruction, and abuse to the maximum extent feasible."

The Madera County General Plan (Madera County 1995) calls for preservation incentive programs for owners of important cultural and paleontological resources. These goals and policies are listed below:

- Goal 4.D is "to identify, protect, and enhance Madera County's important … paleontological … sites and their contributing environment."
- Policy 4.D.2 states that "The County shall coordinate with the cities and advisory councils in the county to promote the preservation and maintenance of Madera County's paleontological … resources."
- Policy 4.D.3 states that "The County shall require that discretionary development projects identify and protect from damage, destruction, and abuse, important … paleontological … sites and their contributing environment."

18.3 Environmental Consequences and Mitigation Measures

18.3.1 Impact Assessment Methodology

The Society of Vertebrate Paleontology (SVP) has developed guidelines and professional standards for assessing the impact of projects on paleontological resources and for mitigation of adverse impacts (SVP 1995, SVP 2010).

Paleontological Resource Assessment Criteria

The SVP (1995) Conformable Impact Mitigation Guidelines outline criteria to assess paleontological sensitivity based on the potential of a geologic unit to contain significant paleontological resources. Based on the SVP Guidelines, a vertebrate fossil is considered significant unless otherwise demonstrated, due to the relative rarity of vertebrate fossils. Vertebrate fossils are so uncommon that, in many cases, each recovered specimen will provide additional important information about the morphological variation or the geographic distribution of its species. Additionally, certain invertebrate or botanical fossils are considered significant paleontological resources if they provide new and substantial taxonomic, phylogenetic, ecologic, or stratigraphic data.

An individual fossil specimen may be considered scientifically important if it contains one or more of the following characteristics:

- It is well preserved.
- Can be identified.
- More complete than most specimens for that species.
- Preserves one or more elements not known in most specimens of that species.
- Indicative of a particular time period.
- Has not been recorded from that sedimentary unit.
- Provides information concerning the environment in which it lived.
- Could be the basis for description of a new species or comes from a site that produced the type (definitive) specimen of its species.
- Belongs to a species rarely encountered.

A rock unit is considered "sensitive" to adverse impacts if there is a high probability that grading, excavation, or other earth-moving would jeopardize significant fossil remains. The paleontological importance or sensitivity of each rock unit exposed is the measure most amenable to assessing the significance of paleontological resources because the areal distribution of each rock unit can be delineated on a topographic or geologic map. The paleontological sensitivity of a stratigraphic unit reflects its potential paleontological productivity and sensitivity as well as the scientific significance of the fossils it has produced. This method of paleontological resource assessment is the most appropriate because discrete levels of paleontological importance can be delineated on a topographic or geologic map.

The SVP Guidelines establish three categories of sensitivity for paleontological resources under the standard guidelines for assessment of paleontological resources. The three categories are low, high, and undetermined, as described below.

- Rock units that are not sedimentary in origin (e.g., most igneous and metamorphic rocks) are categorized as low sensitivity paleontological resources. However, sedimentary rock units may also be categorized as low sensitivity if they have been well examined and have not produced paleontological resources. (Monitoring is not usually recommended or needed during excavation in a rock unit with low sensitivity.)
- High sensitivity paleontological resources are categorized as rock units older than Holocene (recent)[2] for which vertebrate or significant invertebrate or suite of plant fossils have been recovered. (In areas of high paleontological sensitivity, full-time monitoring is recommended during ground disturbance activities.)
- Paleontological resources in sedimentary rock units for which little information is available are categorized as undetermined paleontological sensitivity. It is often possible for an experienced paleontologist to determine whether such a rock unit should be assigned a high or low sensitivity after a pedestrian survey is performed and detailed observations of both natural and artificial exposures of the rock unit are made.

Identification of Local Paleontological Resources

A literature review was performed to aid in the evaluation of the paleontological sensitivity of each geologic unit that would be encountered during Project activities. The paleontological literature was reviewed to assess the locations of published fossil localities at the Project area and within a 1-mile buffer zone, and in the geologic units that would be encountered by Project activities. The paleontological literature was also used to assess the types of fossils that might be encountered as well as the scientific importance of the fossils. The review was conducted by a database search at the UCMP on-line catalogue to locate known fossil localities at the Project area and a 1-mile buffer zone. The geological units, the potential for paleontological resources in these geological units, and known fossil in the Project area and vicinity are discussed in Section 18.1.3.

A key aspect used to assess the Project's potential impacts to paleontological resources is the consideration of locations and depths of Project-related ground disturbance in context of the paleontological sensitivity of the affected soils. Paleontological resources can be affected by earth-moving activities; therefore, the impact analysis discusses only those areas where earth-moving activities may occur. Surface sediments in the Project area are unlikely to contain fossils because of the relatively recent formation of the geological units (i.e., sediments deposited less than 10,000 years ago). Therefore, paleontological resources are unlikely to be affected by streambed erosion or by shallow excavations. However, these surface sediments are underlain by older Pleistocene age formations that may contain vertebrate fossils (see Section 18.1.3). Subsurface soil penetrations (e.g., to construct a foundation for a water control structure) potentially could encounter

[2] Holocene or recent age sediments (less than 10,000 years old) are generally considered to be too young to preserve significant fossils.

paleontological resources. Based on the 5 percent design level, subsurface pilings and excavations would extend up to 35 feet in depth.

18.3.2 Significance Criteria

Because most fossils are of now extinct organisms, they are nonrenewable resources. Therefore, fossils are valuable scientific and educational resources that are protected by Federal, State, and local laws and regulations. The primary State environmental law protecting fossils is CEQA, which requires that public agencies and private interests identify the environmental consequences of their proposed projects on any object or site of significance to the scientific annals of California. The thresholds of significance for potential paleontological impacts were based on the Environmental Checklist Form in Appendix G of the State CEQA Guidelines, as amended. Under NEPA Council on Environmental Quality Regulations, effects must be evaluated in terms of their context and intensity. These factors were considered when applying the CEQA Guidelines Appendix G. The Environmental Checklist Form (Cal. Code Regs., tit. 14 § 15063; Appendix G, Section V, c) includes the following: "Would the project directly or indirectly destroy a unique paleontological resource or site…?"

Although neither CEQA nor the State CEQA Guidelines define what is "a unique paleontological resource or site." CEQA section 21083.2, subdivision (g) defines a "unique archaeological resource" as "…an archaeological artifact, object, or site about which it can be clearly demonstrated that, without merely adding to the current body of knowledge, there is a high probability that it meets any of the following criteria:

- Contains information needed to answer important scientific research questions and that there is a demonstrable public interest in that information.
- Has a special and particular quality such as being the oldest of its type or the best available example of its type.
- Is directly associated with a scientifically recognized important prehistoric or historic event or person."

18.3.3 Impacts and Mitigation Measures

This section provides a project-level evaluation of direct and indirect effects of the Project alternatives on paleontological resources. It includes analyses of potential effects relative to No-Action conditions in accordance with NEPA and potential impacts compared to existing conditions to meet CEQA requirements. The analysis is organized by Project alternative. With respect to paleontological resources, the environmental impact issue and concern is:

1. Possible Damage to or Destruction of Unique Paleontological Resources.

Other paleontological-related issues covered in the PEIS/R are not covered here because they are programmatic in nature and/or are not relevant to the Project area.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. However, other proposed actions under the SJRRP would be implemented, including habitat restoration in other reaches, augmentation of river flows, and reintroduction of salmon. Without the Project in Reach 2B, however, these activities would not achieve the Settlement goals. The potential effects of the No-Action Alternative are described below. The analysis is a comparison to existing conditions, and no mitigation is required for No-Action.

Impact PAL-1 (No-Action Alternative): *Possible Damage to or Destruction of Unique Paleontological Resources.* Under the No-Action Alternative, there would be no Project-related construction or ground disturbing activities within the Project area. Therefore, there would be **no impact** on paleontological resources from the Project.

Alternative A (Compact Bypass with Narrow Floodplain and South Canal)

Alternative A would include construction of Project facilities including a Compact Bypass channel, a new levee system encompassing the existing river channel in a narrow floodplain, and the South Canal. Other key features include construction of the Mendota Pool Dike (separating the San Joaquin River and Mendota Pool), a fish barrier below Mendota Dam, and the South Canal bifurcation structure, fish passage facility, and fish screens, modification of the San Mateo Avenue crossing, and the removal of the San Joaquin River control structure at the Chowchilla Bifurcation Structure. Construction activity is expected to occur intermittently over an approximate 132-month timeframe.

Borrow material would primarily be required for the construction of the levees, but it may also be utilized in the construction of other structures for foundation or backfill material. Levees may be constructed entirely of local borrow material, a mix of local and imported borrow material, or just imported borrow material. Borrow locations would be determined after a geotechnical exploration of potential local borrow areas is complete. It is estimated that up to 350 acres of land would be needed for borrow areas. Some of the soils excavated to construct the Compact Bypass and the South Canal might be used for levee construction, and if this is possible, then the size of the borrow areas may be reduced.

Impact PAL-1 (Alternative A): *Possible Damage to or Destruction of Unique Paleontological Resources.* Compared to the No-Action Alternative, Alternative A includes construction and ground-disturbing activities in areas that are underlain by Holocene-age (less than 11,000 years old) alluvium. Construction activities that occur in Holocene alluvium including Recent River and Major Stream Channel Deposits; Recent Alluvial Fan Deposits; and Recent Basin Deposits would not affect paleontological resources.

However, below the Holocene-age alluvium, the Project area is underlain by Pleistocene-age sediments of the Modesto and Riverbank Formations and the Pliocene-Pleistocene-age sediments of the Turlock Lake Formation, which are considered paleontologically sensitive rock units under SVP Guidelines (SVP 1995). Numerous vertebrate fossil

specimens have been recovered or recorded from the Modesto, Riverbank and Turlock Lake Formations throughout the San Joaquin Valley and near the Restoration Area. Consequently, potential exists for uncovering additional, similar fossil remains during construction-related earthmoving activities in the Project area.

When comparing Alternative A to existing conditions, impacts to paleontological resources would be similar to those described in the preceding paragraphs (i.e., the comparison of Alternative A to the No-Action Alternative). Implementation of Alternative A may uncover Pleistocene-age fossil remains during construction-related earthmoving activities in the Project area. This impact is considered **potentially significant**.

Mitigation Measure PAL-1 (Alternative A): *Stop Work if Paleontological Resources Are Encountered During Earthmoving Activities and Implement Recovery Plan.* To minimize potential adverse impacts on unique, scientifically important paleontological resources during earthmoving activities, the following measures would be implemented during construction to reduce possible damage to unique paleontological resources. The contractor will conduct employee training for the construction workers at the site on identification of paleontological resources. If paleontological resources are discovered in local borrow areas, during earthmoving activities, or in the river channel, the construction crew will immediately cease work in the vicinity of the find. A paleontologist approved by Reclamation and/or CSLC staff will evaluate the resource and prepare a recovery plan in accordance with SVP Guidelines (SVP 1995). The recovery plan may include a field survey, construction monitoring, sampling and data recovery procedures, museum storage coordination for any specimen recovered, and a report of findings. Recommendations in the recovery plan will be implemented before construction activities could resume at the site where the paleontological resources were discovered.

Implementing this mitigation measure would reduce potentially significant impacts related to potential damage to unique paleontological resources to a less-than-significant level because if resources were encountered, fossil specimens would be recovered, recorded, and would undergo appropriate curation.[3] This impact would be **less than significant after mitigation**.

> **Implementation Action:** The contractor will conduct employee training for the construction workers at the site on identification of paleontological resources. If paleontological resources are discovered in local borrow areas, during earthmoving activities, or in the river channel, the construction crew would immediately cease work in the vicinity of the find. A paleontologist approved by Reclamation and/or CSLC staff will evaluate the resource and prepare a recovery plan in accordance with SVP Guidelines. Recommendations in the recovery plan will be implemented before construction activities could resume at the site.
>
> **Location:** Construction areas with active excavation.

[3] Curation is management and care of collections according to standard professional practice, which may include inventorying, accessing, labeling, cataloging, identifying, evaluating, documenting, storing, maintaining, periodically inspecting, and/or conserving original collections.

Effectiveness Criteria: Performance tracking of this mitigation measure will be based on the stoppage in work in the vicinity of the find and meeting the recommendations in the recovery plan.

Responsible Agency: U.S. Department of the Interior, Bureau of Reclamation.

Monitoring/Reporting Action: Preparation of a recovery plan in accordance with SVP Guidelines, if paleontological resources are discovered during earthmoving activities and notification of California State Lands Commission (CSLC) monitors if find is on land under the CSLC's jurisdiction.

Timing: Mitigation would be ongoing over the construction timeframe.

Alternative B (Compact Bypass with Consensus-Based Floodplain and Bifurcation Structure), the Preferred Alternative

Alternative B would include construction of Project features including a Compact Bypass channel, a new levee system with a wide, consensus-based floodplain encompassing the river channel, and the Compact Bypass Bifurcation Structure with fish passage facility and fish screen. Other key features include construction of a fish passage facility at the San Joaquin River control structure at the Chowchilla Bifurcation Structure, the re-route of Drive 10 ½ (across the Compact Bypass control structure), and the removal of the San Mateo Avenue crossing. Construction activity is expected to occur intermittently over an approximate 157-month timeframe.

Borrow material would primarily be required for the construction of the levees, but it may also be used in the construction of other structures for foundation or backfill material. Levees may be constructed entirely of local borrow material, a mix of local and imported borrow material, or just imported borrow material. Borrow locations would be determined after a geotechnical exploration of potential local borrow areas is complete; the exploration would determine the suitability of local soils for use as borrow material. It is estimated that up to 350 acres of land would be needed for borrow areas. Some of the soils excavated to construct the Compact Bypass might be used for levee construction, and if this is possible, then the size of the borrow areas may be reduced.

Impact PAL-1 (Alternative B): ***Possible Damage to or Destruction of Unique Paleontological Resources.*** Refer to Impact PAL-1 (Alternative A). Potential impacts of Alternative B would be the same as potential impacts of Alternative A with the following exception. The Compact Bypass design in Alternative B includes fewer grade control structures than the other alternatives, which would initiate channel bed erosion in Reach 2B to remove sediment that has been deposited in the San Joaquin River arm of Mendota Pool. This channel bed erosion is anticipated to be up to 7 to 8 feet deep near the upstream end of the Compact Bypass and gradually decrease to zero erosion approximately 4 miles further upstream (River Mile 210). Since this erosion would be of lake deposited sediments in the Mendota Pool and of the Holocene age, the erosion would not likely affect paleontological resources. However, Alternative B may uncover Pleistocene-age fossil remains during construction-related earthmoving activities in the Project area. This impact would be **potentially significant**.

Mitigation Measures PAL-1 (Alternative B): ***Stop Work if Paleontological Resources Are Encountered During Earthmoving Activities and Implement Recovery Plan.*** Refer to Mitigation Measures PAL-1 (Alternative A). The same measures would be used here. This impact would be **less than significant** after mitigation.

Alternative C (Fresno Slough Dam with Narrow Floodplain and Short Canal)

Alternative C would include construction of Project features including Fresno Slough Dam, a new levee system with a narrow floodplain encompassing the river channel, and the Short Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the Short Canal control structure and fish screen, the Chowchilla Bifurcation Structure fish passage facility, modification of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 133-month timeframe.

Borrow material would primarily be required for the construction of the levees, but it may also be utilized in the construction of other structures for foundation or backfill material. Levees may be constructed entirely of local borrow material, a mix of local and imported borrow material, or just imported borrow material. Borrow locations would be determined after a geotechnical exploration of potential local borrow areas is complete; the exploration would determine the suitability of local soils for use as borrow material. It is estimated that up to 350 acres of land is needed for borrow areas. Some of the soils excavated to construct the Short Canal might be used for levee construction, and if this is possible, then the size of the borrow areas may be reduced.

Impact PAL-1 (Alternative C): ***Possible Damage to or Destruction of Unique Paleontological Resources.*** Refer to Impact PAL-1 (Alternative A). Potential impacts of Alternative C would be the same as potential impacts of Alternative A. This impact would be **potentially significant**.

Mitigation Measures PAL-1 (Alternative C): ***Stop Work if Paleontological Resources Are Encountered During Earthmoving Activities and Implement Recovery Plan.*** Refer to Mitigation Measures PAL-1 (Alternative A). The same measures would be used here. This impact would be **less than significant** after mitigation.

Alternative D (Fresno Slough Dam with Wide Floodplain and North Canal)

Alternative D would include construction of Project features including Fresno Slough Dam, a new levee system with a wide floodplain encompassing the river channel, and the North Canal. Other key features include construction of the Mendota Dam fish passage facility, the Fresno Slough fish barrier, the North Canal bifurcation structure and North Canal fish passage facility, removal of the San Joaquin River control structure at the Chowchilla Bifurcation Structure, removal of San Mateo Avenue crossing, and Main Canal and Helm Ditch relocations. Construction activity is expected to occur intermittently over an approximate 158-month timeframe.

Borrow material would primarily be required for the construction of the levees, but it may also be utilized in the construction of other structures for foundation or backfill material. Levees may be constructed entirely of local borrow material, a mix of local and

imported borrow material, or just imported borrow material. Borrow locations would be determined after a geotechnical exploration of potential local borrow areas is complete; the exploration would determine the suitability of local soils for use as borrow material. It is estimated that up to 350 acres of land is needed for borrow areas. Some of the soils excavated to construct the North Canal might be used for levee construction, and if this is possible, then the size of the borrow areas may be reduced.

Impact PAL-1 (Alternative D): ***Possible Damage to or Destruction of Unique Paleontological Resources.*** Refer to Impact PAL-1 (Alternative A). Potential impacts of Alternative D would be the same as potential impacts of Alternative A. This impact would be **potentially significant**.

Mitigation Measures PAL-1 (Alternative D): ***Stop Work if Paleontological Resources Are Encountered During Earthmoving Activities and Implement Recovery Plan.*** Refer to Mitigation Measures PAL-1 (Alternative A). The same measures would be used here. This impact would be **less than significant** after mitigation.

This page left blank intentionally.

19.0 Public Health and Hazardous Materials

This section describes the potential impacts that implementation of Project alternatives may have on public health and hazardous materials and explains the environmental setting, applicable regulatory framework, and appropriate mitigation measures.

19.1 Environmental Setting

This section describes the potential hazardous materials that would be handled, stored, and utilized and hazardous wastes that would be generated during Project construction. It also describes the procedures and engineering controls to be used to manage the Project's potential hazardous material and hazardous waste impacts to public health and the environment.

The Project area is located in Fresno and Madera Counties, near the city of Mendota, California. The Project includes the area of the San Joaquin River between the Chowchilla Bifurcation Structure and downstream of Mendota Dam in Fresno and Madera Counties, California. The size and location of the Project area, including the Project alternatives, are shown on Figure 1-2. The Project area includes land currently developed as farmland including row crops, orchards, and vineyards, and the associated roadway, utility, and drainage infrastructure. It also includes three farmhouses and associated outbuildings on the southeastern portion of the Project area.

Public health and hazardous materials include the following categories.

- Anthropogenic materials found at the site before the start of Project construction including vehicular fuels, other vehicular fluids such as antifreeze, lubricants, hydraulic fluid, and residual pesticide and herbicide impacts from past agricultural land uses.
- Anthropogenic materials used during construction or operation of the Project such as vehicular fuels and other vehicular fluids such as antifreeze, lubricants, and hydraulic fluid.
- Naturally occurring hazardous materials at the site such as metals, asbestos, and biological hazards in the soils.
- Project generated wastes, such as construction debris from the demolition of the existing structures within the Project area, including wood, roofing materials, metal, brick, cinder block, etc., contaminated soil from areas around potentially leaking underground storage tanks, waste treated wood from utility poles, fence posts, and grape stakes, metal from fencing and metal fence posts, and asphalt and concrete from roadway and building foundation removal.

19.1.1 Known Hazardous Material Sites

The San Joaquin River Restoration Program (SJRRP) retained Environmental Data Research to conduct an environmental regulatory agency database search to evaluate past and current project and surrounding land uses that may have potentially contributed to site contamination for the Project area. Various Federal and State regulatory databases were researched as part of the Draft Phase I Environmental Site Assessment (Appendix 19-A). The Draft Phase I Environmental Site Assessment included a review of historical aerial photographs and topographic maps of the Project area. A copy of the Phase I Environmental Site Assessment is provided in Appendix 19-A.

The database search of facilities on the Federal and State lists was reviewed for information on whether hazardous substances, wastes, or petroleum products have been improperly handled, stored, or disposed on the Project footprint and adjacent properties. The following sites were identified as hazardous material sites within the Project area or on the boundary of the Project area in the database report. These sites are described below.

- Paramount Farming Company, 10317 Eastside Drive, Firebaugh, CA.
- Mendota Solid Waste Disposal, ½ mile east of Bass Avenue, Mendota, CA.
- Frank A Logoluso Farms, 2369 San Mateo Avenue, Mendota, CA.
- AES Mendota/Covanta Mendota LP, 400 Guillen Parkway, Mendota, CA.

Paramount Farming Company, at 10317 Eastside Drive in Firebaugh, CA, is located on the northern boundary of the Project area. This site was listed in the Hazardous Waste Tracking System database, a California Department of Toxic Substances Control (DTSC) database of hazardous waste manifests (DTSC 2015). This site has been identified as having 2.4 tons of asbestos containing waste, and the disposal method is listed as landfill or surface impoundment that will be closed as a landfill (to include on-site treatment and/or stabilization). The site represents a potential environmental concern to the Project area due to the presence of asbestos containing waste.

Mendota Solid Waste Disposal facility is located ½ mile east of Bass Avenue, near Fresno Slough in Mendota, CA. The site is located on the southwestern boundary of the Project area, near Mendota Pool. The site was listed in the California Department of Resources, Recycling, and Recovery (CalRecycle) Solid Waste Information System database as a Solid Waste Facility/Landfill site. The Mendota Solid Waste Disposal facility was a permitted solid waste disposal site that was clean closed on December 31, 1981. The site is not expected to represent an environmental concern to the Project area.

Frank A. Logoluso Farms, at 2369 San Mateo Avenue in Mendota, CA, is located within the Project area south of the San Joaquin River. This site was listed in the Hazardous Waste Tracking System database, a DTSC database of hazardous waste manifests. This site has been identified as having 0.3753 tons of waste oil and mixed oil. The site is not expected to represent an environmental concern to the Project area.

AES Mendota/Covanta Mendota LP facility, at 400 Guillen Parkway in Mendota, CA, is located on the western boundary of the Project area, near Mendota Airport. The biomass power plant was listed in several Federal and State databases. The AES Mendota/Covanta Mendota LP facility is located downgradient of the Project area and on the southwestern boundary; therefore, the site is not expected to represent an environmental concern to the Project area.

The following historic recognized environmental condition was identified in connection with the Project area. Because the Project area was historically used as farmland, pesticide and herbicide residuals may be present in the soil. However, features were not identified (e.g., impoundments, bulk storage facilities or crop dusting air strips) that suggested the handling or storage of significant quantities of pesticides and/or herbicides in the Project area.

19.1.2 Exposure to Disease

Public health hazards also include exposure to disease vectors. Diseases found in the Project vicinity include West Nile virus (WNV), Hantavirus, and valley fever.

Exposure to West Nile Virus

All mosquito species are potential vectors that can cause disease to pets, domestic animals, wildlife, and humans. Public concern regarding WNV, a disease transmitted to humans, has increased since the virus was first detected in the United States in 1999. WNV is mosquitos borne arbovirus that is not transmitted from person to person contact. Approximately 20 percent of infected persons develop symptoms. There were 2,765 cases reported in California from 2003 to 2008 (California Department of Public Health [CDPH] 2010). A mosquito acquires WNV by feeding on the blood of infected birds. All species of mosquitoes require standing water to complete their growth cycle; therefore, any standing body of water represents a potential mosquito breeding area. WNV is transmitted by infected mosquito bites.

Local mosquito abatement districts implement controls such as spraying to protect public health. In Madera County, the mosquito abatement district is the Madera County Mosquito and Vector Control District located in Madera. In Fresno County, the mosquito abatement district is the Fresno Westside Mosquito Abatement District in Firebaugh.

Exposure to Hantavirus

Hantavirus is an often fatal lung disease transmitted by rodents. It is transmitted in California only by deer mice. Most transmittal to humans is through breathing air contaminated with rodent droppings or urine. This happens most frequently in small closed spaces. Infrequent transmittal occurs from consuming food contaminated with rodent droppings or urine or touching surfaces contaminated with rodent dropping or urine and then putting fingers in the mouth, or being bitten by an infected rodent (CDPH 2009a). Demolition of buildings may expose workers to rodent wastes that may be contaminated with Hantavirus.

Exposure to Valley Fever

Valley fever is caused by a fungus that usually affects the lungs. People become infected by breathing dust contaminated with the fungal spores. Approximately 150,000 cases occur in the United States annually, although approximately half of the cases do not produce symptoms. It is not transmitted from person to person (CDPH 2009b).

19.2 Regulatory Setting

This section discusses the regulatory setting for public health and hazardous materials in the Project area.

19.2.1 Federal

Table 19-1 provides a summary of Federal environmental hazardous materials laws, ordinances and regulations, and indicates the agencies providing regulatory oversight. Selected Federal laws and regulations pertaining to public health and hazardous materials in the Project area are also discussed briefly below.

Table 19-1.
Summary of Federal Regulations Applicable to Hazardous Materials/Waste Handling

Authority	Administering Agency	Requirements and Compliance
CERCLA, as amended by SARA; Title III, Emergency Planning and Community Right-to-Know Act of 1986, 42 USC 11001 et seq., 40 CFR Parts 302, 355, 370, and 372.	EPA Region IX; National Response Center; California OES; Fresno County Department of Public Health - Environmental Health Division; Madera County Department of Environmental Health	CERCLA release notification requirements; SARA Title III includes reporting requirements for storing, handling, or producing regulated substances.
29 CFR 1910 et seq. 29 CFR 1926 et seq.	Occupational Safety and Health Administration (OSHA)	Requirements pertaining to employers whose employees handle hazardous materials and extremely hazardous chemicals.
Clean Air Act Amendments of 1990, Section 112(r), Accidental Release Prevention Program, 42 USC 7412 (r), 40 CFR Part 68	EPA Region IX; California OES; Fresno County Department of Public Health - Environmental Health Division; Madera County Department of Environmental Health	Requirements pertaining to risk management of regulated substances.
Clean Water Act, Spill Prevention, Control, and Countermeasure Plan, 40 CFR 112	EPA Region IX, Fresno County Department of Public Health - Environmental Health Division; Madera County Department of Environmental Health	Requirements designed to prevent the discharge of oil into navigable waters.
RCRA, 42 USC 6901 et seq., 40 CFR 260 et seq., 49 CFR 172, 173, and 179	EPA Region IX	Requirements for a hazardous waste generator identification number coordinated through the EPA and the DTSC.

Key:
CERCLA = Comprehensive Environmental Response, Compensation, and Liability Act of 1980
CFR = Code of Federal Regulations
DTSC = California Department of Toxic Substances Control
EPA = U.S. Environmental Protection Agency
OES = Office of Emergency Services
OSHA = Occupational Safety and Health Administration
RCRA = Resource Conservation and Recovery Act
SARA = Superfund Amendments and Reauthorization Act of 1986
USC = United States Code

Hazardous Materials Handling

At the Federal level, the principal agency regulating the generation, transport, and disposal of hazardous substances is U.S. Environmental Protection Agency (EPA), under the authority of the Resource Conservation and Recovery Act (RCRA). The RCRA established an all-encompassing Federal regulatory program for hazardous substances that is administered by EPA. Under the RCRA, EPA regulates the generation, transportation, treatment, storage, and disposal of hazardous substances. The RCRA was amended in 1984 by the Hazardous and Solid Waste Amendments of 1984, which specifically prohibits the use of certain techniques to dispose of various hazardous substances. The Federal Emergency Planning and Community Right to Know Act of 1986 imposes hazardous-materials planning requirements to help protect local communities in the event of accidental release of hazardous substances. EPA has delegated much of the RCRA requirements to the DTSC.

Worker Safety Requirements

The U.S. Department of Labor, Occupational Safety and Health Administration (OSHA), is responsible at the Federal level for ensuring worker safety. OSHA sets Federal standards for implementing workplace training, exposure limits, and safety procedures for the handling of hazardous substances (as well as other hazards). OSHA also establishes criteria by which each state can implement its own health and safety program.

Regulation of Polychlorinated Biphenyls

The Toxic Substances Control Act of 1976 (United States Code [USC] Title 15, Section 2605) banned the manufacture, processing, distribution, and use of polychlorinated biphenyls (PCBs) in totally enclosed systems. The EPA Region 9 PCB Program regulates remediation of PCBs in several states, including California. Title 40 of the Code of Federal Regulations (CFR), Section 761.30(a)(1)(vi)(A) states that all owners of electrical transformers containing PCBs must register their transformers with EPA. Specified electrical equipment manufactured between July 1, 1978, and July 1, 1998, that does not contain PCBs must be marked by the manufacturer with the statement “No PCBs” (Section 761.40[g]). Transformers and other items manufactured before July 1, 1978, and containing PCBs must be marked as such.

Asbestos

The Federal Clean Air Act (CAA) was enacted in 1970. The most recent major amendments by Congress were made in 1990. The CAA required EPA to establish primary and secondary national ambient air quality standards. It also required each state to prepare an air quality control plan, referred to as a State Implementation Plan. Section 112 of the CAA defines "hazardous air pollutants" and sets threshold limits. Asbestos-containing substances are regulated by EPA under the CAA. Additional information about the CAA is presented in Chapter 4.0, "Air Quality."

Airport and Airspace Safety

Part 77 of the Federal Aviation Regulations, "Objects Affecting Navigable Airspace," has been adopted as a means of monitoring and protecting the airspace required for safe operation of aircraft and airports. Objects that exceed certain specified height limits constitute airspace obstructions. Federal Aviation Regulations Section 77.13 requires that the Federal Aviation Administration be notified of proposed construction or alteration of certain objects in a specified vicinity of an airport.

19.2.2 State of California

Table 19-2 provides a summary of State environmental hazardous materials laws, ordinances and regulations, and indicates the agencies providing regulatory oversight. Selected State laws and regulations pertaining to public health and hazardous materials in the Project area are also discussed briefly below.

Table 19-2.
Summary of State Regulations Applicable to Hazardous Materials/Waste Handling

Authority	Administering Agency	Requirements and Compliance
California Health & Safety Code, Chapter 6.95, Art. 1	Fresno County Department of Public Health - Environmental Health Division; Madera County Department of Environmental Health	Facilities handling hazardous materials are required to submit a Hazardous Materials Business Plan (HMBP) to the Certified Uniform Program Agency.
California Health & Safety Code § 25270	Central Valley Regional Water Quality Control Board	Above ground petroleum storage tanks must be registered with the State Water Resources Control Board.
8 CCR § 5194	Fresno County Department of Public Health - Environmental Health Division; Madera County Department of Environmental Health	Requirements pertaining to employers whose employees are exposed to dusts, fumes, mists, vapors, and gases.
California Health & Safety Code §§ 25500–25520; 19 CCR §§ 2720–2734	Fresno County Department of Public Health - Environmental Health Division; Madera County Department of Environmental Health	Requirement to prepare an HMBP.
California Accidental Release Prevention Program, California Health & Safety Code § 25531 et seq., 19 CCR Division 2, Chapter 4.5	California OES, Fresno County Department of Public Health - Environmental Health Division; Madera County Department of Environmental Health	HMBP requirements and requirements to prepare a risk management plan.

Table 19-2.
Summary of State Regulations Applicable to Hazardous Materials/Waste Handling

Authority	Administering Agency	Requirements and Compliance
8 CCR § 339, § 3200 et seq., § 5139 et seq., § 5160 et seq., § 5189 et seq.	Cal/OSHA	Requirements pertaining to the control and management of hazardous substances.
Hazardous Waste Control Act, California Health & Safety Code; 22 CCR § 66001 et seq.	Fresno County Department of Public Health - Environmental Health Division; Madera County Department of Environmental Health	Requirements pertaining to the management of hazardous waste.
22 CCR § 67100, Hazardous Waste Source Reduction and Management Review	Fresno County Department of Public Health - Environmental Health Division; Madera County Department of Environmental Health	Requirements pertaining to waste generators developing a plan for reducing their hazardous wastes.
22 CCR §§ 66260-66270	Fresno County Department of Public Health - Environmental Health Division; Madera County Department of Environmental Health	Requirements pertaining to hazardous waste regulations for generators and transporters of hazardous wastes and owners of hazardous waste Treatment, Storage, and Disposal Facilities.
Porter-Cologne Water Quality Control Act	Central Valley Regional Water Quality Control Board	Reportable quantities of hazardous wastes and hazardous materials are established by the RWQCB based on their potential to degrade the waters of the state.
Uniform Fire Code, Article 80 and others	Fresno County Fire Protection District; Madera County Fire Department	Provisions regarding fire protection and neutralization systems for hazardous materials.
California Vehicle Code § 32100.5	Caltrans	Requirements for transportation materials that may pose an inhalation hazard.
State Building Standard Code	Various agencies	Requirements pertaining to fire prevention, building safety, etc.

Key:
Cal/OSHA = California Occupational Safety and Health Administration
Caltrans = California Department of Transportation
CCR = California Code of Regulations
HMBP = Hazardous Material Business Plan
OES = Office of Emergency Services
RWQCB = Regional Water Quality Control Board

Hazardous Materials Handling

The California Hazardous Materials Release Response Plans and Inventory Law of 1985 requires preparation of hazardous materials business plans and disclosure of hazardous materials inventories. A business plan includes an inventory of hazardous materials handled, facility floor plans showing where hazardous materials are stored, an emergency response plan, and provisions for employee training in safety and emergency response procedures (Health & Saf. Code, Div. 20, Ch. 6.95, Art. 1). Statewide, DTSC has primary regulatory responsibility for managing hazardous materials, with delegation of authority to local jurisdictions that enter into agreements with the State. Local agencies administer these laws and regulations.

Worker Safety Requirements

California Occupational Safety and Health Administration (Cal/OSHA) assumes primary responsibility for developing and enforcing workplace safety regulations in California. Cal/OSHA regulations pertaining to the use of hazardous materials in the workplace (Cal. Code Regs., tit. 8) include requirements for safety training, availability of safety equipment, accident and illness prevention programs, hazardous substance exposure warnings, and preparation of emergency action and fire prevention plans.

Emergency Response to Hazardous Materials Incidents

California has developed an emergency response plan to coordinate emergency services provided by Federal, State, and local governments and private agencies. Response to hazardous material incidents is one part of this plan. The plan is managed by the Governor's Office of Emergency Services (OES), which coordinates the responses of other agencies, including the California Environmental Protection Agency (Cal/EPA), California Highway Patrol (CHP), California Department of Fish and Wildlife, and Central Valley Regional Water Quality Control Board.

Hazardous Materials Transport

The U.S. Department of Transportation (DOT) regulates transportation of hazardous materials between states. State agencies with primary responsibility for enforcing Federal and State regulations and responding to hazardous materials transportation emergencies are the CHP and California Department of Transportation (Caltrans). Together, these agencies determine container types used and license hazardous waste haulers for transportation of hazardous waste on public roads.

The DOT Federal Railroad Administration enforces the hazardous materials regulations, which are promulgated by the Pipeline and Hazardous Materials Safety Administration for rail transportation. These regulations include requirements that railroads and other transporters of hazardous materials, including shippers, have and adhere to security plans and train their employees involved in offering, accepting, or transporting hazardous materials on both safety and security matters.

California Accidental Release Prevention Program

The goal of the California Accidental Release Prevention Program is to reduce the likelihood and severity of consequences of extremely hazardous materials releases. Any business that handles regulated substances (chemicals that pose a major threat to public health and safety or the environment because they are highly toxic, flammable, or explosive, including ammonia, chlorine gas, hydrogen, nitric acid, and propane) is required to prepare a risk management plan. A risk management plan describes current and past practices and releases, what the impact of releases may be, and what the business does or plans to do to prevent releases and minimize their impact if they occur.

Government Code Section 65962.5 (Cortese List)

The provisions of Government Code section 65962.5 are commonly referred to as the "Cortese List" (after the legislator who authored the legislation that enacted it). The *Cortese List* is a planning document used by State and local agencies to comply with California Environmental Quality Act (CEQA) requirements in providing information

about the location of hazardous materials release sites. Government Code section 65962.5 requires Cal/EPA to develop an updated *Cortese List* annually at minimum. DTSC is responsible for a portion of the information contained in the *Cortese List*. Other California State and local government agencies are required to provide additional hazardous material release information for the *Cortese List*.

Multi-Hazard Mitigation Plan

OES issued the *State of California Multi-Hazard Mitigation Plan* (OES 2013) in October 2013. It provides an updated and comprehensive description of California's historical and current hazard analysis, mitigation strategies, goals and objectives. The Federal Disaster Mitigation Act required all State emergency services agencies to issue such plans by November 1, 2004, for the states to receive Federal grant funds for disaster assistance and mitigation under the Stafford Act (44 CFR 201.4).

Public Resources Code and California Code of Regulations, Title 14, Chapter 4

California Department of Conservation Division of Oil, Gas, and Geothermal Resources (DOGGR) is responsible for section 3000 et seq. of the Public Resources Code and California Code of Regulations, Title 14, Chapter 4, which address the drilling, operation, maintenance, plugging, and abandonment of onshore and offshore oil, gas, and geothermal wells. In addition, DOGGR's programs include well permitting and testing, safety inspections, oversight of production and injection projects, environmental lease inspections, idle-well testing, inspecting oilfield tanks, pipelines, and sumps, hazardous and orphan well plugging and abandonment contracts, and subsidence monitoring (DOGGR 2012).

19.2.3 Regional and Local

Regional or local plans pertain to public health and hazardous materials in the Project area are discussed below.

General Plans

The Fresno County General Plan (Fresno County 2000) and the Madera County General Plan (Madera County 1995) identify goals and policies that describe approaches to public health and hazardous materials used by each county. The Fresno County General Plan Health and Safety element sets policies on wildland fires (Policies HS-B.1 and HS-B.5), airport hazards (Policy HS-E.1), and hazardous materials (Policy HS-F.5). Similarly, the Madera County General Plan provides policies on emergency services and fire protection (Policies 3.G.5, 3.H.2, and 6.C.10), airport hazards (Policy 6.D.1), and hazardous materials (Policies 6.G.4 and 6.G.5).

19.3 Environmental Consequences and Mitigation Measures

This section describes how the potential hazards and hazardous materials impacts are evaluated, what the impacts may be, and how the impacts would be mitigated.

19.3.1 Impact Assessment Methodology

This section provides the methodology that was used to evaluate the potential human health and environmental impacts of hazardous materials related to the Project.

Various Federal and State regulatory databases were researched for past and current land uses that may have potentially contributed to site contamination for the environmental setting/existing conditions section. A Phase I Environmental Site Assessment (Phase I) was conducted on the Project area to evaluate past and current land uses that may have potentially contributed to site contamination that could impact Project construction or have longer term impacts on Project operation. Various Federal and State of California regulatory databases were researched as part of this Phase I effort.

Federal, State, and local statutes regulating hazardous waste were reviewed for the analysis of potential impacts associated with hazards and hazardous materials. The applicable regulations establish handling and management requirements associated with hazards and hazardous materials management.

The transport, use, and disposal of hazardous materials that may be involved in Project construction were described. The potential for upset or accidents involving hazardous materials on the Project site during and after construction completion was discussed. The emission of hazardous or acutely hazardous materials from the Project during and after construction within ¼ mile of an existing school was evaluated. The locations of known hazardous waste sites in the Project area were evaluated; this evaluation included oil and gas wells in the area. The potential impacts of the use of hazardous materials and/or site construction work on public airports within 2 miles of the Project was evaluated. Potential impacts to private airstrips near the Project were discussed. Potential impacts to implementation of local emergency response plans were evaluated. The Project's potential to contribute or cause wildland fires (from the operation of construction equipment) were evaluated.

19.3.2 Significance Criteria

The thresholds of significance for impacts are based on the Environmental Checklist Form in Appendix G of the State CEQA Guidelines, as amended. These thresholds also encompass the factors taken into account under the National Environmental Policy Act (NEPA) to determine the significance of an action in terms of its context and the intensity of its effects. Impacts resulting from the Project would be significant if they would cause any of the following:

- Create a substantial hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials.
- Create a substantial hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment.
- Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within ¼ mile of an existing or proposed school.

- Be located on a site that is included on a list of hazardous materials sites compiled pursuant to Government Code section 65962.5 and, as a result, would create a substantial hazard to the public or the environment.
- Result in a safety hazard for people residing or working in the Project area for areas designated in an airport land use plan, within 2 miles of an airport, or in the vicinity of a private airstrip.
- Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan.
- Expose people or structures to a substantial risk of loss, injury, or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands.
- Expose people to new or increased risk from disease vectors.

19.3.3 Impacts and Mitigation Measures

This section provides an evaluation of the long-term and temporary effects of the Project alternatives on public health and hazardous materials. It includes analyses of potential effects relative to No-Action conditions in accordance with NEPA and potential impacts compared to existing conditions to meet CEQA requirements. With respect to public health and hazardous materials, the environmental impact issues and concerns are:

1. Creation of a Substantial Hazard through the Routine Transport, Use, or Disposal of Hazardous Materials or through Reasonably Foreseeable Upset and Accident Conditions Involving the Release of Hazardous Materials.
2. Increased Exposure to Hazardous Materials of People Residing or Working in the Project Area.
3. Creation of a Substantial Hazard from Disturbance of Known Hazardous Material Sites.
4. Creation of a Substantial Hazard from Mobilization of Soil Contaminants on the Floodplain.
5. Exposure of People to Increased Risk of Diseases.
6. Creation of a Substantial Hazard from Decommissioned Wells.
7. Increased Hazardous Emissions or Handling of Hazardous Materials, Substances, or Wastes within ¼ mile of a School.
8. Exposure of People or Structures to a Substantial Risk of Loss, Injury, or Death involving Wildland Fires.
9. Creation of a Substantial Hazard in Areas Designated by Airport Land Use Plans, within 2 miles of an Airport, or in the Vicinity of a Private Airstrip.
10. Impairment of the Implementation or Physical Interference with an Adopted Emergency Response or Emergency Evacuation Plan.

Other public health and hazardous materials related issues covered in the Program Environmental Impact Statement/Report are not covered here because they are

programmatic in nature and/or are not relevant to the Project area. This includes mobilization of naturally occurring asbestos.

Issues Eliminated from Further Analysis

Mobilization of Naturally Occurring Asbestos. Inhalation of naturally occurring asbestos can cause lung cancer and other long-term respiratory problems. Due to local Project area geology, it is unlikely that naturally occurring asbestos is present in the site soils. Therefore, impacts from naturally occurring asbestos are not evaluated.

No-Action Alternative

Under the No-Action Alternative, the Project would not be implemented and none of the Project features would be developed in Reach 2B of the San Joaquin River. However, other proposed actions under the SJRRP would be implemented, including habitat restoration in other reaches, augmentation of river flows, and reintroduction of salmon. Without the Project in Reach 2B, however, these activities would not achieve the Settlement goals. The potential effects of the No-Action Alternative are described below. The analysis is a comparison to existing conditions, and no mitigation is required for No-Action.
